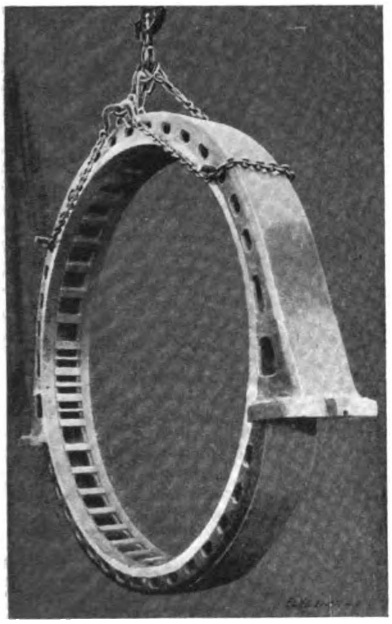
The Edison Electric Illuminating Co. of Brooklyn.—Its Development and Its Present and Future Work.

BY

Jos. Wetzler.

INTRODUCTORY



Armature Frame, 2,000 k. w. 3-phase Generator.

NWARD, ever onward, is the electrician's watch word. What was considered chimerical in electricity twenty-five years ago is now part of our daily experience. Indeed, less than twenty-five years have passed since men high in the scientific world demonstrated mathematically that Mr. Edison's incandescent lamps could never be operated commercially; and yet there are a hundred million such lamps in use and most of them burning nightly. When it comes to apparatus for generating and distributing electric current, even so short a period as ten years back seems a long time if one compares the apparatus and methods then in vogue with those of to-day. Yes, even five years ago the new Union Station of the Brooklyn Edison Co., would have been considered too great an innovation for serious contemplation, yet now we look upon it as just the thing and the electrical engineers of the whole country look upon Brooklyn as blazing the path of future progress in central station and electrical distribution work of every kind, whether it be for light or power, or other purposes.

It is not our intention, even if space permitted it, to go back to the electrical year 1, and trace the details of the great advances which have converted the end of the century into an electrical age; our object is a different one, and in its way, quite as interesting and instructive. For to us, the growth within the limits of a city, of an industry ministering to the comforts as well as to the necessities of its citizens, and destined to still further increase its sphere of usefulness, giving new employment to hundreds and even thousands and involving the investment of millions of dollars,—all this, seems to us a subject full of living interest, and the more so when the record of such an enterprise is one of constant, upward growth.

Such is the history of the Edison Electric Illuminating Co., of Brooklyn, whose work and equipment we propose to present to our readers in the following necessarily brief account—

THE NEW UNION STATION, FROM NEW YORK HARBOR.

for to go into detail on what is barely outlined in these few pages, would require a good-sized volume of the Engineer.

HISTORICAL AND STATISTICAL.

It was shortly after Mr. Edison had shown the world that an incandescent lamp could be made to last more than a few hours and had proved that the current could be distributed, practically and economically, underground, that a number of public-spirited and enterprising citizens of Brooklyn harbored the idea of conferring upon their own city the benefits of the new discoveries and inventions. But though the idea in itself was applauded and there was no lack of moral encouragement for the undertaking, capital was shy and preferred to wait in order to see what "the other fellow" was doing.

It had been easy enough, previously, to find men willing to invest money in electric lighting stations operating with overhead conductors and furnishing arc lights almost exclusively; but the laying down of a system designed from the start to be entirely below the street surface and entailing corresponding cost and designed primarily for incandescent lighting—the electric motor had barely begun to loom up—required, in a scattered territory like Brooklyn, courage of no small nature. Under the leadership of such men as Mr. Eugene Crowell, Mr. Ethan Allen Doty, Mr. George Foster Peabody, and those directly associated with them, the necessary capital was subscribed and in 1889 was begun the erection of the "First District" Edison station in Brooklyn.

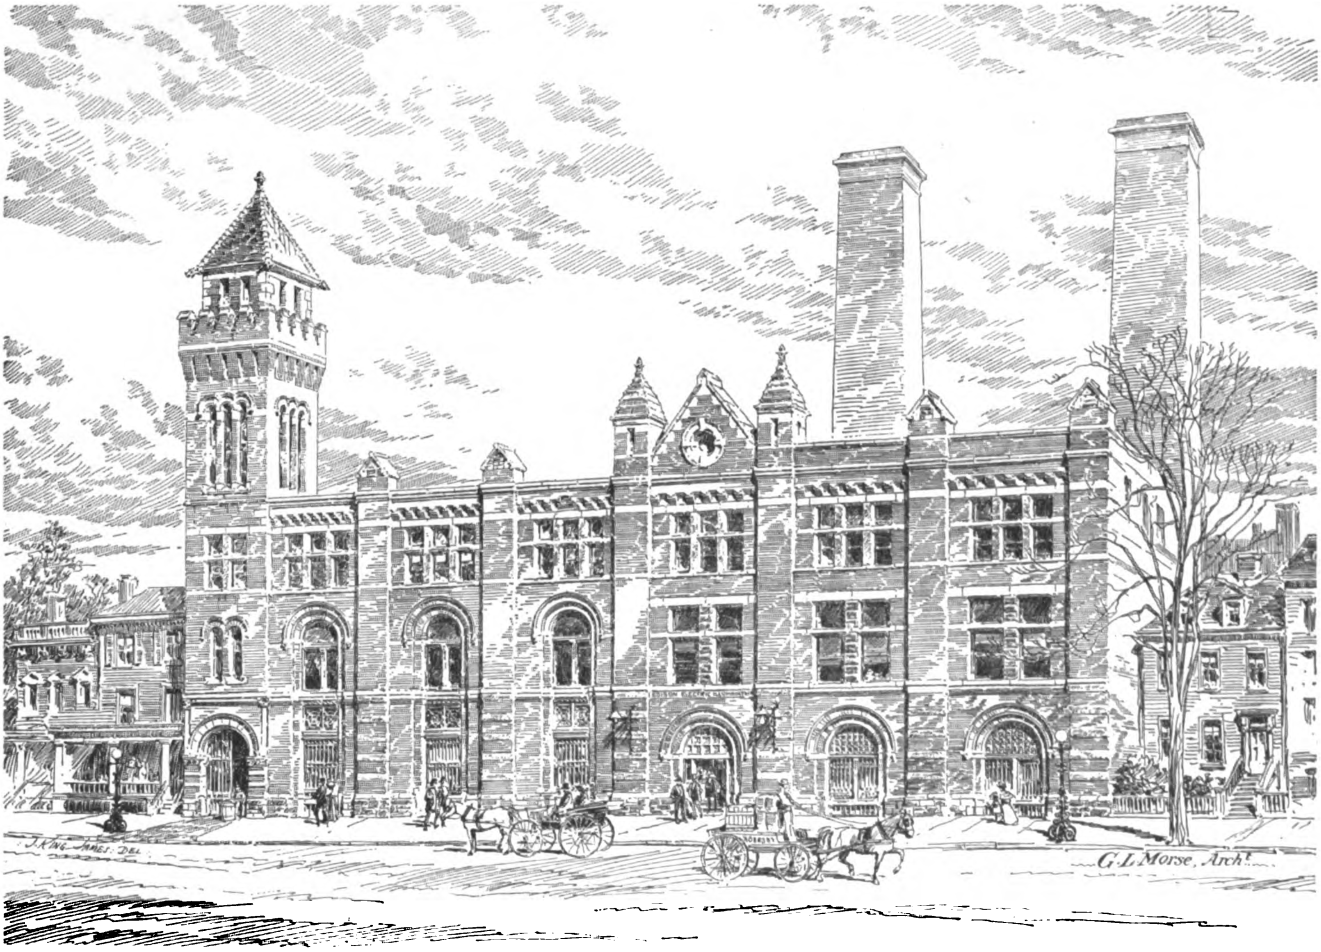
This station, situated on Pearl street, not far from the City Hall, was erected under the supervision of the company's first general superintendent, Mr. C. J. Field, and started with 6,600 lamps connected. The first year showed little profit,—none, indeed, was expected—but at the end of that period the equivalent number of lamps connected had risen from 6,600 to 25,170 16 c. p. lamps, distributed as follows: 17,356 incandescent lamps, 590 arc lights, 156½ h. p. in motors.

Encouraged by the rapid increase of business the stockholders authorized an increase of $900,000 in stock and $500,000 in bonds, paid for at par, and with the money thus realized the First District station was enlarged, and in addition a new station, the Second District, was established.

During this first year of operation the Brooklyn Edison Co. inaugurated a practice which has now become universal, and that is, the operation of arc lamps from low tension circuits. The success of this system was instantaneous and Brooklyn has from the very start kept ahead of its sister cities in the number of arc lamps operated in this manner.

It was shortly after the First District station went into operation that Mr. W. S. Barstow was appointed general superintendent.

The second year's operation was the turning point in the company's affairs. The number of equivalent lamps connected rose to 41,379, additions of an extensive character were made in station equipment and, what was most important, the payment of dividends was begun, at the rate of 4 per cent. per annum. Since then dividends have been paid continuously, rising during the last four years to the rate of 6 per cent. per annum.



FIRST DISTRICT STATION, EDISON ELECTRIC ILLUMINATING CO., BROOKLYN.

It would lead us too far to follow in detail the work of the company year by year. Suffice it to say that it has been one continuous record of improvement and progress which can be shown in no better way than by a glance at the accompanying table exhibiting the number of lamps, arc and incandescent, and of motors, connected, from 1890 to the present time.

	Incand. 16 c. p. equiv.	Arcs. low ten.	Motors. H.P.	Arcs. high ten.
Jan. 1, 1890	6,000	....	....	...
Jan. 1, 1892	26,753	908	430	...
Jan. 1, 1894	55,581	2,708	1,424	...
Jan. 1, 1896	84,818	3,284	2,623	1,897
Jan. 1, 1898	103,591	4,032	3,702	1,939

The last figures above represent the combined present output of the six Edison stations and substations as well as that of the Citizens' Electric Illuminating Co., which was acquired by

purchase in 1896. That figure, however, does not represent the full capabilities of the company by any means, as these have been immensely increased by the erection of the great new Union Station at Bay Ridge, of which more anon.

Before entering into a description of the company's latest work we propose to devote some space to a description of the Brooklyn Edison Co.'s older stations, so that our readers may gain an adequate survey of the situation in which the company found itself about a year ago, and which led to the adoption of its new 3-phase system and the erection of the great Union Station.

THE FIRST DISTRICT STATION.

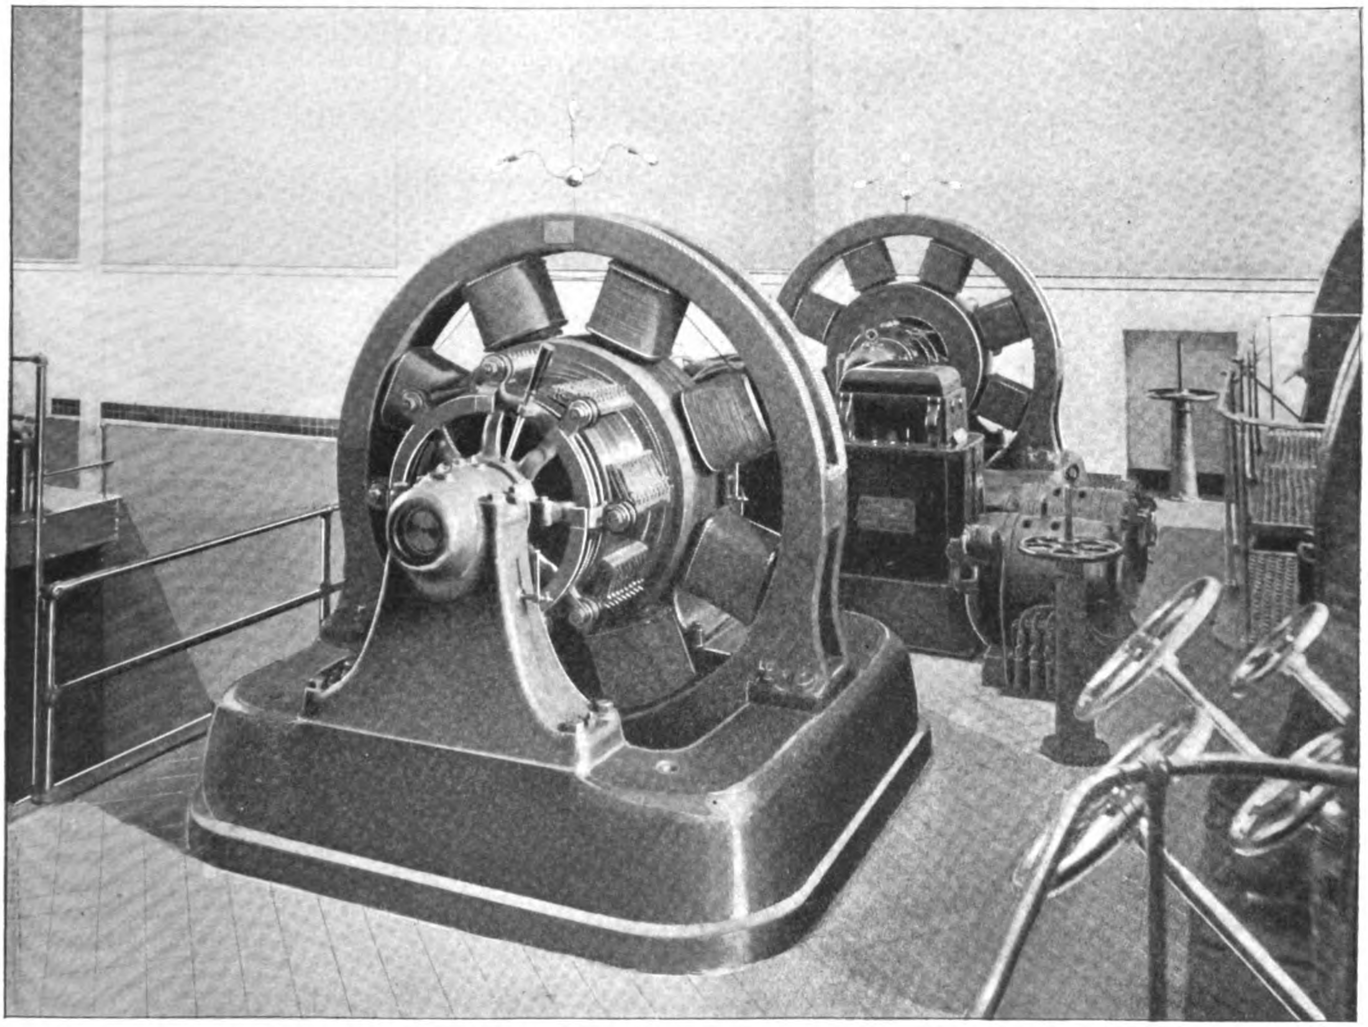
This station, known as the Pearl street station, was originally designed and erected in 1889 for an ultimate capacity of 3,000 h. p. In 1893 an addition, doubling the size of the building, was erected, and at the same time provision was made for remodeling the entire plant to accommodate vertical compound condensing engines, directly connected to multipolar generators.

The building as now finished is 150 feet front by 100 feet deep. The first floor is divided longitudinally into two rooms, one 70x100 feet, containing the engine and generator plant, switchboard gallery, etc.; the other, 71x100 feet, containing the boiler plant, above mentioned. The engine room has a height of 30 feet, while this corresponding height in the boiler room is occupied by boilers and coal storage bins.

A separate entrance to the building leads to the floor over the coal storage and engine room, where are located the offices of the company. These offices provide comfortable quarters for the president, secretary and treasurer, general superintendent, assistant secretary, auditor, bookkeeping department, meter department, purchasing agent, building department, canvassing department, testing department, machinists, street department, emergency and inspection department, steam department and electrical department.

This station, as remodeled in 1893, contains two units, each of 750 h. p., vertical cross-compound condensing Lake Erie Engineering Works engines, directly connected to two 200 k. w. Edison multipolar generators. Also two 1,200 h. p. vertical, three-cylinder, compound condensing engines, built by William Tod & Co., of Youngstown, Ohio, each being directly connected to two 400 k. w. Edison multipolar generators. All of these engines were designed by Mr. E. F. Williams, of New York.

In addition to these units there remained, as part of the old equipment, two 250 h. p. cross-compound Ball engines, built by the Ball Engine Co., Erie, Pa., originally installed in 1889, belted each to two 100 k. w. Edison bipolar generators.



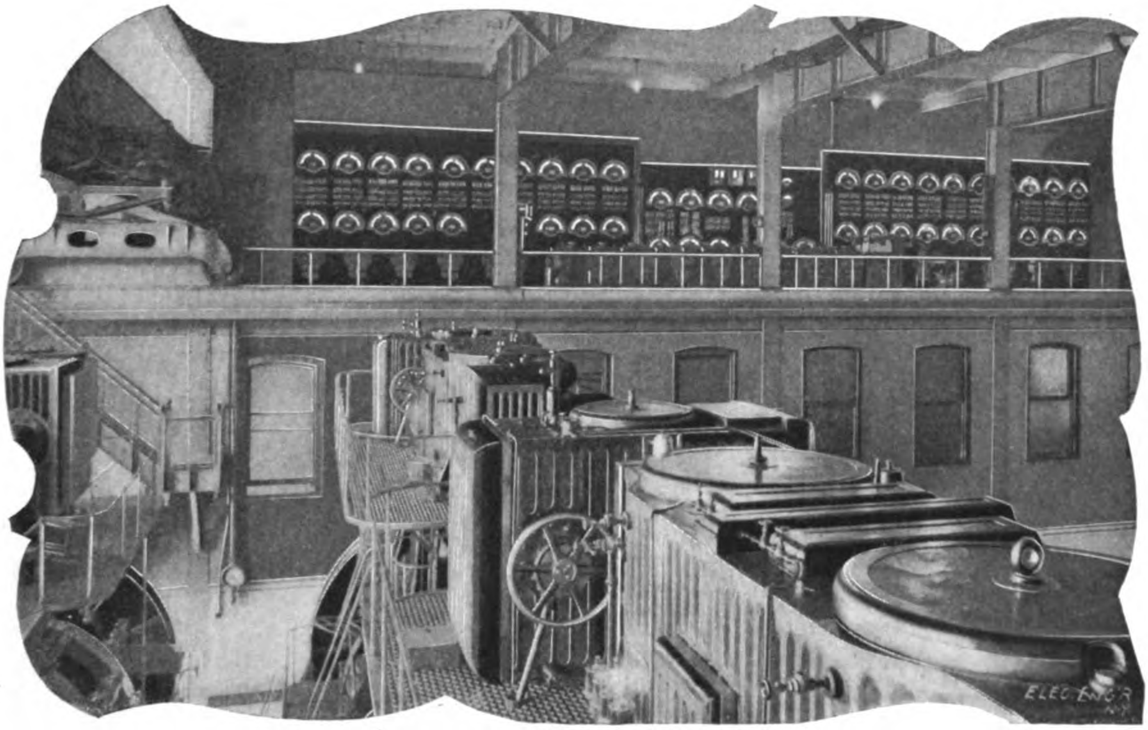
GENERAL ELECTRIC 400 K. W. ROTARY AND STATIC TRANSFORMER UNIT, FIRST DISTRICT STATION.

The steam for these engines is delivered from eight 240 h. p. Babcock & Wilcox boilers, furnished by the Babcock & Wilcox Company, one 600 h. p. Morrin vertical boiler and one 600 h. p. Columbia vertical boiler.

The condensing water for the plant is obtained from a Worthington self-cooling condensing equipment. This plant is interesting in that it is the largest self-cooling condenser plant in operation in the United States. The towers, as will be seen, on page 5, are placed upon the roof of the station at an elevation above the engine room of about 80 feet. They are two in number, having a total capacity of 5,000 horse power. The condensing apparatus, as shown on page 4, operates upon a new system that is especially adapted to large stations where there are a number of engines exhausting into a main exhaust trunk. Its principal feature is that the water from the condensation of the steam is pumped out of the condenser automatically by a water pump, while the air that leaks into

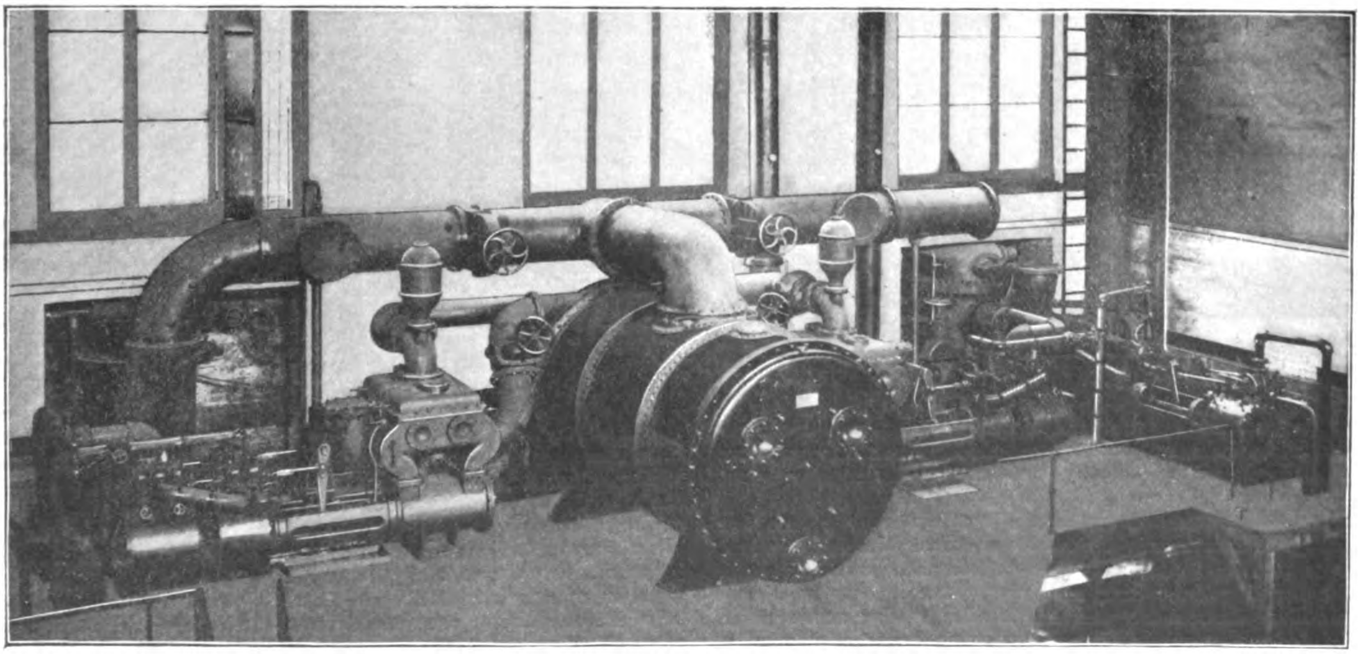
the system is pumped from the closed hot well by means of an air pump specially designed for pumping air alone. The highest vacuum is in this way obtained, and the speed of the latter pump is commensurate to the amount of air leakage, while the hot water pump simply removes the water that is condensed from the exhaust steam.

were on the same level as the condensing apparatus. The eight 6-foot air circulating fans of the cooling towers are driven by means of two electric motors so arranged as to be capable of being run in series or in multiple, and in connection with one or with both towers, as the condition of service may require.



HIGH AND LOW TENSION SWITCHBOARD IN FIRST DISTRICT STATION.

The surface condenser, which occupies a central position in this plant, has 8,000 square feet of cooling surface, the steam being exhausted around the tubes, and the cold water from the towers at an elevation of 80 feet is circulated by means of the circulating pumps through the tubes and back again to the top of the tower. In this way the power of the descending column is used to assist the ascending column, so that the real work done by the circulating pump is only the height of the towers, and the economical result is the same as if the towers



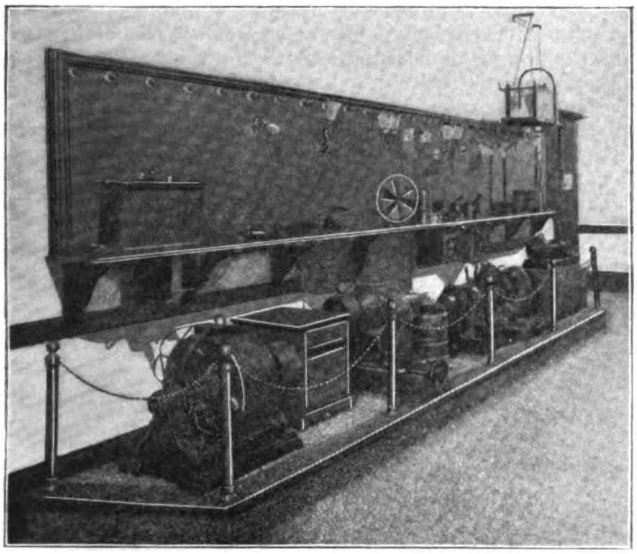
WORTHINGTON CONDENSER AND PUMPS, FIRST DISTRICT STATION.

The auxiliaries for this station are operated by steam, and the oil and air system is similar to that installed in the Union Station described later.

With the intention in the near future of shutting down this plant sixteen hours a day, there is installed in the engine room a rotary transformer unit, shown on page 3, consisting of three 140 k. w. General Electric static transformers and two 200 k. w. rotary transformers, with induction regulators, etc., all built by the General Electric Co.

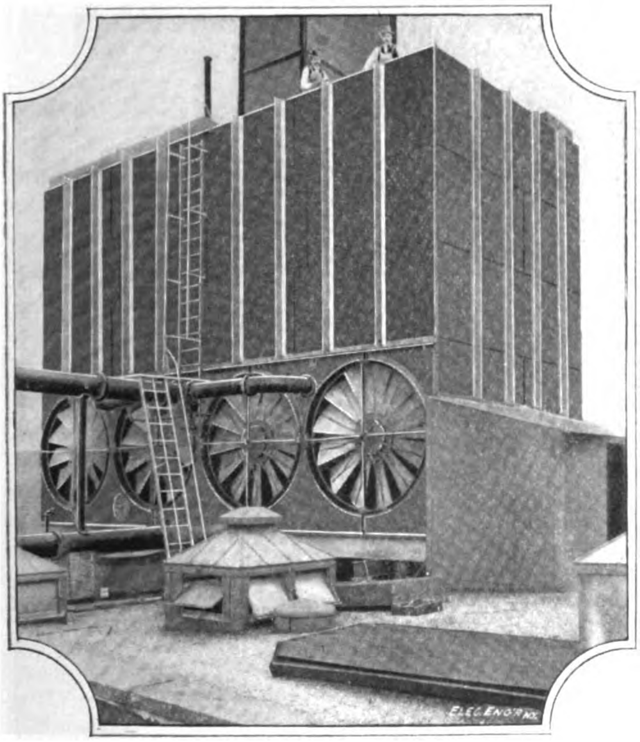
The high tension switchboard consists of a large panel of blue Vermont marble, containing 6,000 volt quick-break switches, mounted on corrugated rubber stands, 6,000-volt wattmeters, fuses, etc.

The low tension switchboard, which is the main switch-



EXHIBITION ROOM IN FIRST DISTRICT STATION.

board of the plant, is of black enameled Vermont slate, 54 feet long and 10 feet high, and as shown on page 4, occupies the whole length of the gallery. The generator panels and rotary panels are placed in the center, and the feeder panels on each side. On the machine panels are switches and instruments for six three-wire units, two boosters, tie lines, rotary transformers, etc. The duplex ammeter and voltmeter instruments are



WORTHINGTON WATER COOLING TOWER, FIRST DIST. STA.

of the Weston type, and Weston-Van Vleck edgewise voltmeters are used throughout. All feeder ammeters are arranged on the duplex system, the meters for the positive and negative side of the system being in the same case. The capacity of the switchboard is 5,000 k. w. at 125 volts.

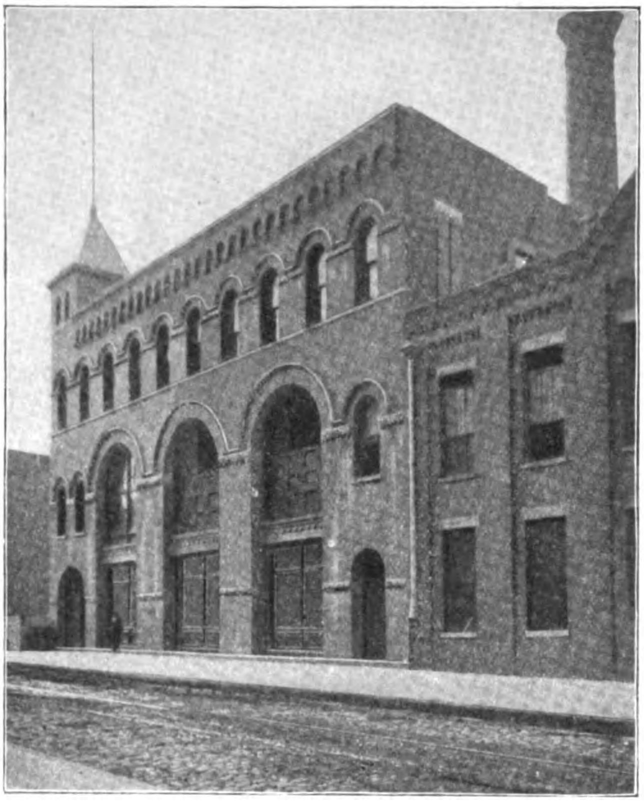
A 15-ton electric crane, built by the Morgan Engineering Company, spans the engine room, and enables any part of the equipment to be quickly and economically handled.

A large booster, built by the C & C Electric Co., in connection with the low tension tie lines enables this station to help out neighboring districts with low tension current in case of necessity. This station is now supplied by duplicate high tension, three-phase, alternating underground feeders from sub-station "A," as a distributing center, as described below.

SUB-STATION "A."

This station, formerly occupied by the steam plant of the Citizens' Electric Illuminating Co., situated at the corner of DeKalb avenue and Navy streets, forms the high tension distributing center for the main supply to the former steam plants of the Edison and Citizens' companies in the city of Brooklyn proper.

The original steam station at this point was made up of two buildings, one the original Thomson-Houston plant of the



SUB-STATION "A," BROOKLYN EDISON CO.

Citizens' Company and the other a fireproof structure, built to take care of the increased business. In the remodeling of this plant into an electrical transformer sub-station, only the new building has been occupied, and not the whole of this was necessary for transformer apparatus.

The former steam equipment of this station consisted of three 400 h. p. Wright-Corliss engines, two McIntosh-Seymour vertical triple expansion engines of 400 h. p., and one Hamilton-Corliss twin compound 1,200 h. p. engine. These engines were belted by means of countershafting to twenty 120-light, 1,200 c. p. Brush generators, furnishing current to the city street arc lighting system. This plant, with its complement of boilers, pumps, piping, heaters, etc., was entirely replaced, while in constant operation, by transformer units, necessary to convert the three-phase alternating current into current for series arc lighting.

The building, as it now stands, complete as a sub-station, consists of a fireproof structure, three stories in height, 75 feet front by 100 feet deep. The lower floor, located below the street level, and with an 18-foot head room, is divided into two rooms, one 45x90 feet, and the other 24x90 feet. In the former room are located the high tension and low tension transformer devices, with their switchboards, etc., while in the latter has been installed a large storage battery plant. Immediately above these rooms are the store rooms of the company, the incan-

descent lamp storeroom being about 20 feet square, with 12-foot ceiling, and the general storeroom 75x100 feet, with 12-foot ceiling. On the third floor are located the trimmers' quarters, arc lamp and meter repair rooms, and the inspection department.

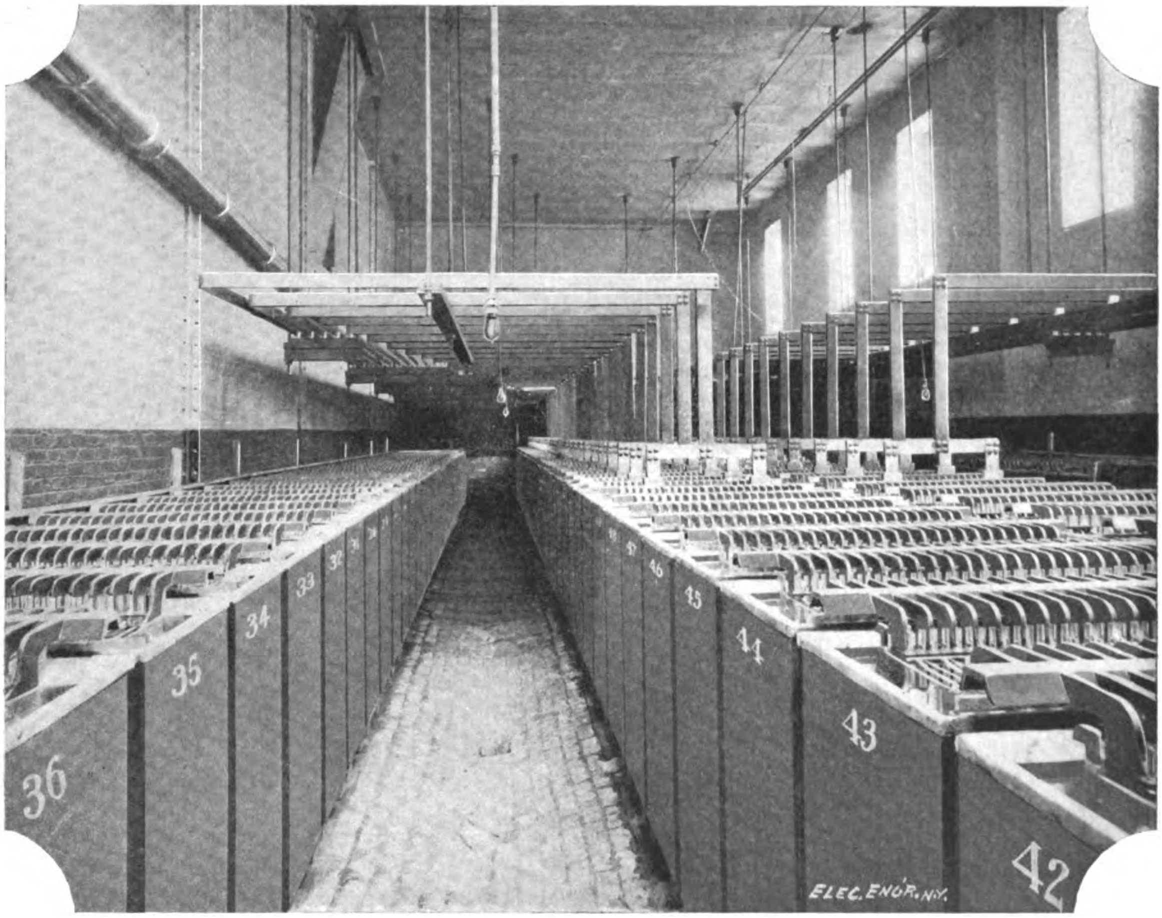
The transformer room on the first floor, as above mentioned, contains the static and rotary converters and the transforming units for taking care of the high tension series arc business of the city street lighting system.

Each of the arc units consists of a General Electric 100 k. w., three-phase, 6,000-volt, synchronous motor, directly connected on either end by flexible insulated coupling to two 120-light, 1,200 c. p. Brush generators (formerly used). This equipment is mounted on a heavy yellow pine base frame, suitably provided for keeping the three shafts in proper alignment. There are at present installed six of these units, of 240-light capacity each, the remainder of the arc lighting equipment being driven by low tension motors, supplied by a General Electric rotary transformer, used also for supplying current to the Edison low tension motors with additional high tension synchronous tion. It is the intention of the company to replace the low tension motors with additional high tension synchronous motor equipments at a later date.

The plant further contains a large 14,000 ampere hour, storage battery with a Churchward booster built by the Excelsior Electric Co., charged from the rotary transformers, above mentioned, and connected to the network of the Edison low tension underground system.

The high tension distributing switchboard, located in this station, and which receives the current from the Union Station, and distributes it, not only to this plant, but to the three Edison stations mentioned below, is located in a special fireproof vault, and is composed of blue Vermont marble, upon which are mounted quick-break switches of G. E. type, set on corrugated rubber projections and supported by barriers. These switches are not designed to be opened with load on, as it will never at any time be necessary to operate them under this condition.

The sub-station switchboard is about 40 feet long by 10 feet high, and is divided into three sections. The central portion of the board is of blue Vermont marble, equipped with quick-break switches, mounted on corrugated rubber stands with barriers, and high tension wattmeters. This portion of the switchboard is designed for the purpose of receiving from the distributing switchboard, located in the vault mentioned above, the three-phase current at 6,000 volts, necessary to take care of the transformer devices of this sub-station. On the right of this section are located the synchronous motor panels for supplying the three-phase current to the motor units, as above mentioned, and on the left a direct current rotary panel, suitable for supplying the three-phase current to static transformers for use with the rotaries. On the extreme right of the board are placed the high tension arc distributing panels, and on the extreme left, panels for receiving the direct current from the rotaries charging the battery and delivering current from the battery to the Edison system, as above mentioned.



STORAGE BATTERY IN SUB-STATION "A." BROOKLYN EDISON ILLUMINATING CO.

The rotary transformer equipment referred to consists of three 140 k. w. General Electric static transformers, receiving the three-phase current at 6,000 volts, and delivering it to the rotaries through induction regulators at 83 volts. The rotary transformers are two in number, each of 200 k. w. capacity, receiving the 83-volt alternating current and delivering 125 volts direct current on the three-wire system to the storage battery and the Edison underground system in the surrounding district.

The storage battery installed by the Electric Storage Battery Co., is located in the room directly in the rear of the sub-station switchboard, and adjoining the large transformer room. It consists of 156 cells, so arranged as to supply, by means of end cell regulating switches, current at two voltages at the same time on a three-wire system. This battery, illustrated on this page, is designed and connected to act as a safeguard to all other systems in case of accident to the main station,

and is capable of taking care of the entire business of the district, including the high tension series system, for a period of two hours, thus giving ample time for the starting of the two reserve stations mentioned below.

By means of the rotary and static transformers connected to the storage battery, 6,000 volts, three-phase current can be delivered from the battery to the synchronous motors running the arc machines at one pressure, while with the other pressure current can be supplied to the Edison low tension system of the surrounding district.

SECOND DISTRICT STATION.

This station, which is situated on Lexington avenue, between Grand and Classon avenues, conected by duplicate underground feeders with the high tension distributing center of substation "A," described above, is one of the original Edison stations, and up to within a short time was operated as a steam station. The building is 60x100 feet, one-story in height and with iron truss roof.

The equipment of this plant consisted, previous to the starting of the three-phase system, of two 250 h. p. Erie-Ball high speed, twin compound, condensing engines, belted each to two 100 k. w. Edison bi-polar, 125-volt generators. Also two 250 h. p. Erie-Ball high speed, twin compound, condensing engines, each belted to one 180 k. w. two-phase Stanley alternator, delivering 2,400 volts at 66 cycles. One of these Stanley alternators is shown on page 9. The above engines are supplied from three 300 h. p. Morrin "Climax" boilers, and the con-

densing is accomplished by a Worthington self-cooling jet condenser with a cooling tower.

There is also installed in the same building a 7,500-ampere hour storage battery plant, illustrated on this page, consisting of 160 cells, and provided with four 30-point end cell switches, so arranged as to provide for a discharge at two different voltages at the same time. This battery was installed by the Electric Storage Battery Co.

The direct current switchboard, of black enameled Vermont slate, is 23 feet long, and contains the switches and Weston round type instruments for the generators and feeders of the station. This board also contains the small switches for controlling the motors operating the end cell battery switches, and also the battery instruments. The capacity of this board, including the battery, is 1,200 k. w. at 125 volts.

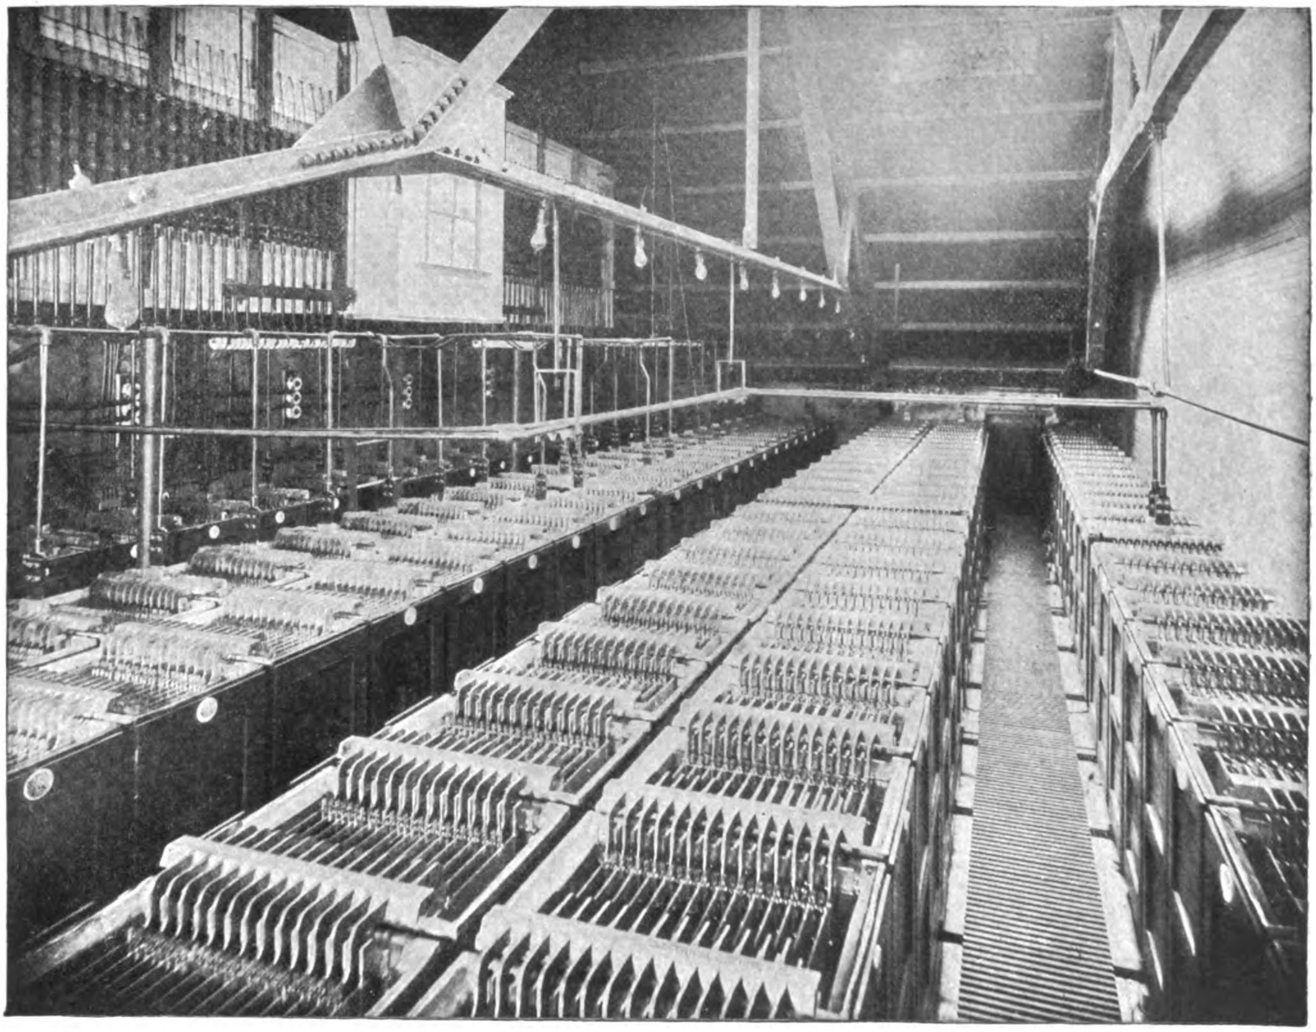
The two-phase alternating current switchboard is of blue Tennessee marble, 21 feet in length, and is equipped with synchronizing devices, five feeder panels, machine panels, etc. Each machine panel has two 2,400-volt, double pole, double throw, Stanley switches, located on the rear of the board, and worked from the front by rack and pinion. Each machine panel has two Whitney ammeters, two Weston voltmeters, two Weston wattmeters, field switch, rheostats, synchronizing lamps, etc. The two-phase feeders leaving the station are provided with Stillwell regulators.

This station, as above described, is now being entirely replaced by transformer apparatus, necessary to transform the three-phase current from the Union Station into low tension current for the Edison three-wire system of the surrounding district, and two-phase, 60-cycle, 2,400-volt current to maintain the alternating distributing system.

Frequency Changers.—The object accomplished by these devices, to be installed in this station, is the conversion of current of low frequency into current of high frequency. The alternating current, as generated in the main station, has a frequency of 25 cycles per second, which is rather too low for incandescent lighting as used in Brooklyn.

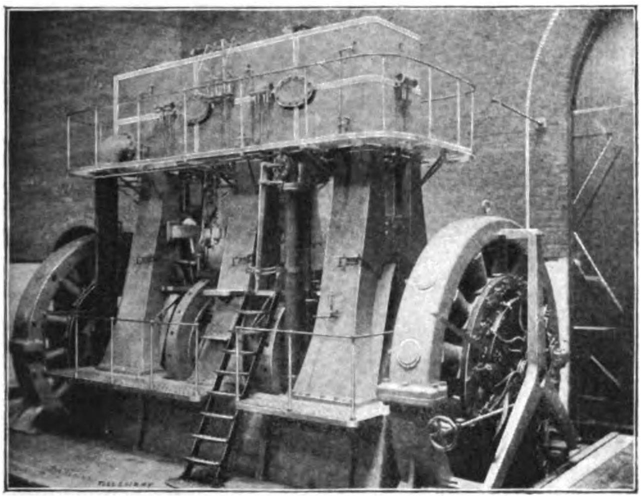
The frequency changer, shown on page 9, consists of a generator similar in general construction to the ordinary induction motor. This generator is directly coupled to a synchronous motor, by which it is driven. The low frequency alternating circuit is connected to the stationary part of this induction generator. The high frequency circuit, supplied by it, is connected to the revolving part through collector rings and brushes. When the primary or stationary part is connected to the circuit the tendency of the machine would be to revolve as an induction motor in a certain direction. This tendency is overcome by the synchronous motor which forces it to revolve in a direction opposite to that of its inclination. If the induction generator stood still when connected to the low frequency circuit it would act as a stationary transformer, and 25-cycle currents would be generated in its secondary. When, however, it is driven by the synchronous motor in a direction contrary to that of its inclination, the frequency of alternation of flux in the secondary is increased, and the frequency of currents there generated is consequently raised.

In the present case the frequency is raised from 25 cycles to 60 cycles. When the set is in operation, the power delivered to the high frequency secondary is derived from two sources, part being taken directly from the low frequency circuit and transformed in the induction generator, the remainder being delivered in mechanical form by the synchronous motor. The rated output of each of these sets is 200 k. w. The size of the motor and generator used in each is practically half that which would be required if a motor-generator set of the ordinary type be used.



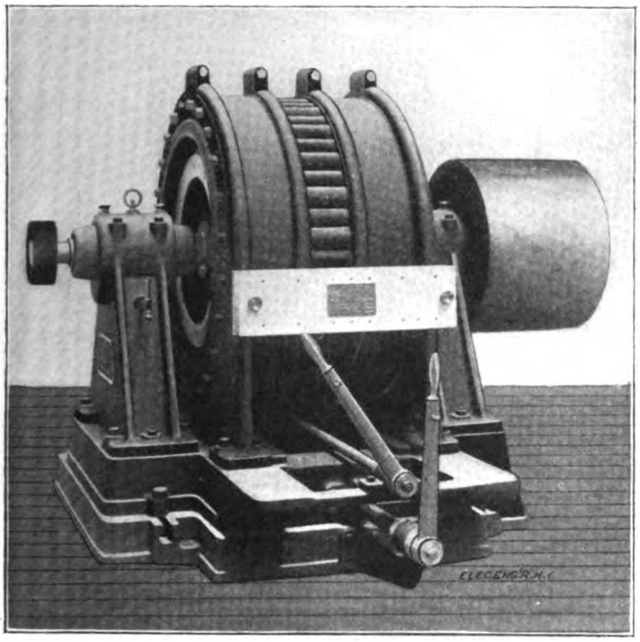
STORAGE BATTERY IN SECOND DISTRICT STATION, BROOKLYN EDISON ILLUMINATING CO.

The losses of the transformation are proportionately less than they would be in an equivalent motor-generator set. The alternating power is delivered to the induction generator from transformers, and the alternating power delivered to the synchronous motors directly from the high tension lines, this motor being similar to those used elsewhere for operating pairs of arc dynamos.



TRIPLE EXPANSION DIRECT CONNECTED UNIT, 3D DIST. STA.
(William Tod & Co., Engine and General Electric Generators.)

The direct current transforming apparatus consists of three 140 k. w. General Electric static transformers, which take the current from the high tension distributing center (sub-station "A") over two miles of underground conductors, at 6,000 volts, delivering it to the rotaries, through the induction regulators, at 83 volts. These rotaries, two in number, and each of 200 k. w. capacity, take the current at 83 volts alternating and deliver it to the three-wire system at 125 volts, three-wire, direct current.



STANLEY 180 K. W. TWO-PHASE GENERATOR IN 2ND DISTRICT STATION.

There will shortly be in operation at this station the General Electric "phase voltage alternation" transformer to replace the two-phase machines. This transformer takes the three-phase, 6,000-volt, 25-cycle, alternating current of the main station and transforms it into two-phase, 2,400-volt, 60-cycle, alternating current for the two-phase distributing system. When this apparatus is in place (which will be about March 1) the entire steam plant in this station will be dispensed with, the station operating continuously as a transformer sub-station.

THIRD DISTRICT STATION.

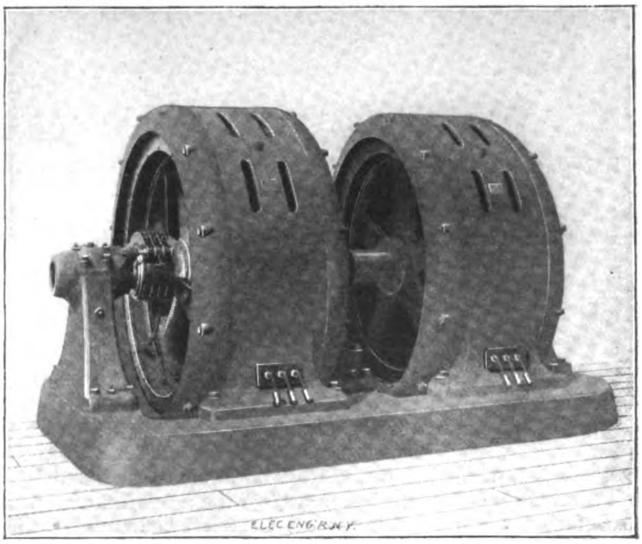
The Third District station, situated on Gwinnett streeet, within a few rods of Marcy avenue, is connected to the high tension distributing center (sub-station "A") by underground feeders, two miles in length. This station, erected by the company in 1892, covers an area of 70x120 feet, and 40 feet in height, this one story being covered by an iron truss roof. It is divided transversely into two rooms, one 45x70 feet, and the other 55x70 feet. The former contains three vertical Morrin boilers, two of 250 h. p. each, and one of 600 h. p.

The engine room contains two 750 h. p. vertical, triple expansion, condensing, Williams engines, one built by the Lake Erie Engineering Works and the other by William Tod & Co. Each engine is directly connected to two 200 k. w. Edison multipolar generators, 125 volts. The water for condensing is furnished by driven wells, a Conover vertical air pump condenser and a Dean jet condenser being used. One of the 750 h. p. engines is directly connected to its own independent air pump in conjunction with a jet condenser.

The switchboard is 20 feet in length by 10 feet in height, of black enameled Vermont slate, and contains the low tension switches, Weston ammeters, voltmeters, etc.

A G. E. booster supplies current to a tie line connecting this station with the Second District station, which in turn, as before described, is connected to the First District station, thus enabling the three stations to exchange low tension current in case of necessity.

For the purpose of shutting down this station 16 hours a day, there is installed a transformer unit, similar to that installed in the First District, consisting of three 140 k. w. General Electric static transformers, two 200 k. w. rotary transformers, with induction regulators, etc.

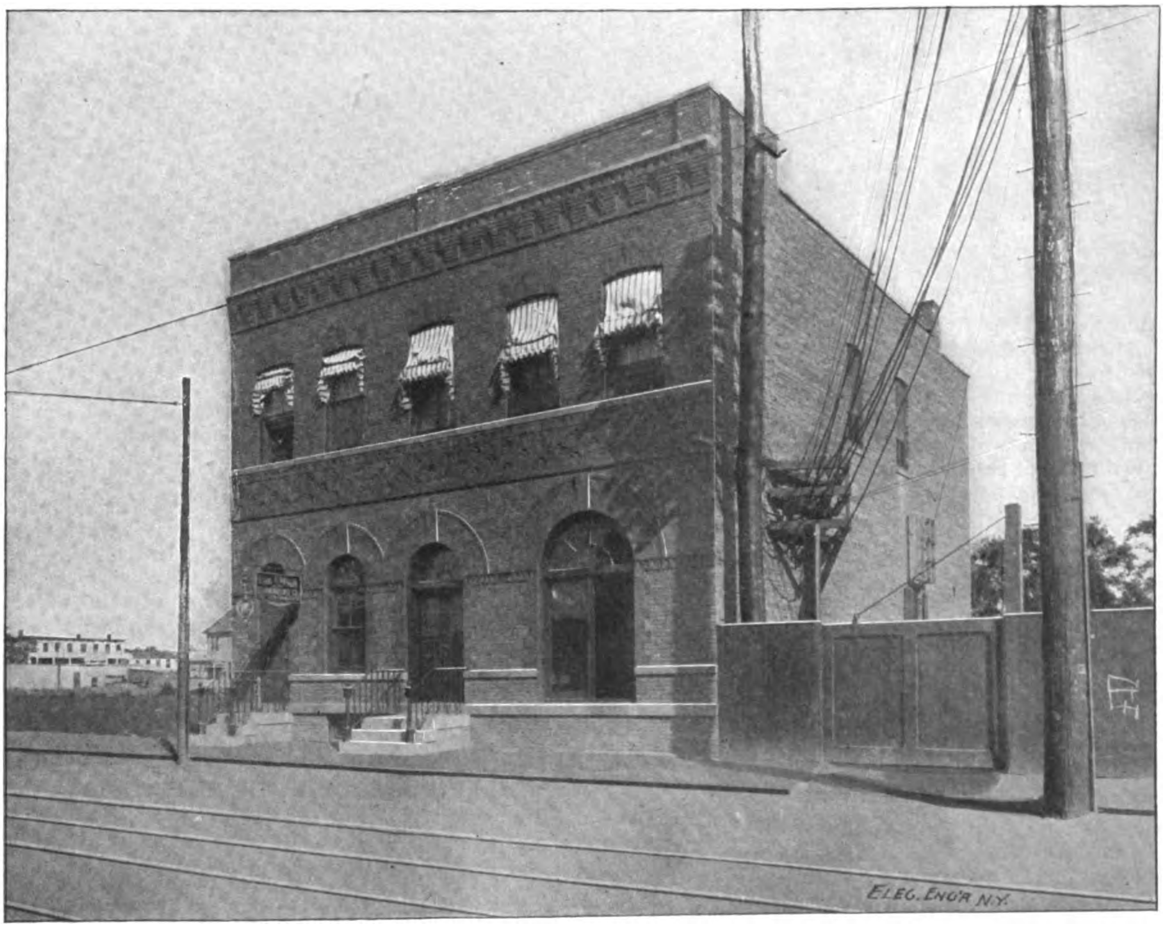


FREQUENCY CHANGER, SUB-STATION E.

SUB-STATIONS "B," "C" AND "D."

Sub-station "B" is located at Bergen Beach, nine miles from the Union Station. It is connected with the Second District station, a distance of eight miles, by overhead feeders. The building consists of a small frame structure 18 feet square, containing the phase and static transformers for reducing the two-phase, 2,400-volt, 66-cycle, current into low tension alternating current for distribution. It is the purpose in the near future to build a more substantial station, connecting it with the main Union Station, and to install the necessary phase and frequency changers. This station is shown on page 9.

Sub-station "C" is similar in character to sub-station "B," and is not yet of a permanent character, as both these sub-stations are in operation but to a very small part of their capacity except during the summer months.



EXTERIOR OF SUB-STATION "E," AT CONEY ISLAND, BROOKLYN EDISON ILLUMINATING CO.

Sub-station "D," designed for the East New York section of the city, has not yet been constructed, the district being at present supplied with two-phase alternating current from the Second District station. In this sub-station will be placed step-up transformers, raising the pressure from 6,000 to 12,000 volts for transmission to the Long Island system.

SUB-STATION "E."

The district occupied by this station is one of the many suburban watering places surrounding Brooklyn proper. Coney Island, known throughout the world for its entertainment facilities ,and for its "Bowery," is in full blast from May 1 to October 1, during which time no expense is spared by its inhabitants for lighting, etc., to attract the attention of visitors. The station is located close to the electrical center of distribution, and is modern in all respects.

The building, a view of which is given on this page, is of brick, quite ornamental in character, having a frontage of 40 feet and a depth of 50 feet. The upper, or second story, is divided into two apartments, occupied by the employés (and families) who take care of the station. These living apartments are independent of and entirely cut off from the remainder of the building, having a separate vestibuled entrance and also a private cellar for storage.

The first floor is divided into office and transformer room, the latter entering through the former, which has entrance direct to the street. The plans and sectional views on page 12, illustrate the arrangement of this novel type of sub-station.

The transformer room covers a space of 1,500 square feet, and provides for transformers of a total capacity of 1,000 k. w. All conductors enter and leave the building overhead. The incoming conductors, six miles in length, from the Union Station, supply three-phase current at 6,000 volts, 25 cycles, and the outgoing supply (1) low tension direct current, 115 volts, three-wire system; (2) high tension current for series arc lighting; and (3) two-phase, 2,400-volt, 60-cycle, for local suburban distribution. No lightning arresters are used on the overhead circuits other than two barbed wires run on the top of the cross-arm of the poles and grounded at frequent intervals.

The transformer equipment of this station, all of the General Electric type, consists of six 140 k. w. static transformers, which supply 83 volts alternating three-phase current to six 100 k. w. rotary transformers for the low tension Edison three-wire system, and a 200 k. w. phase-voltage alternation transformer to supply the 2,400-volt, two-phase, 60-cycle, distributing system for use beyond a radius of one mile. In conjunction with the rotary transformers are the standard induction regulators, etc. There are also installed synchronous motor arc generator units, such as described in connection with sub-station "A," for the conversion of the three-phase, 6,000-volt, 25-cycle, alternating current into the direct current for series lighting. Such a synchronous motor unit driving a Brush 120-arc light machine (by belt temporarily) is shown in the foreground in the engraving on page 11.

The switchboard, 30 feet in length, is divided into three sections. The center portion of the board, of blue Vermont marble, is equipped with quick-break switches, mounted on corrugated rubber stands, so arranged as to distribute the 6,000-volt,

three-phase current, either to the static transformers or to the synchronous motors. On the left is placed the low tension switchboard, of black enameled Vermont slate, containing the low tension switches, feeder switches, Weston voltmeters, ammeters, etc. On the right of the switchboard, on Vermont marble, is placed the series arc distributing switchboard, and also the two-phase distributing switchboard. Each portion of the switchboard is furnished with recording wattmeters, so that the use of the current for the different purposes can be readily ascertained.

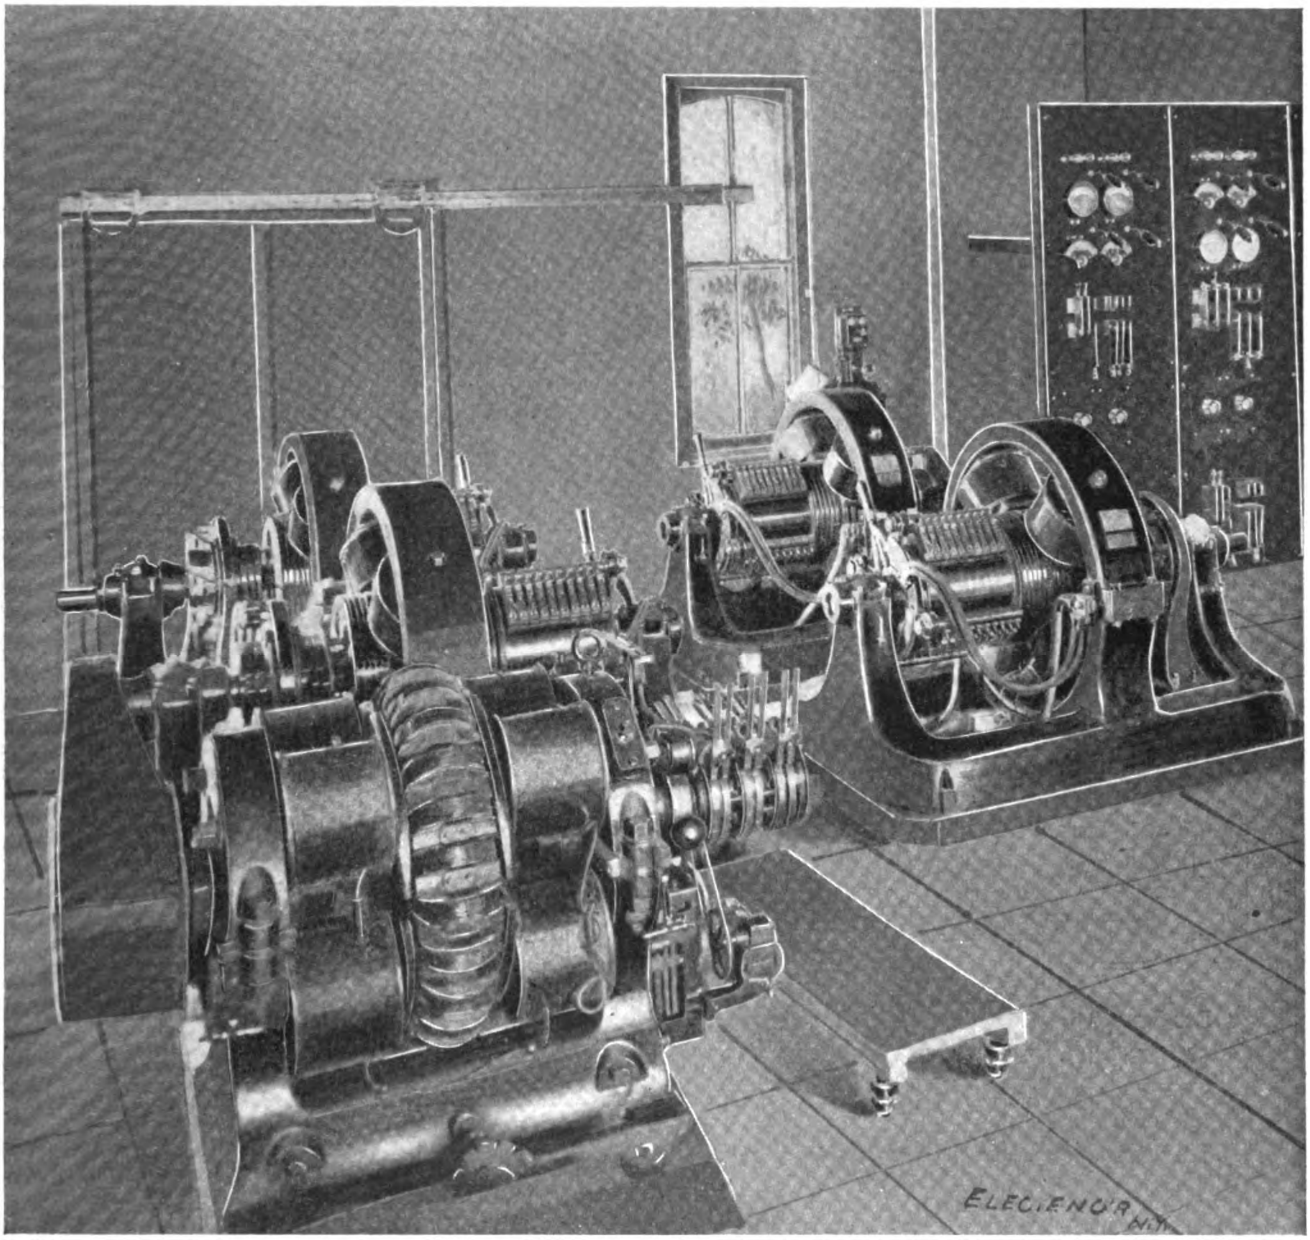
SUB-STATION "F."

This sub-station, situated on Carroll street, is unique in general appearance and design. The district in the center of which it is located is occupied by handsome, private residences, apartment houses and churches, and is what might be termed a strictly residential territory.

In the heart of such a district the company purchased a small frame house, which had been occupied for the past twenty years. The external appearance of the building, shown on page 13, was left undisturbed. The interior was remodeled so that the parlor and upper rooms were made into one large room, in which are installed four 100 k. w. rotary transformers. The extension to the house, formerly the kitchen (the stove is still in place, as seen in the engraving on page 13, became the switchboard room, while a small brick fireproof building in the rear contains the 140 k. w. static transformers and regulators, all of the General Electric type. All current enters the building underground at three-phase, 6,000 volts, and also leaves, underground on the direct current, 115 volts, three-wire system. So carefully have all details been arranged that no one passing along the street or entering the courtyard sees or hears anything which would lead him to suppose that the building was not occupied as a residence.

The station is attended to by one person on a watch, who has no trouble in taking care of the load of 2,000 amperes.

The high tension switchboard of this station, of blue Vermont marble, is located in a fireproof brick building in the rear of the house. The low tension switchboard is of black Vermont marble, and is located in the former kitchen of the house. It is equipped with low tension feeder switches, rotary transformer switches, ammeters, voltmeters, recording wattmeters, etc., so as to enable the current delivered by the station to be closely ascertained. The plan and sectional views on page 12 show the arrangement of this unique little plant.



GENERAL ELECTRIC ROTARY TRANSFORMERS AND BRUSH ARC DYNAMOS, SUB-STATION "E," CONEY ISLAND.

RECAPITULATION OF GENERATING SYSTEM.

In order to give out readers some idea of the present state of the generating and sub-station system of the Brooklyn Edison Co., as embodied in the stations just described, we give

below a classified digest of the various types of apparatus employed. This does not include the new Union Station.

TYPES OF APPARATUS EMPLOYED.

Class A.—Vertical engines directly connected to low tension direct current multipolar generators, three-wire system, with corresponding boiler equipment.

Class B.—Static and rotary converters and induction regulators to transform 6,000 volts, three-phase, 25 cycles, alternating into low tension direct current, three-wire system.

Class C.—Synchronous motor arc generator to transform 6,000 volts, three-phase, 25 cycles, alternating, into from 2,000 to 6,500-volt direct current for series arc circuits.

Class D.—Static transformers, synchronous and induction motor, to transform 6,000 volts, three-phase, 25 cycles, alternating, into 2,400 volts, two-phase, 60 cycles, alternating.

Class E.—Storage battery for low tension three-wire system.

Class F.—Static transformers, two-phase, 2,400 volts, 60 cycles, to 115 volts alternating.

The following table indicates the stations or sub-stations in which these various types of apparatus above enumerated are employed, and the amount of power in kilowatts represented by each type:

EDISON FIRST DISTRICT.

2,800 k. w. .... Class "A"
400 k. w. .... Class "B"

EDISON SECOND DISTRICT.

CONSIDERATIONS DETERMINING THE CONSTRUCTION OF THE UNION STATION.

With this necessarily brief review of the Brooklyn Edison Co.'s original plant and its gradual accretions we come to the consideration of its latest and highest development in station construction, the Union Station, at 66th street, Bay Ridge. But before entering into the details of this truly magnificent undertaking it will prove instructive, we believe, to trace the steps and conditions which finally led up to it.

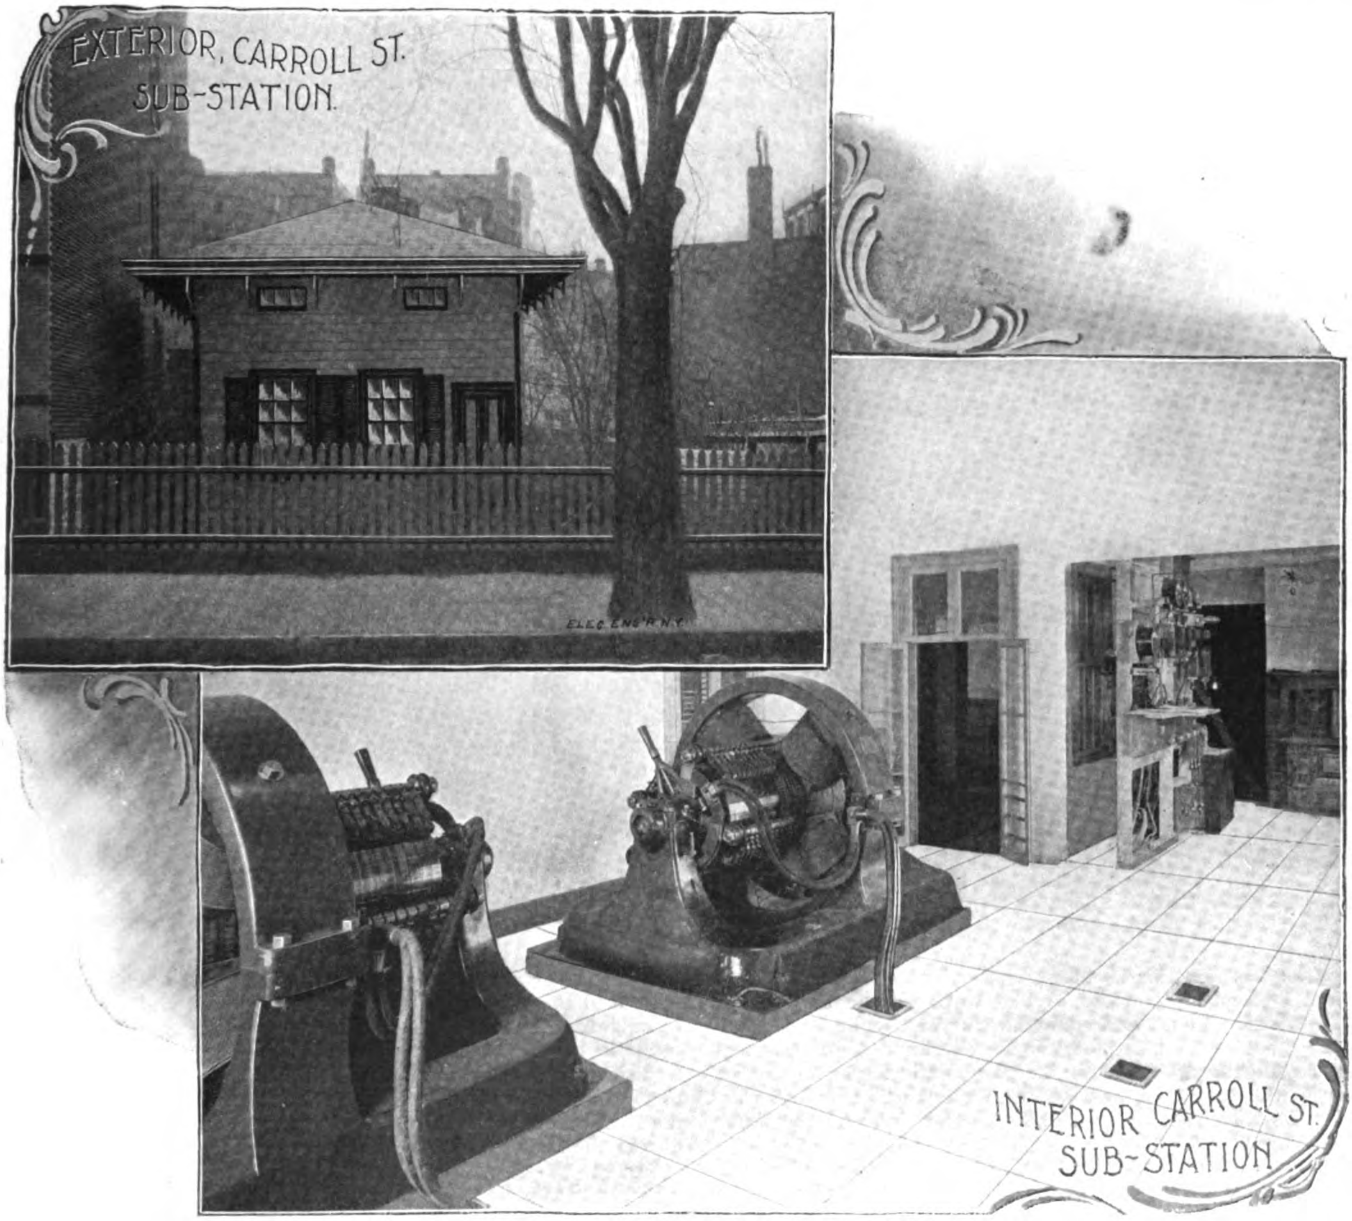
The purchase of the Citizens' Electric Illuminating Co., of Brooklyn, by the Edison Electric Illuminating Co., of Brooklyn, it may be recalled, was made during the early part of 1895, the Edison Company taking actual possession of the stations of the Citizens' Company on July 1 of that year. After making alterations and additions to the Citizens' stations, whereby increased business could be taken care of, attention was given to increasing the economy of the two companies by operating them in conjunction.

The Edison Company was at this time operating under an exclusive underground franchise, a three-wire, 115-volt system, and the Citizens' Company operating under an overhead franchise a high tension, series arc system from 120-light (1,200 c. p.) Brush machines and a 2,400-volt, two-phase, 60-cycle alternating system. At the same time questions were constantly arising as to the means of extension into new districts, so that the problem became quite complicated.

General Superintendent Barstow, of the Edison Company, appreciated the fact that the highest economy could be obtained only when all the systems of the two companies were operated from a common source, and accordingly began working on laying out a high tension transmission system. The plans were finally submitted to the officers of the company on September 1, 1896, and were in turn presented to the directors of the company on November 2.

The plan, as outlined in the report, consisted of the erection and operation of a high tension alternating station, located on the water front, in which the loads of the various stations and systems could be consolidated on one set of generators. From this plant, underground feeders carrying the alternating current at a pressure of 6,600 volts, were to extend to all the present stations of the two companies, the current being brought from the water front station to the center of the city and there distributed. The low tension, three-wire, generating apparatus in the various stations was to be replaced with static transformers, reducing the current from high to low voltage alternating, and by means of rotary transformers furnishing direct current.

The high tension series apparatus was to be replaced by high tension synchronous motors, either end of which direct con-



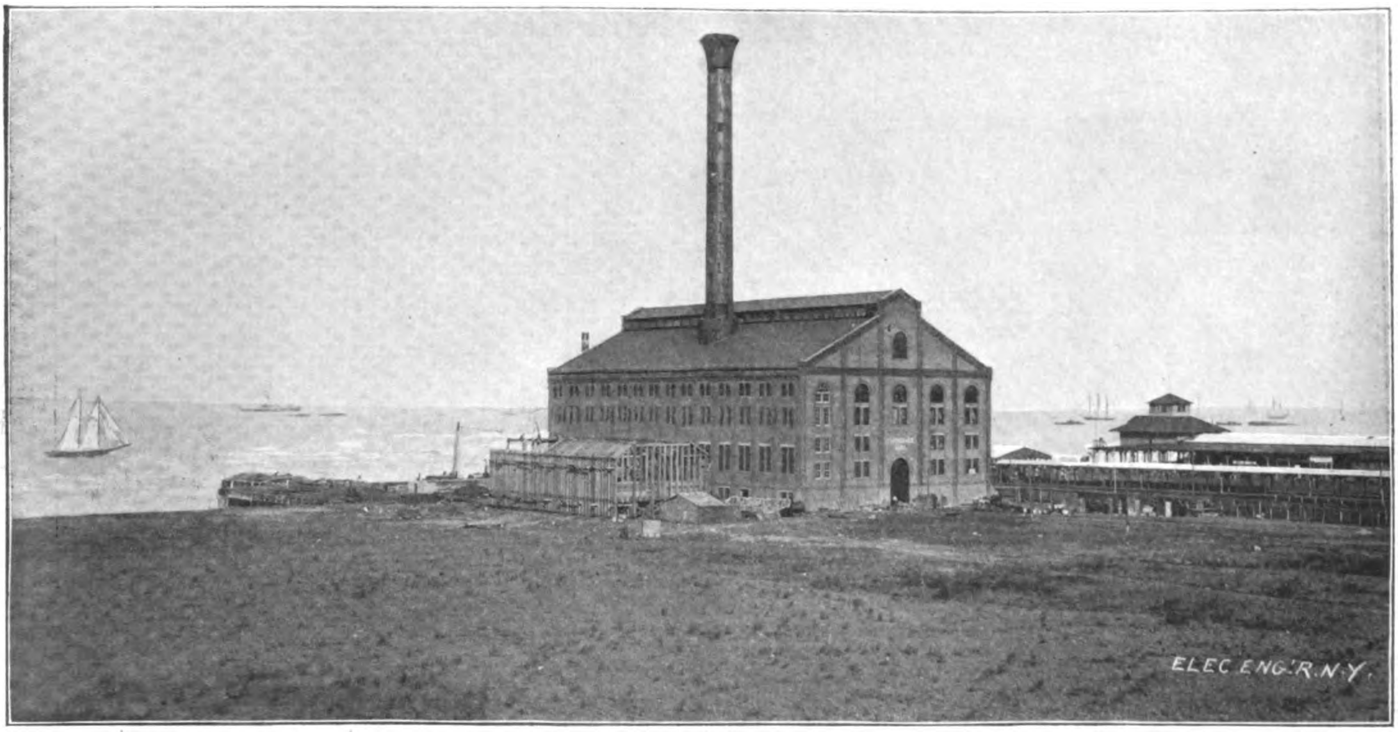
nected to a 120-light series arc generator. The two-phase alternating apparatus was to be replaced by phase alternation transforming apparatus, which at the same time would reduce the voltage.

The alternating current selected, after carefully going into the matter, was three-phase at 25 cycles and 6,600 volts. Current at this pressure was to be taken direct from the large generators and delivered to the static transformers in the substations at 6,000 volts, which in turn were to deliver it to the rotaries at 83 volts alternating pressure, and this in turn delivered to the system at 125 volts continuous current. This primary current also was to enter direct the synchronous motors, directly connected to arc machines, and also apparatus whereby the three-phase, 6,000 volts, 25 cycles, was transformed into two-phase, 2,400 volts, 60 cycles, for secondary lighting.

With such a comprehensive system it was shown to be possible not only to shut down all the present stations of the Edison and Citizens' companies, but also to establish in the substations receiving current, good distribution in any form of current desired. The economies effected by such a system were great, in fact, so favorable did the proposition appear that

number of sub and semi-generating stations to be supplied from the new plant nine in number, the standard type for the future being that designated as sub-station "E," described above.

Upon the acceptance of this plan, property was purchased at the foot of 65th street, Bay Ridge, opposite Staten Island, on the line of the Long Island Railroad, having a frontage on New York Bay of 260 feet, and a depth of 500 feet. Upon this property was planned the erection of a station of 60,000 h. p., ultimate capacity, the erection of one-quarter of which was begun at once. Work was commenced simultaneously on this main generating station, three new sub-stations and on the changing of the four steam stations. On May 15 it was found that, all the underground work having been completed, as well as sub-station "E," it would be possible to start the system in a small way by stepping up from the low tension bus of the First District Edison station and transmitting the 6,600 volts thus obtained twelve miles to sub-station "E," Coney Island, and there step-down to supply the summer business in this territory. This plan was at once carried out, and on June 1, 600 h. p. were being distributed from this sub-station. This



THE NEW UNION STATION OF THE EDISON ELECTRIC ILLUMINATING CO., OF BROOKLYN, AT BAY RIDGE.
(Long Island Shore of New York Harbor.)

the work was immediately authorized by the directors and was started December 15, 1896. Actual work on the building of the bulkhead, piers and foundations was commenced on March 15, 1897. The economy in the operation of the business of the company as based on the plan outlined above, can be seen by the local diagrams on page 21, which give the load of the individual stations and the combined load on the water front station.

As it was not deemed advisable to shut down all of the steam stations during the first year, provision was made for operating the two largest stations for eight hours a day during the winter months. In order to render the system more reliable and to guard against any interruption to service, which up to this time had been of the best, it was deemed advisable to install in the stations two large storage batteries, which would enable the service of either company to be maintained continuously for three hours, thus giving ample time to provide for increased service.

In addition to taking care of the load of the present stations of the two companies, the plan proposed included the erection of various transformer sub-stations throughout the city, which would contain whatever apparatus was necessary for supplying the immediate surrounding district. The sub-stations authorized at the outset were three in number, making the total

double conversion system was continued throughout the summer until the starting of the Bay Ridge plant, and aided materially in the shifting of the load from one station to the other in order that the new work might progress without interfering with the business of the company. The most difficult part of the undertaking was the shifting over to the new system the entire business of the company, occurring, as it did, during the heavy business season of the year.

UNION STATION.—BUILDING AND FOUNDATIONS.

The great Union Station, as indicated above, is located on the water front, facing New York Harbor, where it looms up as the first great landmark greeting the incoming Atlantic tourist, on the Long Island shore. The building is 206 feet long and 120 feet wide, of composite brick and iron construction. The foundations of the building, consisting of a bed of concrete three feet thick, rest upon 40 ft. piles.

Longitudinally through the center of the building, and underneath the bed of concrete, are built two large tunnels, the masonry resting upon pile foundations. The dimensions of these tunnels are 9 feet 9 inches high by 6 feet 8 inches wide, and at the lowest tide they are flooded with six feet of water. The mouth of each tunnel extends out into New York Bay a distance of 50 feet from the building, and at this point they

are protected by heavy copper wire screens. The purpose of these tunnels is to have water directly under each engine without requiring suction, the condensing apparatus of the engine taking the water from one tunnel, through the surface condenser, and discharging it into the other. This arrangement has somewhat of a siphon effect, reducing to a large extent the energy required for the circulation of the condensing water, and at the same time rendering each engine or section of engine independent.

Upon the concrete foundation, mentioned above, were placed heavy granite pedestal stones, and upon these rest the iron columns supporting the framework of the structure. The brick filling-in walls average about 18 inches in thickness, and on the inside of the building are finished in compressed brick, which is in turn painted. The exterior of the building is finished in common brick, the panels being relieved by the use of washed brick. The roof of the structure is covered with slate on wood, resting on iron framework. Extending the length of the building, and through its center, is a turreted skylight, 20 feet in width, 206 feet in length and about 7 feet high at the ventilators.

The interior of the building is divided longitudinally into two parts by a curtain wall extending from the foundations to the roof, about 90 feet in height by 200 feet in length. The two rooms thus formed are the engine and generator room, about 200x66 feet, and the boiler room, about 198 feet 6 inches x 46 feet 3 inches.

The engine foundations are built to a height of 17 feet above the foundations of the building, at which point is located the engine room floor, leaving a basement for piping, pumps, etc., 16 feet in height. The boiler room floor is placed at a level two feet higher than this, allowing a basement head room of 18 feet, to provide for economizers, etc.

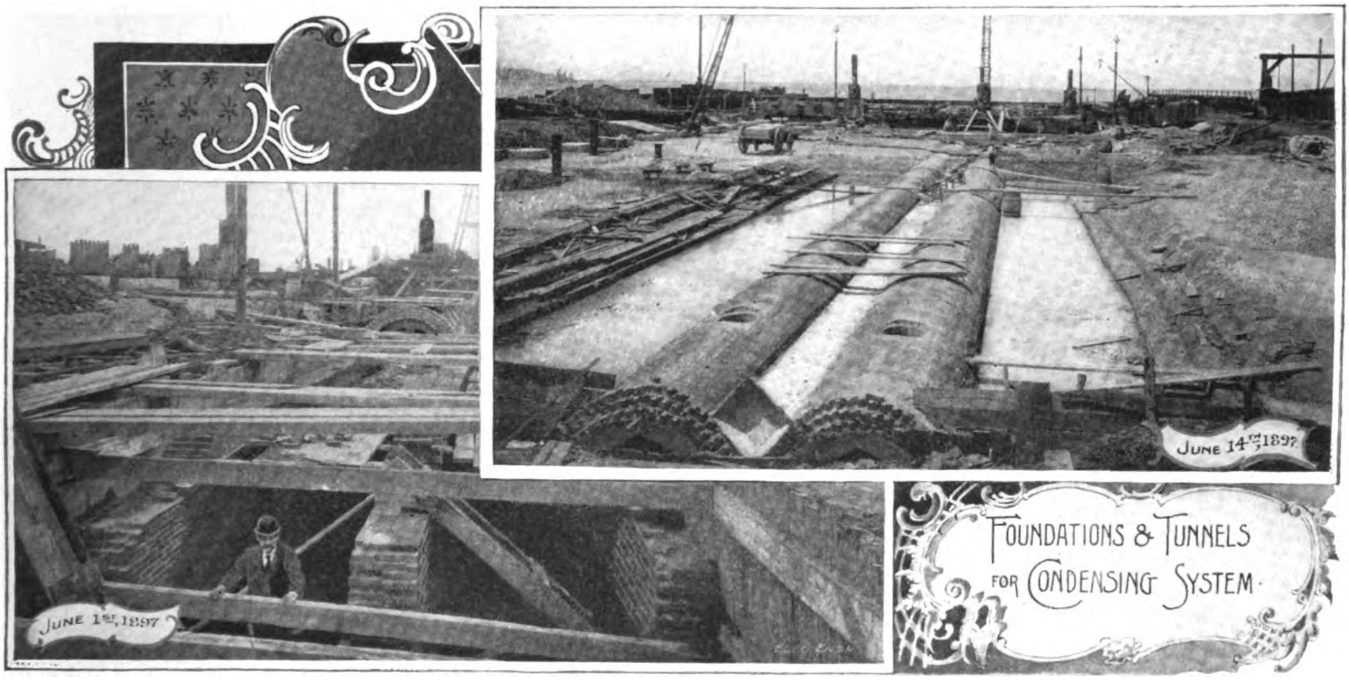
In the center of the boiler room, and against the curtain wall, are located the flues and stack foundation. From the stack foundation, which terminates 17 inches below the boiler room floor level, extends the steel smoke stack.

At the east end of the building, at a height of about 20 feet, above the engine room floor level, is located the switchboard gallery, at either end of which is a small room for the use of the attendants. Directly beneath the switchboard gallery, and on an intermediate floor, is built the high tension testing room and station superintendent's office. Below these, and on a level with the engine room floor, are the tool and toilet rooms. Beneath the engine room floor, and directly below the tool and toilet rooms, is located the high tension cable vault, into which are led all the alternating conductors, and from which they extend to the gallery and the underground conduits.

On the west end of the building, below the engine room floor, are located the wash rooms and shower sprays for the engineers and firemen. A spiral staircase extends from the roof of the electrical gallery to walks located on either side of the ventilator turret, thus enabling the ventilators to be properly handled and the windows to be cleaned. On the west end of the building and on a level with the ventilator walks, is built a large balcony overlooking the harbor.

Extending into the building, through a large door in the east end, is a railway switch from the Long Island Railroad tracks, and traveling longitudinally down the engine room, at a height of about 50 feet from the floor, is a three-motor Shaw electric crane, of 25 tons capacity. This equipment enables the company to deliver machinery into its building on the cars on which it is originally loaded, and to transfer it electrically from these cars to any part of the building for the purposes of erection with the aid of one operator in the crane. This crane, operated during the construction of the building by a temporary transformer station, enabled quick erection to be made, and to its use is largely due the completion of the entire plant in less than eight months.

The contractors on the station building, etc., were the following: John W. Ferguson, foundations and piling. Spearin & Preston, bulkhead and docks. John H. Parker Co., mason work, carpenter work, plumbing and painting. Milliken Bros., iron work. Thomas J. Lawler, smokestack. F. W. Miller, wells. Ansonia Copper Co., copper. W. J. Bolton & Co., trucking and erecting.



Foundations & Tunnels for Condensing System

ENGINES.

The building is laid out to contain 15,000 h. p. of horizontal engines, directly connected to three-phase generators. Provision has been made in the size of the property and the construction of the building for adding, either on the south side or on the east end of the present structure, so that the capacity of the entire plant, when completed, will be 60,000 h. p. Provision has also been made in the height and general arrangement of the building for using vertical instead of horizontal engines and increasing the boiler power, so that the present building capacity can be increased from fifteen to twenty-five thousand horse power, increasing the ultimate capacity of the company's property from sixty to one hundred thousand horse power.

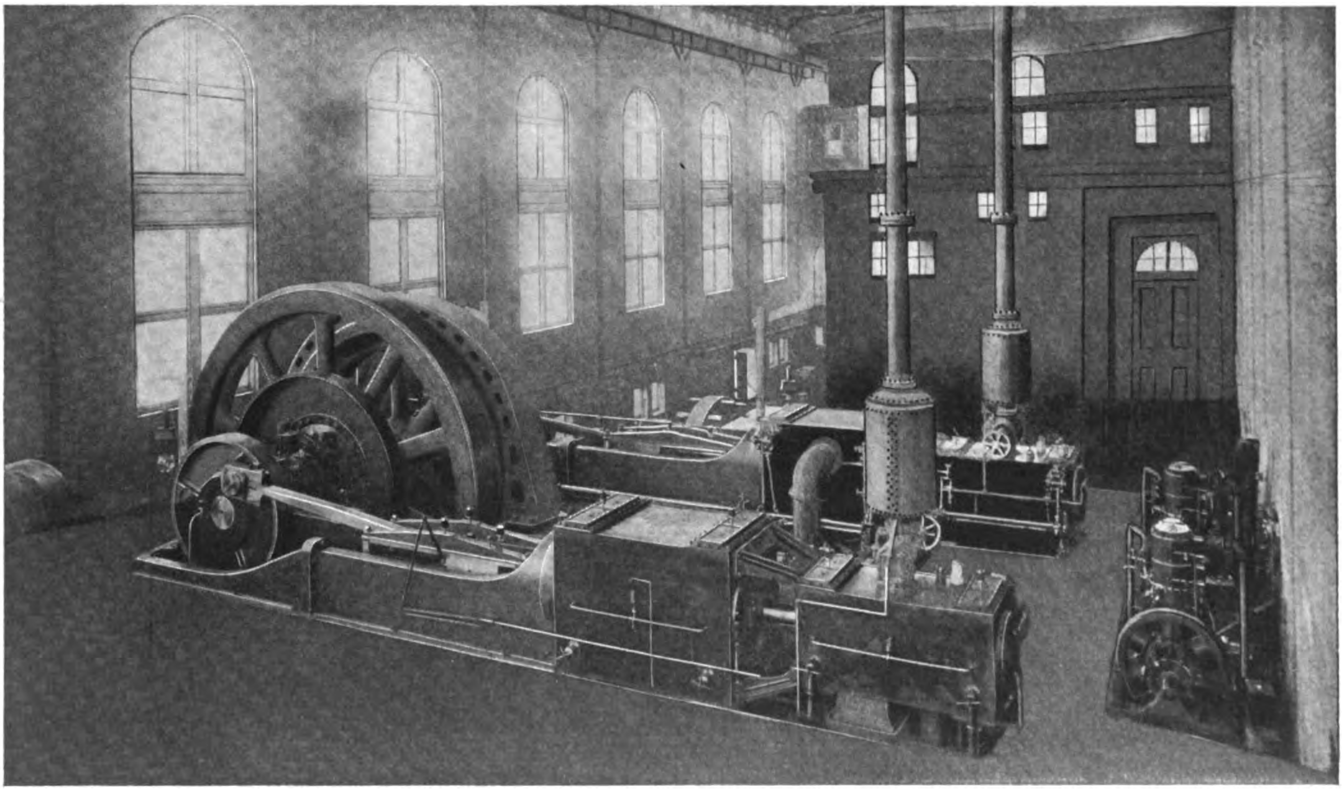
The unit decided upon for the plant was a 3,000 h. p. engine, directly connected to a 2,000 k. w. generator. A 1,500 h. p. Hamilton-Corliss engine, connected to a 1,000 k. w. generator, removed from another plant, is being installed temporarily in addition to the large engine mentioned above. This 3,000 h. p. unit the company will be able to keep fully loaded almost all the time on account of the consolidation of the present loads of its numerous stations and sub-stations.

The 3,000 h. p. engine, built and installed by McIntosh, Sey-

mour & Co., is of the tandem, twin compound horizontal side crank type, each side of the engine being independent of the other, and connected to independent condensing apparatus. The accompanying table gives the size and weights of the different parts of this magnificent engine.

DIMENSIONS AND WEIGHT OF McINTOSH, SEYMOUR 3,000 H. P. DOUBLE COMPOUND HORIZONTAL SIDE CRANK ENGINE.

Diameter of high pressure cylinder, 24 inches.
Diameter of low pressure cylinder, 48 inches.
Stroke, 66 inches.
Revolutions per minute, 75.
Initial steam pressure, 165 pounls, 26 inches vacuum.
Rated load in indicated horse power, 3,108; cut-off, 1/4.
At 6-10 cut-off, corresponding indicated horse power, 5,000; maximum cut-off, 8-10.
Total weight of engine, 605,000 pounds.
Directly behind the McIntosh, Seymour unit are located
Diameter of bearings, 24 inches; length, 42 inches.



DIRECT CONNECTED 3,000 H. P. THREE-PHASE UNIT, UNION STATION, BAY RIDGE.
(General Electric Co. Generator,—McIntosh, Seymour & Co. Engine.)

Diametef of shaft between bearings, 27 inches.
Diameter of crank pins, 13 inches; length, 11 inches.
Diameter of crosshead pins, 11½ inches; length, 11 inches.
Bearing surface of crossheads, 19 inches by 38 inches.
Diameter of piston rods, 7½ inches.
Diameter of steam pipes, 9 inches.
Diameter of exhaust pipes, 20 inches each.

This engine was designed and built upon specifications which called for less than one quarter of 1 per cent. variation in angular velocity, and this was deemed an advisable requirement in connection with the operation of rotary transformers, etc.

The generator, which is directly connected to this engine, is of the revolving field type and of 2,000 k. w. capacity. In order to enable units of this size to be operated without difficulty in parallel, an auxiliary arrangement was designed by the McIntosh, Seymour & Co., whereby, by the movement of a lever, the speed of the engine can be gradually increased or decreased while running without in any way handling the steam supply.

Directly beneath this engine, in the basement and between the engine cylinders and the tunnels, mentioned before, are located the circulating and air pumps, reheater and condenser, each side of the engine, as stated above, having its independent equipment.

The smaller unit which is being installed from another plant of the company consists of a twin compound, Hamilton-Corliss engine, of 1,500 h. p. capacity, directly connected to a 1,000 k. w. alternating current generator of the revolving field type. The dimensions and weights of this engine are as follows: High pressure cylinders, 26x48 inches; low pressure cylinders, 48x48 inches. Weight of engine without wheel, 160,000 pounds. Wheel, 18 feet diameter, built in sections; weight, 65,000 pounds.

There is also located in the engine room, directly behind the Hamilton-Corliss engine, a 300 h. p. triple expansion vertical, Lake Erie engine, built by the Lake Erie Engineering Works. To this engine is directly connected, to each end of the shaft, a 100 k. w. multipolar, 125-volt, General Electric generator. This combined unit is for use in conjunction with the auxiliaries, as described below.

Directly behind the McIntosh & Seymour unit are located two 50 k. w. General Electric multipolar generators, each with its directly connected compound vertical engine, these units being intended to act as exciters for the large generators.

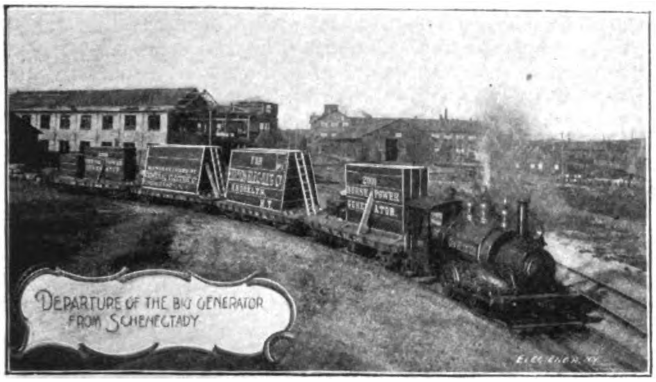
THE BOILERS, STOKERS, ECONOMIZERS, ETC.

The boilers are located with their rears to the curtain wall, this arrangement bringing them as close to the engine cylinders as possible, as shown on the sectional view in the accompanying supplement. The boilers are of the Cahall-Babcock & Wilcox "flowed" steel type, the contractors being Thayer & Co., Inc., of New York, and the builders the Aultman & Taylor Machinery Co., of Mansfield, O.

Each boiler, which is "double decked," has a nominal capacity of 500 h. p., and is made up of 36 sections, expanded into headers of "flowed" steel, each section having six 4-inch tubes, 18 feet long. These various sections are joined to three 36-inch steam drums, the length of the drums being 22 feet 6 inches. These drums are made of O. H. steel, having a tensile strength of 60,000 pounds per square inch of section, 7-16-inch thick, with longitudinal seams; butt strap joints, treble riveted. The boilers are designed to work safely up to 200 pounds pressure.

The boilers are equipped with American end feed, forced

draft stokers, built by the American Stoker Co., of Brooklyn, N. Y., three stokers, independently driven, being installed for each furnace, or six per battery. These stokers consist simply of a trough, or magazine, in the bottom of which a screw or worm is kept revolving by means of a small steam motor requiring 1-5 h. p. to operate. The coal which is fed to a hopper situated in front of the boiler passes into the magazin: end, is



Departure of the big generator from Schenectady

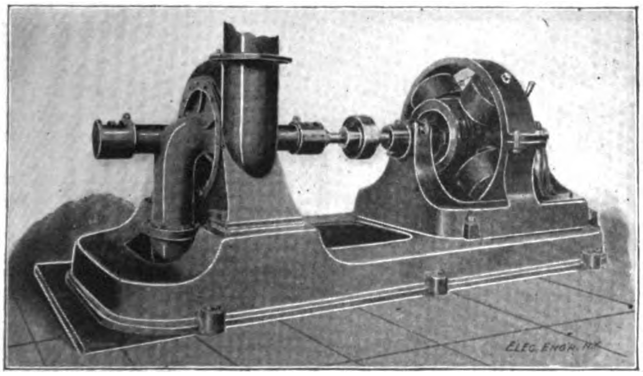
forced upward by means of this worm and rises to a height of 18 to 24 inches and falls to either side of the magazine, covering the entire grate surface. The necessary air for combustion is admitted to each stoker from the underside and meets the fuel through a number of tuyeres arranged around the magazine near its top.

The air storage for the various stokers consists of a 36-inch galvanized iron main located underneath the boiler room floor and in which an average pressure of two ounces is maintained by three Sturtevant blowers, electrically driven.

The boilers are connected by iron pipe bends with the cast steel header, extending longitudinally over the boilers, and resting upon independent iron framework, immediately adjoining the curtain wall. From this header is taken the live steam supply to the engines. The piping was installed by Best, Fox & Co.

Gate valves are located in this header for the sake of safety and reliability. This is the only steam piping in the entire station. Valves were furnished by the Chapman Valve Mfg. Co., Kennedy Valve Mfg. Co., Jenkins Bros., and John Acton.

Beneath the boiler room floor, and under the rear of the boilers, next to the fire brick flue, are located the Green economizers, so arranged as to provide for positive or natural circulation as may be desired. The front of each economizer is fitted with a sectional sheet iron filled cover so that any portion of the cover may be taken off and examination made of the sections of the economizer, and any section taken out without disturbing any other part of the economizer or dis-



KNOWLES CENTRIFUGAL PUMP DRIVEN BY ELECTRIC MOTOR.

turbing the brick work. These economizers were furnished by the Fuel Economizer Co., of Matteawan, N. Y.

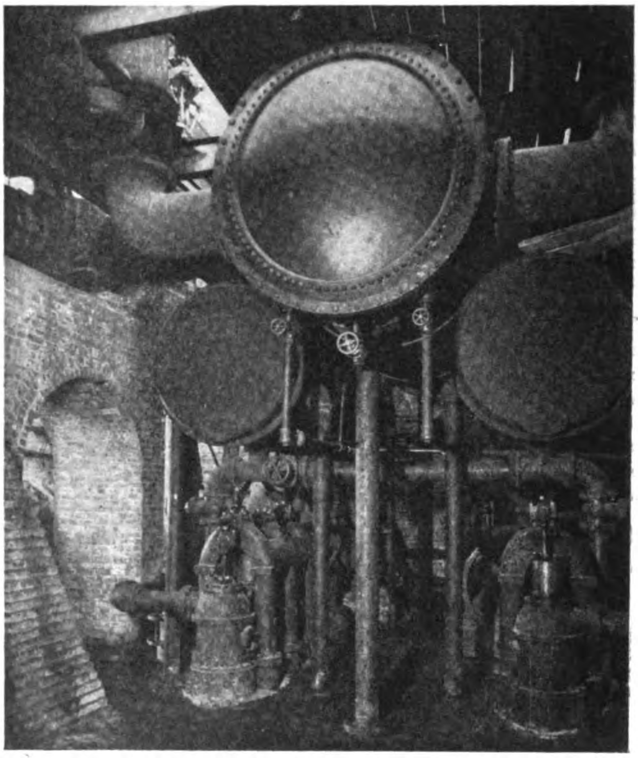
Beneath the boiler room floor, directly under the passage of the front of the boilers, are placed the boiler feed auxiliaries, blowers for the automatic stokers, and also the deep wells, used for the supplying of boiler feed water.

Quite a departure has been made in the design of this station by the adoption of electric auxiliaries throughout, steam being used only for the three engines, above mentioned, and a small air pump for compressed air. The circulating, air and boiler feed pumps are directly connected to multipolar low speed motors.

The circulating pumps are of the Knowles centrifugal type, illustrated on this page, directly connected to a G. E. multipolar motor by insulated coupling, and run at a speed of 600 revolutions, with a capacity of 3,000 gallons per minute. Two of these units are used for the 3,000 h. p. engine and one for the 1,500 h. p. and 300 h. p. engines.

The air pumps are of the Worthington steeple, three-plunger type, directly connected by means of one set of gears to a multipolar slow speed G. E. motor, running at about 300 revolutions. Two of these units are used for the 3,000 h. p. engine and one for the 1,500 h. p. and 300 h. p. engines. Each group comprises a circulating and air pump, directly connected by short piping with a Worthington surface condenser, which is located immediately beneath the low pressure cylinder, allowing, however, for suitable by-passes to free exhaust, and also for the introduction of a 2,000 h. p. vertical Goubert heater, which is placed on either side of the engine in the basement.

The speed of these air and circulating pumps is controlled



3,000 H. P. CONDENSING EQUIPMENT, UNION STATION.
(Worthington Pumps and General Electric Motors.)

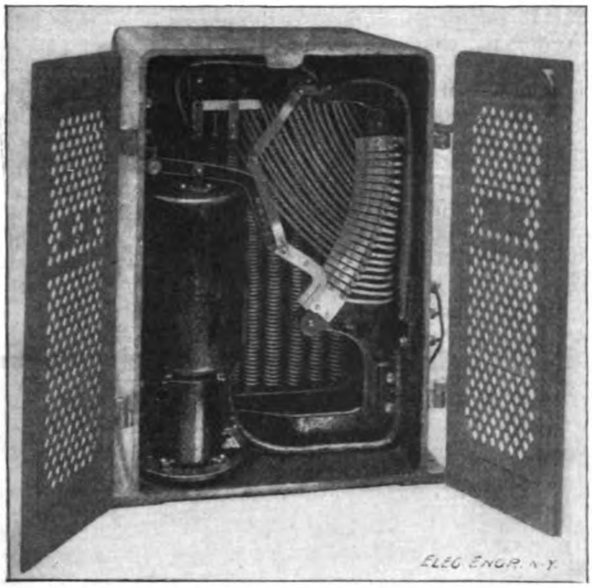
from the engine room floor by means of a See field resistance, page 18, which is cut in and out of the field circuit motors, and the equipment is so arranged, even to its oil system, as to require no attention whatever beyond an occasional inspection.

The total circulating water piping for each unit of 1,500 h. p. does not exceed 12 feet in length, there being but five joints. The total connection of the air pump piping is about 14 feet long. The total length of the piping between the low pressure engine cylinder and the condensers, including the piping to the heaters for each unit, does not exceed 20 feet in length, there being not more than seven joints. As will be seen from the above, special attention was paid to short connections.

The boiler feed pumps are of the Worthington horizontal, three-plunger type, directly driven by means of one set of gears by a G. E. multipolar, slow speed motor, running at 250 revolutions. The speed of each unit is varied from the boiler room floor by means of governing resistance cutting in and out of the field circuit. In addition to this, the starting and varying of the speed of the motor is done automatically, depending upon the pressure of the feed pipe system. Each boiler feed pump is directly connected to the feed system, which passes through Goubert heaters and auxiliaries into the main line, from which are taken the feeds to each boiler, and which feeds are con-

trolled by the firemen by ordinary hand valves. Suitable by-passes are arranged for each piece of apparatus, so that any system of feed is provided for.

The suction of the feed pumps is connected to a main, directly connected to a number of driven wells, which are the main source of water supply, and also to two large water tanks, where all particles of sand or suspended matter can settle. These tanks are supplied from the wells by a direct connected electric

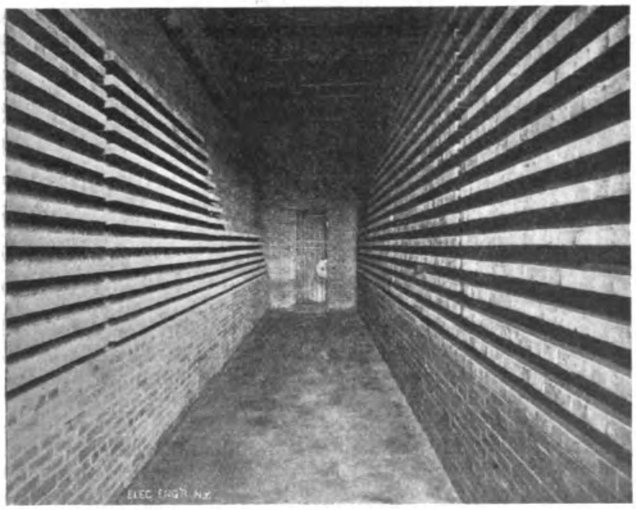


RHEOSTAT FOR CONTROLLING AUXILIARIES.

Deane duplex pump, of 300 gallons capacity. Into the tanks are also connected all the leaders of the building by means of a by-pass, so that rain water can be used as boiler feed during heavy storms.

The Sturtevant blowers, which supply air to the stokers, are secured to the ceiling of the basement, or the underneath side of the boiler room floor, and are directly connected by belts with slow speed multipolar motors.

All motors, above described, used for auxiliaries, blowers, etc., are of the General Electric 230-volt type, and are supplied with current from the vertical, triple Lake Erie engine unit.



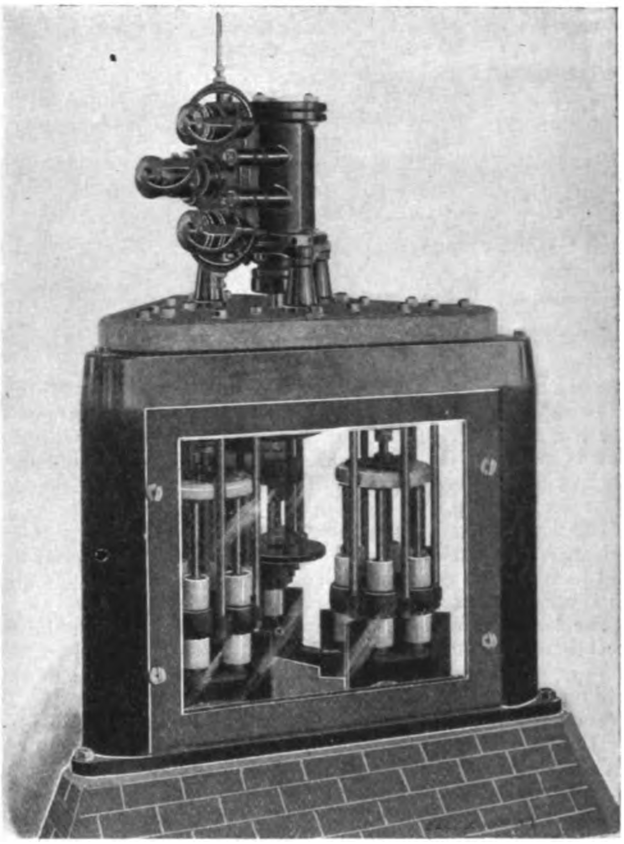
HIGH TENSION VAULT SHOWING FIREPROOF SHELVING FOR CABLES, UNION STATION.

before mentioned. Thus there is no steam device,—excepting a small steam air pump,—which has a lower economy than 16 pounds of steam per indicated h. p., which is the economy of the Lake Erie engine under full or three-quarter load, at which load it will always be operated.

This arrangement of electric auxiliaries enables the auxiliary equipment of the station to be ruduced from 12 to 40 per cent., as regards steam economy.

AIR AND OIL SYSTEM.

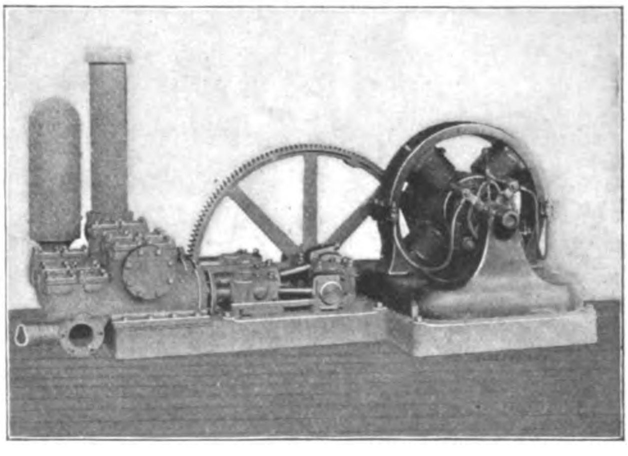
Compressed air at 40 pounds per square inch is used in the Union Station for the blowing out of boiler tubes (in place of steam, as formerly), for cleaning all the electrical equipment, for handling the oil and for the operation of the pneumatic electric switches described below. To render this part of the plant as reliable as possible, the air is compressed by direct con-



6,600-VOLT ELECTRO-PNEUMATIC SWITCH.

nected air pumps, supplied directly from the main steam line, the air being stored in two tanks, one located in close proximity to the electrical gallery for use at that point, and the other in the boiler room. The air compressor was furnished by Westinghouse, Church, Kerr & Co.

The oil is supplied to each engine by positive feed pumps,



WORTHINGTON TRIPLEX BOILER FEED PUMP, DRIVEN BY GENERAL ELECTRIC MOTOR.

operated from the engine, and is discharged, after use, into tanks connected with filtering apparatus, and is then lifted, by means of compressed air, into the main tank which supplies the engine pumps. Besides this system, facilities are provided for hand oiling. All motors throughout the plant have self-oiling

bearings, and the pumps are equipped with grease cups, so as to render little attention necessary.

THE SMOKESTACK.

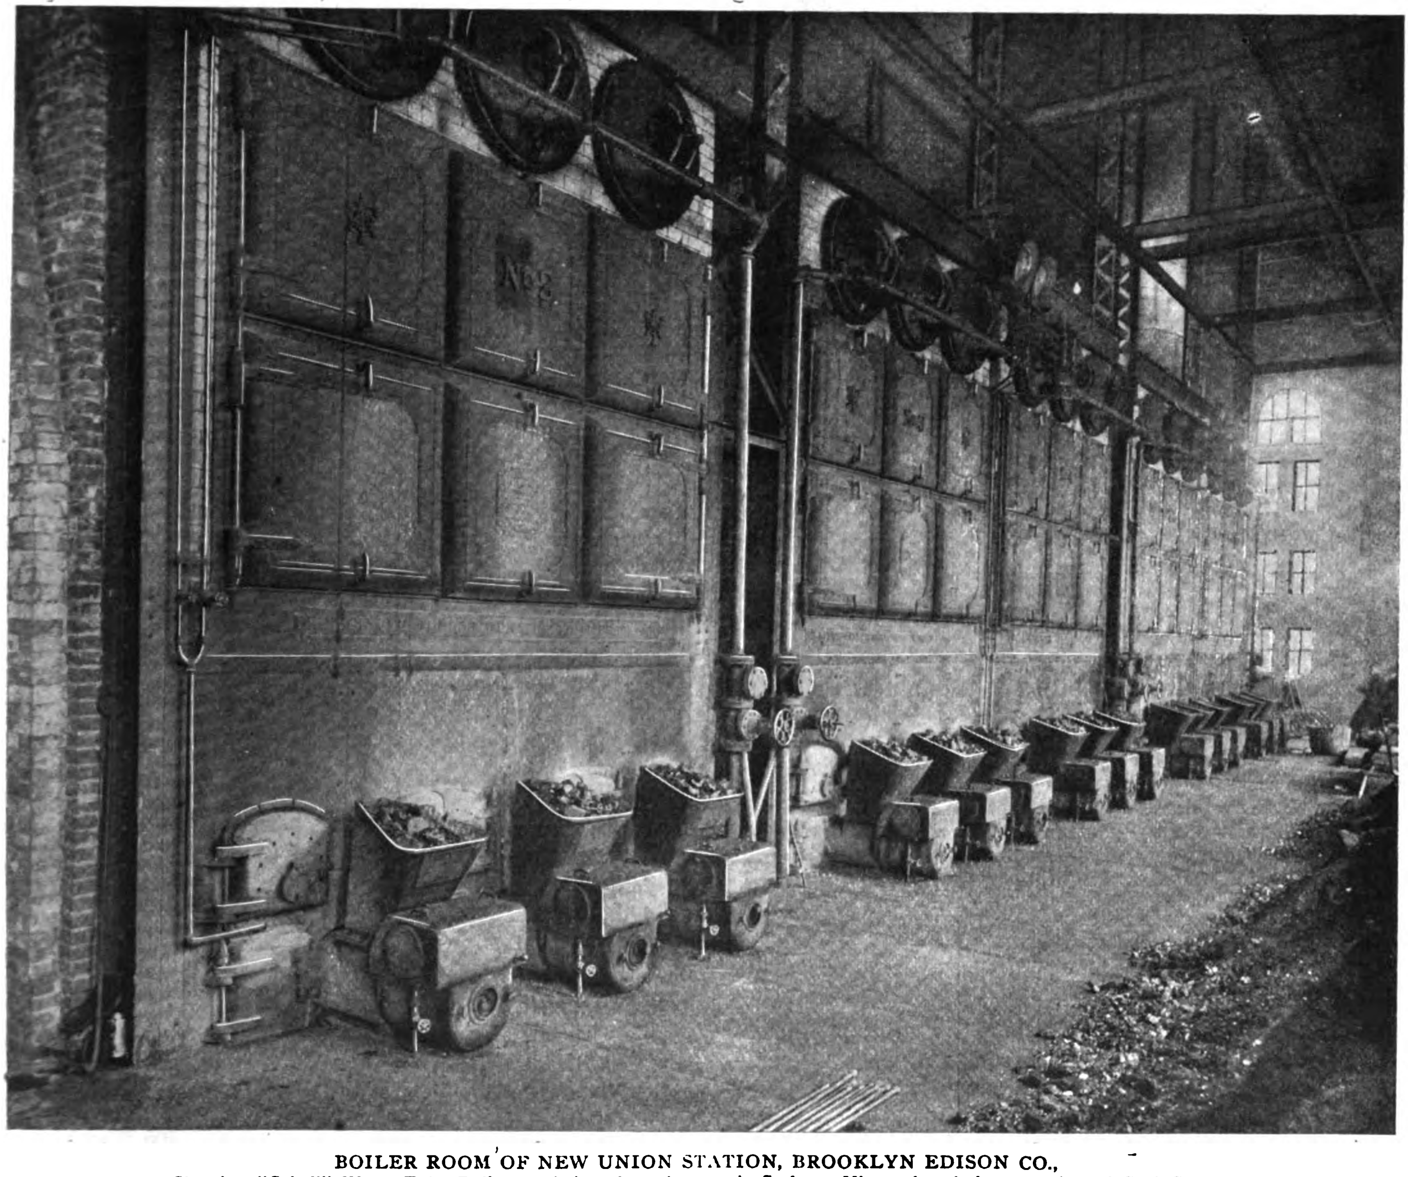
The stack, which is constructed of steel, and is the tallest of its kind in the country, rests upon a foundation of brick, into which the flue openings are made. The base of the stack measures 25 feet in diameter and is bell shaped to about 25 feet in height, where the diameter is reduced to 15 feet 6 inches. From this point to the top the stack tapers gradually to 12 feet. Its total height is 240 feet, the plates used in its construction varying from ⅝-inch thick at the base to 5-16 at the top. The stack throughout is lined with Sayer & Fisher "A.1" fire brick, backed by red brick. The supplement accompanying this number gives detail drawings of the stack.

COAL STORAGE AND COAL AND ASH HANDLING MACHINERY.

Extending out from the southern part of the water front of the company is the coal pier, shown on page 20, built to accommodate vessels of any length and draught. On this pier travels an unloading tower which is operated entirely electrically by one man. The electric hoist, operated on the Leonard system, removes the coal from the boat on either side of the pier with a one-ton shovel and deposits it in a hopper in the center of the tower. The coal then falls by gravity on to the crushing rolls, which are driven continuously from a motor dynamo which supplies the hoist above. From the crushers the coal passes to a Clarke self-weighing and self-feeding scale, which automatically records the weight of the coal on a dial. From the scale the coal descends into a cable car located beneath the tower and running on tracks laid on the pier.

The tower is capable of moving lengthwise to the pier, so as to render it possible to unload coal at any point on either side of it. From the tower the coal is conveyed by means of a shuttle cable road up an incline to a 2,000-ton coal storage bin, located about 300 feet back of the tower and 60 feet south of the main building. The motor operating this shuttle road is automatically stopped and started by the weight of the coal that drops into the cable car, and in the following ingenious manner:

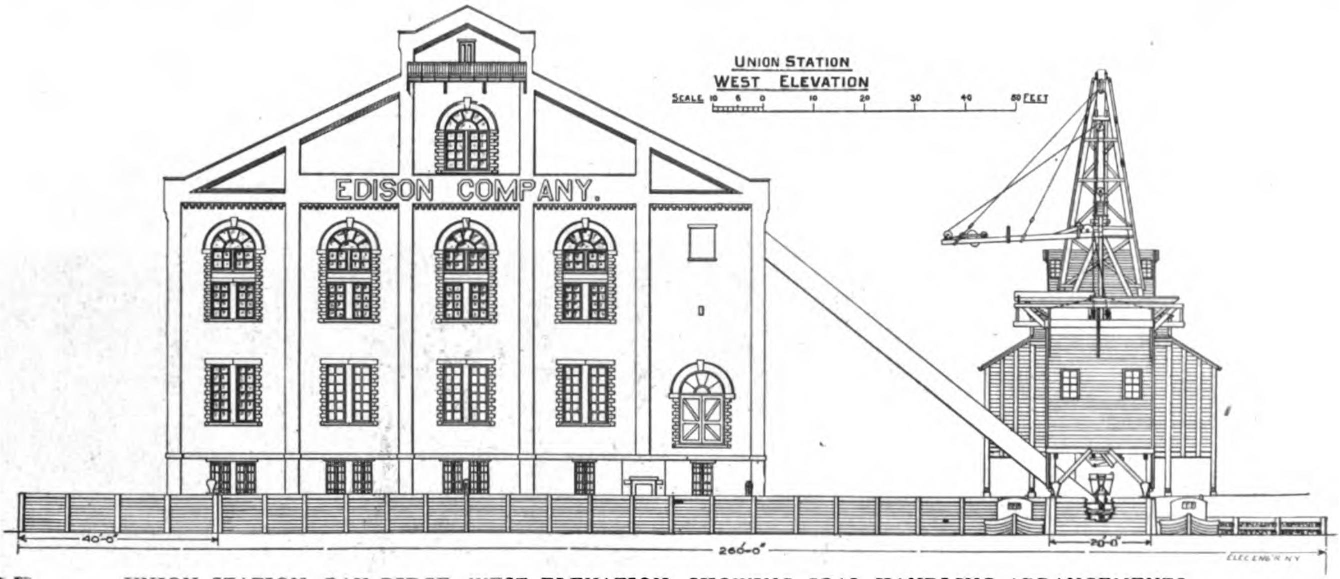
Each car when loaded to a certain point settles on its springs and makes contact with a third rail. The cable drum is thereby started and the car moves to the main storage bin. In moving forward it closes the chute through which it was filled, which chute remains closed until the empty car which returns to the dock as the loaded one moves from it, opens it again. The loaded car empties itself at any point desired; the car thus emptied is raised in its springs, breaks the circuit and is stopped. The operation is repeated when the car, which is now being filled, again makes contact with the third rail. The arrangement is thus entirely automatic.



BOILER ROOM OF NEW UNION STATION, BROOKLYN EDISON CO.,
Showing "Cahall" Water Tube Boilers and American Automatic Stokers. View taken before erection of Coal Conveyers.

The coal storage is a wooden structure, 100x40 feet, and 30 feet high, proportioned and built for the storing of 2,000 tons of soft coal. Under the pocket, and for its entire length, runs a conveyor of the Link Belt type, installed by Mr. Augustus Smith; this conveyor takes the coal from the various chutes and deposits it into another conveyor, which, carrying it up an incline of 30 degrees, transfers it to a third con-

veyor, which deposits it into hoppers over the boilers, which have a capacity for two days' supply. This arrangement is shown in the sectional view in the accompanying supplement. From these hoppers the coal passes down a chute and through a self-weighing scale (one for each battery of boilers) into a small distributing screw conveyor, which feeds it to the stokers.



: UNION STATION, BAY RIDGE, WEST ELEVATION, SHOWING COAL HANDLING ARRANGEMENTS.

Thus the entire operation from the unloading of the coal on the tower to the burning of the coal in the furnace is performed automatically. The coal unloading machinery was installed by Messrs. John A. Mead & Co.

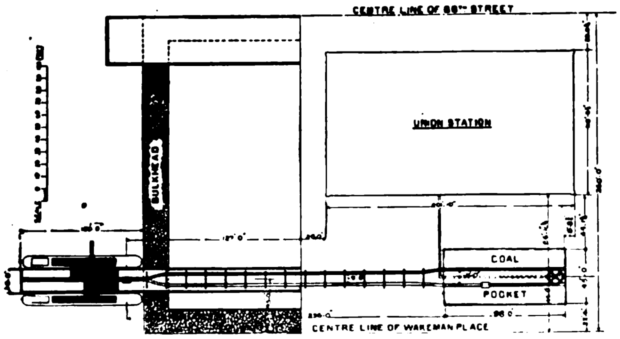
In front of the economizers, and under the furnaces of the stokers, are placed the ash receiving hoppers, beneath which runs an ash car the entire length of the boiler room, and through a bin in the west end of the building, to a point between two bulkheads, where the ashes are used for filling-in purposes.

THE OVERHEAD TRAVELING CRANE.

For convenience during construction and in making of repairs, should any become necessary, there has been erected in the engine room an electric crane built by the Shaw Mfg. Co. This crane, which has a capacity of 25 tons, spans the engine room, a width of 68 feet, and travels its entire distance. It is designed to move at a speed of 200 feet per minute. The trolley moves horizontally 80 feet per minute, and the hook rises or falls at a speed of 50 feet per minute. These movements are effected by three electric motors. All supplies for the station may be run into the building on flat cars over a specially constructed trestle, whence the crane may move them to any point desired.

THE GENERATORS AND MOTORS.

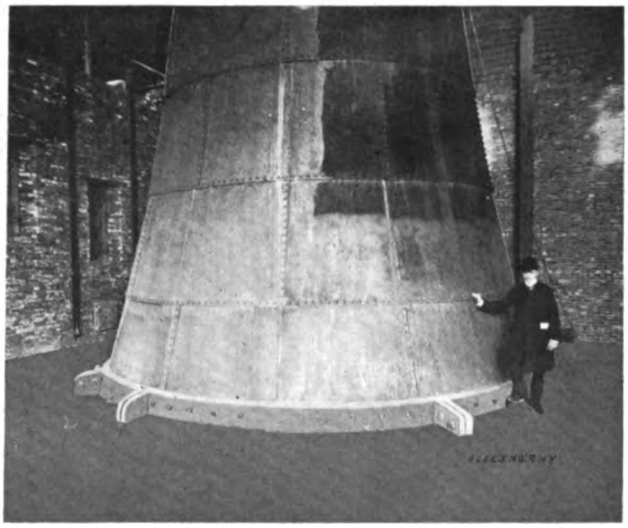
The present main generators of the station are two in number, and are of the three-phase, high voltage type. These machines are of the General Electric revolving field, standard armature construction, the fields being excited with current at 115 volts pressure by means of small collector rings placed on the shaft. The capacities of the machines are 2,000 and 1,000 kilowatts, respectively, with an allowance of 25 per cent. for overload. A voltage of 6,600 volts is delivered directly from the armature at a speed of 75 revolutions per minute, without step-up transformers.



GENERAL PLAN OF COAL HANDLING ARRANGEMENT.

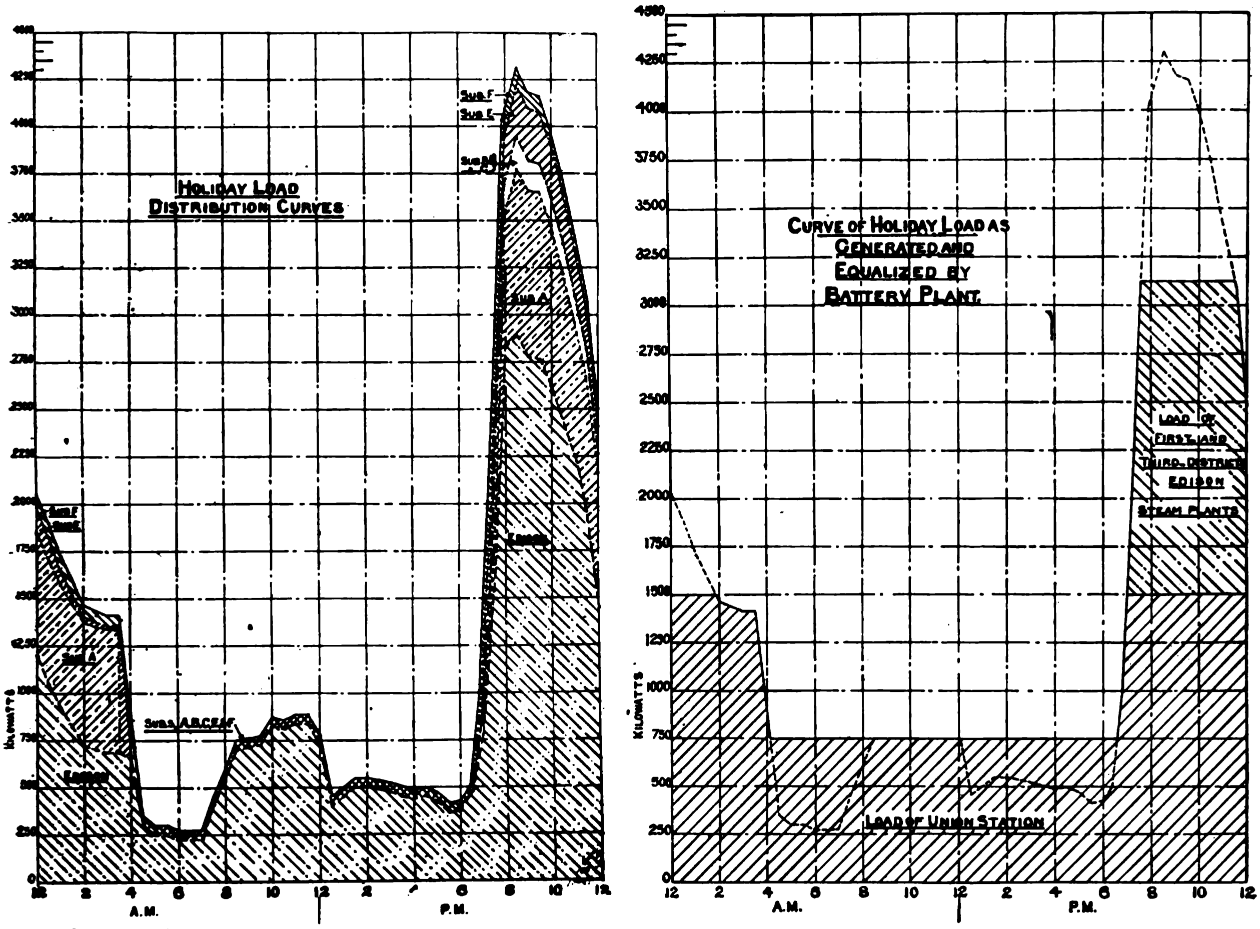
This great dynamo was not designed simply to give its rated output without injurious heating, but rather with a view to obtain the maximum economical efficiency; that is, a comparison was made between the interest on its first cost and the cost of its operation, and a design adopted which would conduce to the maximum general economy. Some of the most interesting features of this machine are the following:

The armature laminations are mounted on the interior of a box frame of very great rigidity, openings for ventilation being provided at intervals. The armature coils are placed in slots in these laminations and held in place by wooden wedges. The method of insulation of these coils has been very carefully worked out; the insulation of each coil is wound on the coil itself, practically no slot insulation being used. The machine has been tested in the General Electric Co.'s factory with 30,000 volts alternating potential difference between the winding and the iron. The armature frame is illustrated in the initial "O" at the head of this article.

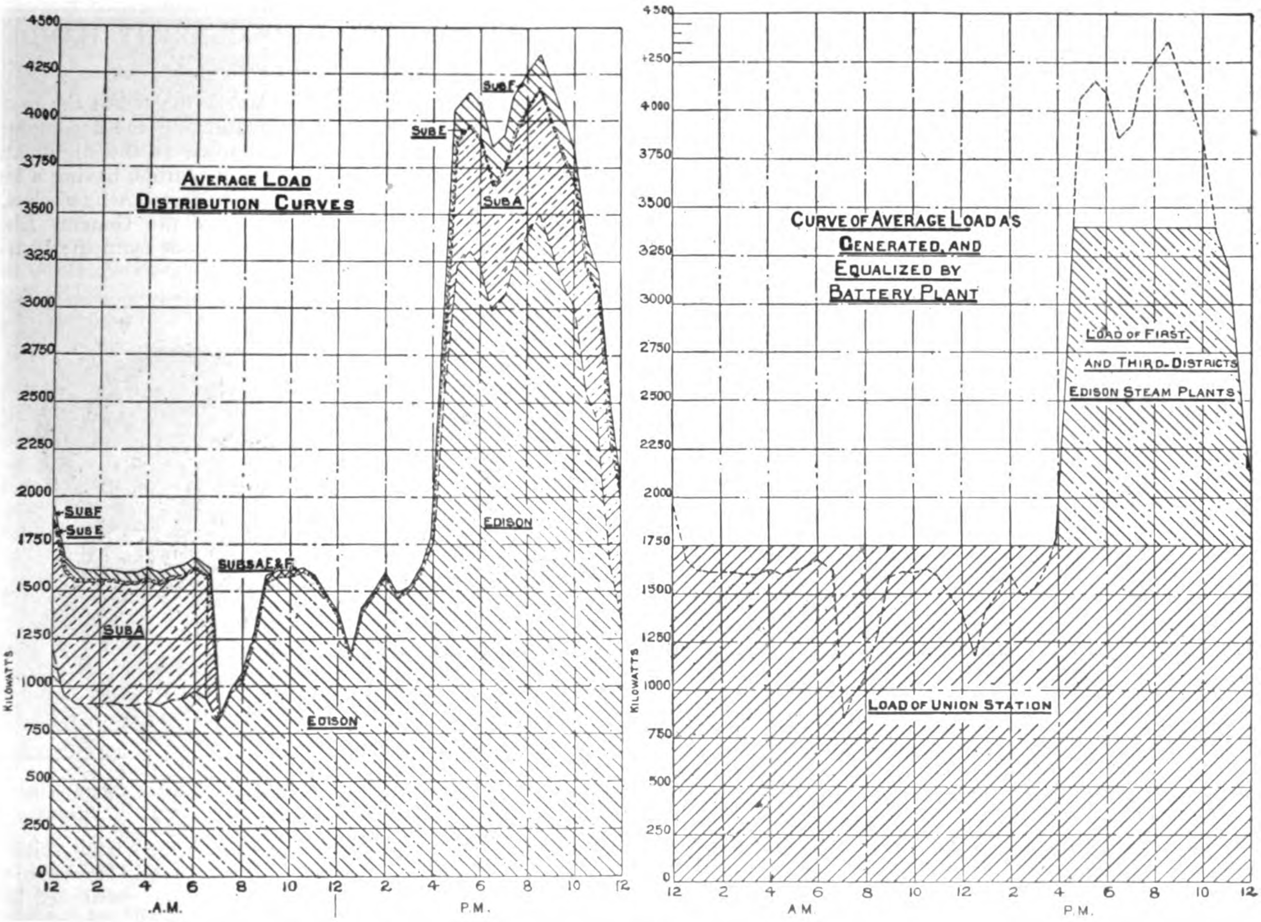


BASE OF GREAT SMOKE STACK, UNION STATION.

The field structure consists of a cast iron spider which carries a steel ring; this steel ring is cast and finished smooth. The pole pieces are built up of laminations and are bolted to this steel ring. The field coils are placed upon the pole pieces before they are attached to the ring, each coil consisting of a spiral of strip copper wound on edge, the successive turns being insulated from one end by paper. This makes an extremely compact coil, practically indestructible, since the heat is not



CURVES SHOWING HOLIDAY LOAD DISTRIBUTED ("A"), AND AS EQUALIZED BY STORAGE BATTERY ("B.")



CURVES SHOWING AVERAGE LOAD DISTRIBUTED ("C"), AND AS EQUALIZED BY STORAGE BATTERY ("D.")

at all confined by the insulation; the coil remains at practically the same temperature throughout its mass and runs very cool. The field is excited with a direct current at 125 volts, this current being delivered through a pair of collector rings on the shaft. Carbon brushes are used on these collector rings, and the arrangement is such that they require little or no attention.

The armature structure of this machine is mounted on cast

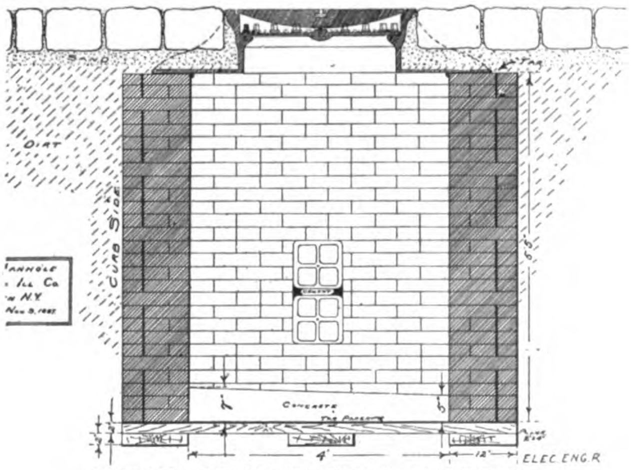
McROY CONDUIT FOR HIGH TENSION CABLES.

iron rails attached to the foundation. It is so arranged that it can be slid along on these rails into a position where its coils clear the field coils. When in this position any of the coils of armature or field can be removed and replaced. The following are the principal dimensions of the machine: Outside diameter of armature frame, 21 feet, 2 inches; outside diameter of revolving field, 16 feet, 7⅜ inches; distance between rails, 25 feet 5½ inches; length of rail, 7 feet 3 inches; diameter of shaft, 27 inches; height above floor line, 13 feet 10 inches.

This machine is wound for 6,600 volts, that being the voltage used in transmission. Its design is such that it can be built for a very much higher voltage.

THE AUXILIARY ELECTRIC EQUIPMENT.

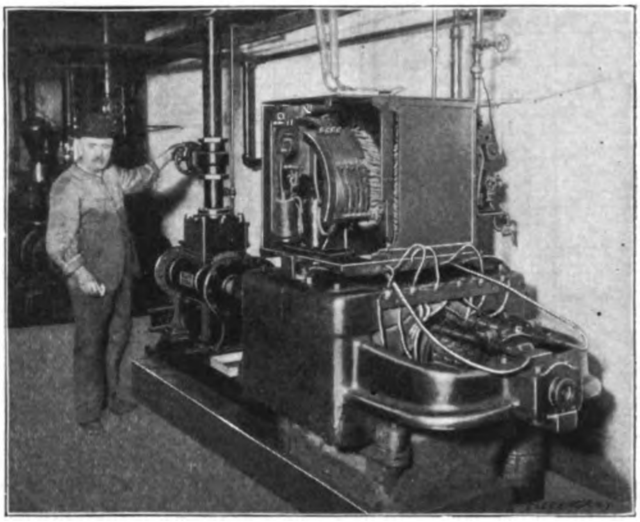
This consists of two multipolar General Electric exciters, each directly connected to the shaft of a vertical compound engine, running at 400 revolutions. These exciters are wound to



SECTION OF WATER-TIGHT MANHOLE.

give 125 volts at 400 amperes each. There are also two multipolar General Electric generators, direct connected to the vertical triple expansion Lake Erie engine, wound for 150 volts and 666 amperes, at a speed of 175 revolutions. These two generators are connected on a three-wire system and used to operate the 230-volt auxiliary equipment of the plant, and also to furnish the lighting.

The multipolar motors running the blowers for the automatic stokers are of 25 h. p. each, at a speed of 580 revolutions. The multipolar motors used for operating the circulating pumps are of 20 h. p. each, at 610 revolutions; while the motors used for operating the air pumps are 15 h. p. each, at 260 revolutions. The multipolar motors used for operating the boiler feed pumps are of 20 h. p. each, at a speed of 280 revolutions, and those

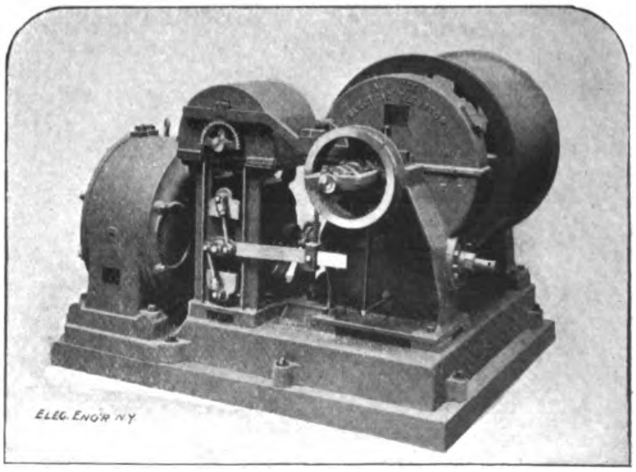


OTIS-QUIMBY ELECTRIC ELEVATOR PUMP.
(In Municipal Building.)

used for operating the coal conveyor system are multipolar machines of 5, 10 and 15 h. p. respectively, while the coal hoisting tower is operated by a 100 h. p. motor, supplied by a 65x55 k. w. motor-generator on the Leonard system. The C & C motor operating the well pump is of 20 h. p. at a speed of 1,000 revolutions, and is directly connected to the pump by means of a double screw gear of the Whittier type. All these motors, excepting that on the well pump, are of the General Electric type.

THE SWITCHBOARD AND CURRENT HANDLING ARRANGEMENTS.

The main switchboard of the plant is located at the east end of the building, shown in the elevation on the accompanying supplement. This switchboard, known as the high tension, three-phase board, is of blue Vermont marble, having a length of 49 feet 6 inches and a height of 12 feet. All switches, excepting as hereafter mentioned, are of the General Electric knife blade, quick-break type, mounted out from the board on



A. B. SEE TWO-PHASE ELECTRIC ELEVATOR.

corrugated rubber insulators. The ammeters and voltmeters are of the Thomson inclined coil type, and Thomson wattmeters are used on all electrical generators mentioned below.

The switchboard has a space immediately in front of it of 50x

6 feet, while back of it is a room 10x50 feet. In this room are located the field rheostats for the large alternators, connected by means of cables and a regulating head, mounted on the switchboard itself. The switchboard is provided with three buses, and knife blade switches are used in changing from one bus to the other. The entire switchboard, consisting of 12 panels, is divided into seven feeder and five machine panels. The board was built at the works of the General Electric Co.

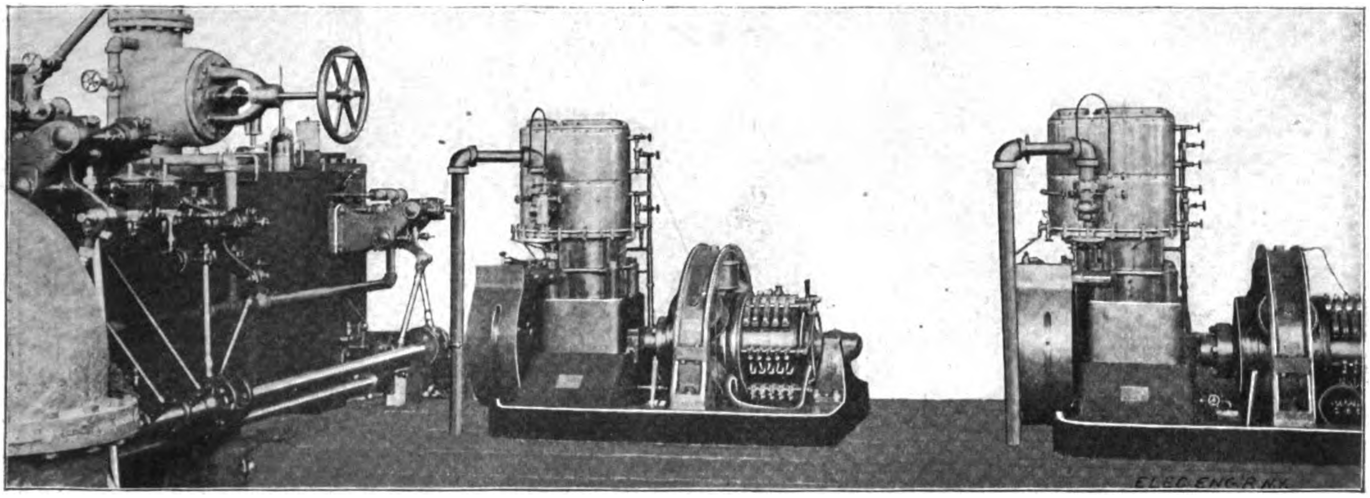
Electro-Pneumatic Switches.—Behind the board, in the room above mentioned, are four 7,000-volt electro-pneumatic cylinder switches, mounted on brick pedestals, as shown on page 18. One of these switches is placed in the main circuit of each generator, while the other two are connected between the busses to be used for synchronizing. These switches are the first efforts to combine the reliable pneumatic devices of the Union Switch & Signal Co. with the high tension electrical switch, manufactured by the General Electric Co.

The electrical portion of the switch consists of a three-armed spider, each arm carrying a number of plungers, which make contact inside of porcelain tubes. A group of contacts is placed in each wire of the three-phase system. The three groups are operated simultaneously by means of the three-armed spider, connected to an electro-pneumatic motor of the piston type, operated on an air pressure of 40 pounds, and controlled electrically by means of a small switch on the front of the switchboard.

The wiring from the auxiliary switchboard to the different auxiliaries of the station consists of solid copper rods with three-wire braid covering, suspended by specially designed porcelain clamps, making a rigid piece of work of pleasing appearance. These conductors terminate at specially designed automatic resistance boxes, so that the starting of each motor is accomplished by simply closing its main switch. Thomson wattmeters are provided for every part of the electrical equipment. Each three-phase generator is connected to a 6,600-volt alternating current wattmeter, and each direct generator is connected to a 125-volt Thomson wattmeter, this arrangement providing for the metering of all current generated by the plant. In addition to these, there are wattmeters on each consumption circuit in the station, so that the power consumed by the auxiliaries, coal handling equipment, etc., can be easily ascertained.

STATION LIGHTING.

The lighting of the main engine room is accomplished by means of ornamental lamp posts, built by the General Incandescent Arc Light Co., upon the top of which are placed enclosed arc lamps of the General Electric type. These lamp posts are adjustable from the floor, slipping into sockets, thereby rendering it possible to instantly shift them if necessary, or to remove them for the purpose of handling parts of the equipment with the crane. The boiler room is lighted by



DIRECT CONNECTED EXCITER UNITS, UNION STATION.

On the front of the switchboard gallery, and immediately in front of the generator panels, are located seven black enameled slate field rheostat boxes controlling seven exciters, four of which are at present installed. On the top of these boxes, supported on brass stands, are the direct current voltmeters and ammeters for the exciters. Small baby knife switches on the sides of the boxes operate the electrically controlled switches on the auxiliary switchboard, described below.

Auxiliary Switchboard.—An auxiliary switchboard of black marbleized slate is located on the engine room floor in the west portion of the building, immediately back of the vertical triple expansion engine. On this board are mounted electric switches of 1,000 ampere capacity, controlling circuits for exciters, pumps, lighting, etc., and operated by small secondary circuits from the high tension switchboard, above mentioned. This arrangement obviates the necessity of carrying heavy copper cables a distance of 230 feet, and return, for the sake of connecting and disconnecting them, and at the same time puts the handling of the entire electrical equipment of the plant in the hands of the switchboard operator. The switches on these boards were furnished by the General Electric Co.

Station Wiring.—The cables leading from the generators to the main switchboard are drawn through glazed tile duct, of the McRoy and Camp type, which ducts are built into the walls of the building. Where they pass through the vault they rest upon brick shelves, formed by building ordinary brick into alternate layers of headers and thick courses. This arrangement does away with all insulators for supporting the cable, and provides a fireproof compartment for each separate three-wire cable. Seep age 18.

enclosed arc and incandescent lamps, which also take care of the coal storage, unloading tower, etc.

It is the purpose of the company to provide for all further increase of exciter or auxiliary current by means of rotary transformers, as it was not deemed advisable to introduce them in the main station at the outset.

TRANSMISSION AND DISTRIBUTING SYSTEMS.

All the current generated at the Union Station is transmitted to the different stations and sub-stations by means of duplicate underground three-wire lead-covered cables, drawn through McRoy earthenware ducts, all joints being made in moisture-proof manholes; a section of one of the latter is shown on page 22. All cables were furnished by the Standard Underground Cable Co., and are of paper and compound insulation. All sections of cable were tested at the factory in accordance with the specifications by a representative of the Edison Company for one hour with from twelve to fifteen thousand volt alternating current, and a test was also made after the entire system had been completely laid by the contractors. These cables comprise 30 miles of three-conductor, ranging in size from No. 4 to No. 6 B & S.

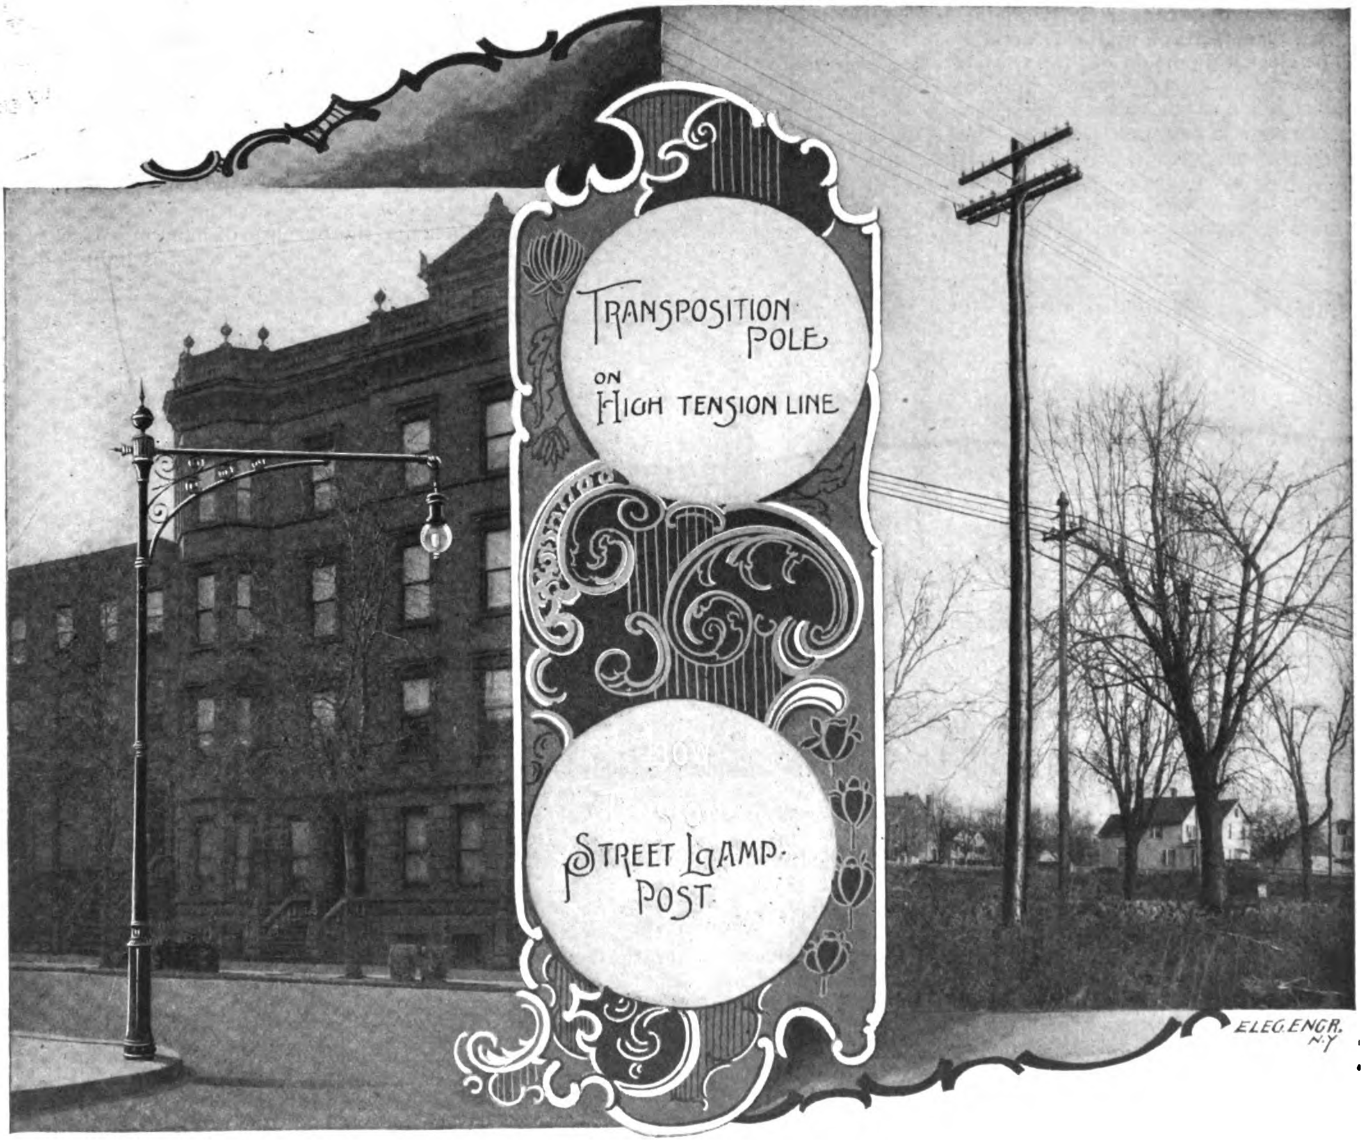
The low tension distributing systems are made up of the familiar Edison three-wire system, the conductors being of copper rods in iron pipes, insulated in the usual manner by compound, etc., with junction boxes located at the principal street corners or points of union of the mains and feeders.

The overhead three-phase transmission system into suburban localities is erected on heavy poles on double petticoat deep groove glass insulators, with frequent transpositions in the line.

shown on this page. All lightning arresters are in the form of barbed wire conductors, erected directly over the three-phase conductors, and grounded at frequent intervals.

The two-phase distributing system is, in some localities, underground, has the converters located in large moisture-proof manholes and the secondary current distributed through regular Edison underground three-wire tubing. As this system is used to "pioneer" the three-wire direct current Edison low tension system, the change can be made easily by replacing the converters with direct current feeders laid to the main direct current distributing points. This is the only change necessary, since the house wiring, service connections, meters, etc., are similar in both systems.

The two-phase high tension distributing system, when erected overhead, consists of four primary conductors (2,400-volt) placed on the top cross-arm, and directly below are run the three heavy conductors of the secondary system. Between these two lines, at necessary intervals, are connected in the two-phase transformers, thus making a continuous secondary system with transformers, fed in multiple, at different points.



STREET LIGHTING SYSTEM.

The Brooklyn Edison Company operates about 700 low tension enclosed arc lamps for street lighting. These lamps are mounted upon ornamental iron posts, one of which is illustrated on this page, and connected with the underground Edison three-wire system. To facilitate the trimming of the lamps a reel and flexible cable is used whereby they can be lowered to the street level.

Inserted in the circuit of each lamp, and in the base of the post, is an automatic clock switch. The switches which are now being installed are of the self-winding, self-setting type, furnished by the General Incandescent Arc Lighting Co., of New York. The winding is done periodically by current taken from the mains, and the setting of the time switch to correspond with the different periods of turning on and off the lamps during the year is automatically accomplished by means of a cam, shaped to conform to the city lighting schedule. Thus each lamp is continuously, automatically lighted and extinguished to correspond with the city lighting schedule, the only attention required being trimming.

High tension series lighting is furnished in outlying portions of the city, there being now 1,750 high tension street lamps of 1,200 c. p. in use. The lamps are of the open arc type, mounted on ornamental standard or adjustable mast arms on a neatly painted wooden pole, as shown on page 25. The Company has now upon its circuits, including all systems, commercial and city, 6,317 arc lamps. The lamps in use comprise the 1,200 c. p. low tension open arc, 1,200 c. p. low tension enclosed arc, 600 c. p. low tension open arc, 1,200 c. p. alternating (60-cycle) open arc, 1,200 c. p. alternating (60-cycle) enclosed arc and the 1,200 c. p. high tension series arc.

LOAD DIAGRAMS.

All the energy of the company is now generated at three stations, the two stations which were former steam plants of the company, and located in the city proper, now operating only eight hours a day. By means of the Union Station and the two steam stations, operating eight hours a day, the load diagram "A," on page 21, which shows the distributed

energy used during a holiday, takes the form shown in diagram "B," which shows the corresponding current generated and equalized by means of storage batteries.

Diagram "C" shows the distributed load of an average day and diagram "D" this same load as generated and equalized by battery plant.

The two load diagrams, "A" and "C," show the system under the worst and best conditions, 250 of the days of the year having diagrams similar to diagram "C," and the remainder of the year similar to that of diagram "A."

THE LIGHTING AND POWER WORK OF THE COMPANY.

It goes without saying that the uses to which the current is put in various situations now reach into the hundreds.

In the field of incandescent lighting, stores, offices, theatres and factories, as well as private dwellings, have constantly taxed the company's current generating resources. Now that the new Union Station, with its high tension current, permits of sub-stations being planted in the midst of residential districts without in any way spoiling the appearance of the neighborhood, or making their presence objectionable to adjoining tenants, a large increase in residence lighting may be looked for. That the company is alive to its opportunities is patent by the erection of the Carroll street sub-station, which will,

LOW TENSION DOUBLE ARC LAMP POST.

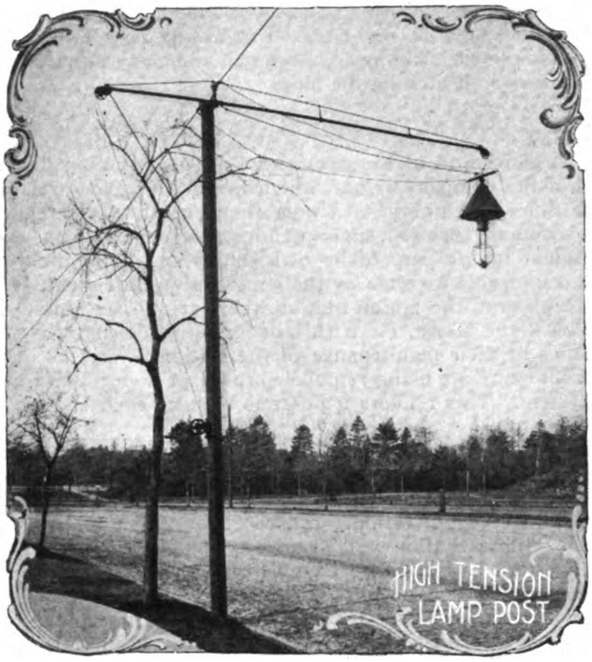
without doubt, soon find itself fully taxed by the demands of residents of the Park Slope.

As briefly referred to in the introductory, the Brooklyn Edison Company was the pioneer in the introduction of the low tension arc lamp and the thousands of them now burning nightly on their circuits, both as commercial and as street lights, testify to the long-headedness of those who introduced them. We might mention here that the company is now extending its circuits into Greenwood Cemetery, where it is making connection to the elaborate heating and lighting installation in the Mackey Memorial Tomb.

As to motors, the company, until the inauguration of the Union Station, has long been at its wits' end to supply the demand, both permanent and temporary. Only recently, for example, it was called on to furnish 100 h. p. to a factory, within twenty-four hours after the receipt of the order. It required considerable nerve to accept the order, but at the time specified the wheels were moving. Of course such "rush" orders are not the rule, but their successful carrying out shows what can be done when the emergency arises.

The uses to which direct current motors are now put on the Brooklyn Edison Co.'s circuits cover almost the entire range of the trades, from the running of ice cream freezers to that of printing presses, and taking power varying in amounts from ¼ h. p. up to 250 h. p. and more.

Not a little of the company's 2-phase system is utilized in



HIGH TENSION LAMP POST

driving electric motors, which are rapidly multiplying as their merits and economy become better known. As an example of this class of work we might mention the electric elevator in the St. Mary's Hospital, Brooklyn, which is running on the company's two-phase alternating system, and is one of many built by Mr. A. B. See, and installed in various buildings, hotels and private residences. These machines, one of which is illustrated on page 22, run with excellent uniformity of speed, stopping and starting nicely and require practically no care. Where it is desired to avoid the expense of an elevator attendant, the leading elevator manufacturing companies have devised a system by which, on touching a button the elevator ascends to the desired floor and stops there. The ability to run motors

HYDE & BEHMANS' THEATRE.

from multiphase alternating circuits greatly increases the scope of this method of distribution.

As to elevators run from direct current circuits they are numbered by the score. Perhaps as good an example as any is that to be found in the Edison Co.'s Pearl street station, which takes the visitor from the ground floor to the executive offices of the company. This elevator operates on the Leonard system.

Another very interesting elevator installation is that in the

Municipal Building, where an Otis electric motor drives a Quimby screw pump that forces the water to a tank on the roof, that gives the desired pressure for the hydraulic elevators.

It seems scarcely necessary to mention the work of the current driving thousands of small fans all over the company's territory. The extent of this territory, by the way, is well shown in the map of the new Borough of Brooklyn, on the supplement accompanying this issue, in which the company's circuits are indicated in red lines. Extensions now under way and contemplated in the near future will add many more streets to those now indicated on the map.

STATION MANAGEMENT, METER CHARGING, ETC.

The organization of the operating and construction departments of the company is one which brings into close relation all the different employés. Under the general superintendent of the company are ten superintendents of departments, each department taking care of its own duties and being held directly responsible for such by the general superintendent. With the exception of the Union Station, there are no station superintendents, the steam, electrical and building departments cooperating in their maintenance of the stations. The accounts of the company are being remodeled to adapt themselves to the new system. This renders it possible to keep each station account separate.

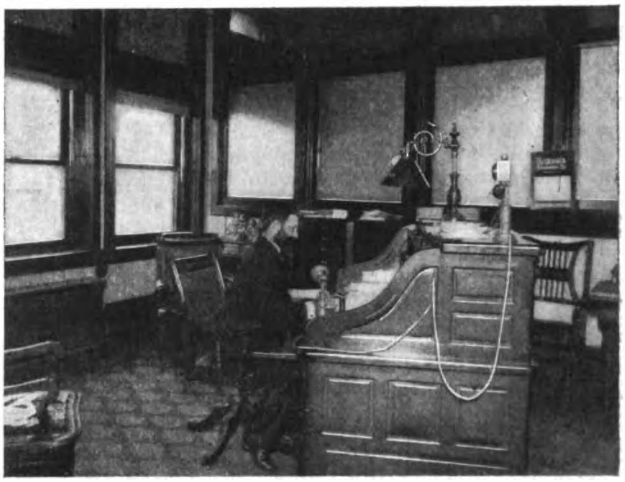
With the present 20,000 h. p. Union Station behind it, with a capacity for readily increasing to 60,000 h. p., there is evidently nothing to prevent the company from reaching out for business in every direction. Indeed it is not at all unlikely that the Union Station will eventually supply current to the entire western half of Long Island from north to south shore.

The company is now in a position to extend its system to the neighboring towns on Long Island, utilizing 12,000-volt. three-phase transmission. Work has already been started on one 12-mile line (three miles being submarine cable) which will transmit by May 1 of this year not less than 800 h. p. at a pressure of 6,000 volts. This current at its distributing point will be transformed by the local company into single-phase alternating, 60-cycle, high tension direct current for series arc lighting, the distance from the Union Station to the furthest series lamp being 15 miles.

METER ROOM, FIRST DISTRICT STATION.

All three-phase energy entering a sub-station is measured by wattmeter before it is distributed to the various transformer devices; all energy leaving a sub-station in any form whatever is measured by wattmeter, as is also all energy used in a sub-station for lighting, heating, etc.; all energy generated and used at, as well as that leaving the Union Station, is metered, so that a complete wattmeter record of the entire system is obtained. It was not thought necessary, on account of expense, to separately meter the energy entering the various transforming devices, as tests at frequent intervals will satisfactorily determine, mechanically and electrically, the efficiency.

All business done by the company is directly on a meter basis, the Edison electrolytic and Thomson mechanical meters being used exclusively. The Brooklyn Edison Co. was the first in this country to give discounts to any extent to customers for long hours of burning. Recognizing, however, that the business of the company should be the supplying of electrical energy pure and simple, independent of the purposes for which it is used, the company contemplates making such a departure



OFFICE OF MR. ROYAL C. PEABODY.
(Secretary and Treasurer.)

in its method of charging for current as will further reduce the price of current.

It has been the practice of the company to renew, at regular intervals, incandescent lamps installed among its customers. All incandescent lamps are renewed at stated intervals and replaced lamps returned to the lamp testing room, retested, returned to the store room and reissued or destroyed, depending upon the reading of the photometer, etc.

The work of the Brooklyn Edison Co. has been remarkable not only on account of its complete execution in such a short time, but also on account of the fact that all the work on the entire system, from the architectural designing of the building to the arrangement of the various mechanical and electrical devices, was conceived, designed and supervised by the company's regular operating departments. When it is realized that not less than 300 complete drawings were made and carried to execution by only four departments in less than eight months, and that, too, in addition to the regular operating duties of those departments, the extent of that work can be appreciated.

The new three-phase system of the Brooklyn Edison Co., its great Union plant and its numerous sub-stations, mark a great forward stride in the cheap generation and distribution of electrical energy. With such a system as is now begun the cost of energy will be reduced to a fraction of its former cost, enabling lower rates to be made for current, and thereby extending its field of use. With cheap coal and devices for using it, with private docks and the most economical coal handling machines, with the highest types of engines, generators, distributing and transforming devices, with the possibility of producing electrical energy on such a large scale with an attendance of six men, who can conceive of a more perfect or economical system? The system is, indeed, a monument to the genius of Edison and Tesla.

THE COMPANY'S OFFICERS.—CONCLUSION.

We might go on indefinitely dealing with the innumerable details which go to make up the sum of the business of a company such as that under consideration; but that would lead us too far. Enough has been said and shown, however, to indicate the vast extent of the ramifications and the utility of such an organization, which comes in daily touch with thousands of citizens, many of whose work and welfare depend upon the conscientious fulfillment of the company's obligations. It is this latter feature which, perhaps as much as any other, has given the Brooklyn Edison Co. such a firm hold on public confidence,—that powerful lever for the lack of which no other merits, however great, can make up.

That the work of the company is entrusted to good hands a glance at the names of its officers will make evident. These

are: President, Ethan Allen Doty; vice-president, Edwin Packard; secretary and treasurer, Royal C. Peabody. Board of Directors: Frank L. Babbott, E. Le Grand Beers, Chas. E. Crowell, Julian T. Fairchild, C. N. Hoagland, Darwin R. James, J. G. Jenkins, Martin Joost, Lowell M. Palmer, George Foster Peabody and George H. Southard. Counsel, Frank Harvey Field. Throughout the entire history of the company, from the day of its first inception to the present time, no one has done more to make it a financial success than its secretary and treasurer, Mr. Royal C. Peabody.

Where so much depends upon individual effort and intelligence as is the case in the technical operation of a great current distributing system, it seems almost invidious to single out for special mention any particular individual; but we feel certain that no one in any way connected with the Brooklyn Edison Co. will take umbrage at the mention of the name of the general superintendent, Mr. W. S. Barstow. Risen from the ranks, Mr. Barstow has by his untiring energy, technical ability and rare good judgment gained the fullest confidence of the management of the company, a confidence, by the way, expressed in a most substantial manner on more than one occasion. But more than that, Mr. Barstow has gained the respect and absolute loyalty of all who have the good fortune to labor under his guidance. And in closing we must also tender to Mr. Barstow our most sincere thanks for the great aid extended to us in the preparation of this article.

Public Control, Ownership or Operation of Municipal Franchises?—I.

With Special References to Electric Lighting.*

By R. R. BOWKER,

(Vice-President and General Manager New York Edison Co.)

A MODERN municipality is at once a small state or body politic, and a great corporation or co-operative business. In emphasizing its functions as a business, its limitations as a government must be not less emphasized. If that government is best which governs least, the public should not undertake what private enterprise can do as well. The "government of the people, by the people and for the people" of Lincoln, truest of Democrats, meant a Democratic republic, not a Populistic Socialism. If the trend of the municipalization of industries makes toward Socialism in the State, there is reason for caution.

It is recognized by most thinkers that the social increment belongs to the people. The public, and not private interests, should benefit from the increased values directly caused by the growth of a great city. This does not involve Socialism or the municipalization of industries. It does demand that franchises should not go out of the people's hands without limits as to time, safeguards as to price and adequate power of control.

DEVELOPMENT OF MUNICIPAL INDUSTRIES.

The private or toll road, the well or spring, the private cistern, the tallow dip or oil lamp develop in a modern city into great public needs which can be handled only in an organized way. Among the facilities answering to such needs are streets, sewers, the supply of pure water for drinking and for steam, and of salt or other water for flushing and for fire use, lighting by gas or electricity, telegraph and telephone communication, the supply of power through conduits, street transportation—surface, elevated or underground—pneumatic tubes and postal, messenger or parcels service.

Good roads, it is conceded, must be provided by the commonwealth, as also sewerage; water supply is usually, though not always, considered a municipal function; lighting, communication and transportation are on debatable ground; there are few in this country who approve public bakeries or storehouses, although bread is a necessity of life. Somewhere within this range is the point where Democracy becomes Socialism. It is important to limit the function of the municipality at that point, and not to be misled by the phrase that "a city is a business corporation."

There is no longer any question of the legal right of a municipality in these days to enter almost any field of public supply. Practice has made abundant precedent, and repeated decisions of the courts, culminating in the Rapid Transit decision of the New York Court of Appeals, has settled beyond doubt the legal right of municipalities to invest in and operate what may be called municipal industries. Indeed, so far has practice gone, as in actual cases where electric lighting has been supplied to private consumers below cost at the expense of taxpayers in general, that it is difficult to apply the limiting decision of the United States Supreme Court in the Topeka case that "there can be no lawful tax which is not laid for public purposes." The real limits of municipal activity must be found in an alert and wholesome public opinion which will prevent steps that lead by easy reaches into Socialistic enterprises, pure and simple.

NATURE OF MUNICIPAL FRANCHISES.

A municipal franchise is generally understood to mean a freedom or privilege granted by a municipality giving to companies or other private persons the use of public property or facilities, as of the streets, for the supply of conveniences or commodities to its citizens. The phrase has come to mean indeed an industry for which a franchise would be needed, and has been applied even when such an industry is operated by the municipality. Too often a franchise has been a free gift to private persons; but it is now conceded that such privileges should involve adequate return to the public. This may be made either by reduction in price, giving advantages directly to those citizens who are consumers, or through payment to the municipality of taxes, license fees, royalties on output or gross returns, or share of surplus profits, which last is perhaps the best way because it does not increase or tend to keep up price, but does offer to a supply company an inducement both to enterprise and economy. It does not matter to a gas supply company, for instance, whether the price to consumers is $1.25, out of which 25 cents is paid to the city, or is $1 to consumers direct. On the contrary, it does matter to taxpayers, when a municipal corporation operates an industry, whether the price to consumers is made at or below cost. While in case of profit the citizens generally reap the benefit through the municipality, in the case of loss they have to pay their quota, through taxes, for the benefit of those citizens who as consumers have had their supply at less than cost. In private companies this result of miscalculation or bad management falls only on those who as shareholders have deliberately taken risk.

Franchises to supply public needs are often generalized as monopolies, but a distinction should be drawn. The postal service of the government is a monopoly and an artificial monopoly, because the law makes competition a penal offence. At the start the well and the private cistern may exist alongside the general water supply and sewerage system, but, as a town grows into a city the Board of Health must intervene, and water and sewerage become practically monopolies. Railroads, telegraph and telephone lines are not in themselves monopolies (except as the telephone system is founded on exclusive patents), for it is chiefly because of the public value of an extended and centralized system that new or lesser competitors

*This paper is written from the point of view of the economist and citizen, but with the data and experience gained as the executive of the New York Edison Company. To my mind, this should not involve opposition of interests; as he most serves his party who best serves his country, so he most serves the interest of a public-service company who best serves the public. I mention the relationship, however, to forewarn readers of any unintentional bias. It is difficult for any outside the business cited, in an academic discussion, to obtain real bases of comparison.—Reprinted by permission from Municipal Affairs, the Reform Club Quarterly.

have little chance. Lighting is not a monopoly because gas and electricity have oil, as well as each other, for competitors; and an electric company must also compete with private electric plants—which prevents extortionate prices by what economists call substitution use. It is only when the use of the streets is given to one company or private person as against all others, that there exists a real monopoly in such service.

DISTINCTIONS AMONG INDUSTRIES.

The real key to what is usually called a municipal industry is in this fact: As the whole arterial system of the human body radiates from one central supply station, the heart, so the supply of water, gas, electricity, telephone communication, etc., in a great city, to be constructed and operated at best advantage and at least cost, must radiate from one or more central sources of supply, using the streets as arteries. Here competition involves duplication of investment, increased waste, multiplication of operating expenses, in short, economic loss instead of gain. A unified street railway system with its advantages of transfer has the same economic advantage over independent lines. The inevitable trend in all these cases is, therefore, toward consolidation instead of competition. It is often cheaper to throw parallel systems out of use than to continue the waste of double operating. Competition, in such cases, does not act to reduce price, except by the cut-throat competition of rate-cutting, which involves a final loss instead of a public gain. If three gas mains exist where but one is needed, there is three times the investment cost and three times the operating expenses; costs, and therefore prices, are higher; and in the end, usually one system survives, and the other two are dead loss. The limitation of price, therefore, must be brought about, in private operation, not from competition but by the application of sound business principles on the part of those controlling the industries or by the exercise of the power of municipal regulation in connection with the use of the public streets.

A distinction is to be made between the distribution of natural products and the manufacture of artificial products. Water supply is the distribution of a natural product. There is no manufacture, unless pumping and filtration be so considered. The production of gas or electricity is, on the contrary, a most complicated process of manufacture, especially requiring skilled labor and directive ability. Co-operative production has failed more than once where co-operative distribution has succeeded; and here, perhaps, should be one line of division between municipal and private enterprise.

Another distinction is to be drawn between free and commercial service. The streets are free. Sewerage is free. Water supply is partly free and partly paid for in water "rates" or taxes, especially by large consumers, directly according to metered consumption. Street lighting is free, commercial lighting is individually paid for; but each costs less to produce or distribute when combined with the other. Possibly the line of municipalization should be drawn at supplies which are wholly or chiefly free.

A line is sometimes drawn at necessaries of life. Air is a first necessary of life, and the limitation by law of the height of buildings may be required to prevent dangerous fouling of air in the streets and lower stories. Water is a necessary of life and is supplied usually, though not always, by the municipality. Food is always a necessary of life, heat and clothing are necessaries in most climates; nevertheless, these are not considered, except by extreme Socialists, as properly included under municipal functions. Lighting is a convenience, almost, but not quite, a necessary of life. Transportation is a convenience, but scarcely a necessity. It does not seem that this line of division has real bearing.

Clear thinking is most necessary in distinguishing between public control, public ownership and public operation. Public control involves inspection and regulation, but not necessarily ownership or operation. Public ownership may involve the ownership of the distributing system only, for which the public highways must be used, or of the manufacturing plant also—a distinction most important, though seldom emphasized. Public operation means the actual administration, as a productive business, of both manufacture and distribution. It is important to keep these distinctions in mind in considering the status in respect to public service in the great cities of the world.

City Lighting at Atlanta, Ga.

Mr. H. M. Atkinson, president of the Georgia Electric Light Co., of Atlanta, Ga., discussing the present agitation in that city for a municipal plant says:

"We have been making electric lights in the city of Atlanta for seven years and have been studying the question carefully. I have read everything that has been written that I could run across and I have no hesitation in making the broad statement that there is not an electric lighting plant owned by a city in the United States to-day that is furnishing, under similar conditions, anything like as good service for the money that Atlanta is paying.

"I will further state that there is not a single instance in this country, where a city is lighted by its own plant, in which private enterprise would not furnish as good service under similar conditions for 20 per cent. less than it is costing.

"An investigation of the facts will show beyond doubt that the ownership of electric lighting plants by cities in this country is a record of unbroken failure to achieve the results claimed by the advocates of the policy.

"Now, the whole burden of proof is upon the advocates of municipal ownership to show irrefutably that the taxpayers can save money by adopting such a policy."

TELEPHONY AND TELEGRAPHY

Telephone Employees' Dividend in Cincinnati.

Captain George N. Stone, of the Cincinnati Bell Telephone Co., gave the employés of that organization a great surprise. Formerly the Christmas gift of the company has been a gold piece. This year each employé received a dividend upon his salary, as is stated in the following notice printed on the envelope containing the money:

"Employés' Dividend.—By order of the Board of Directors, you are entitled to a dividend, payable from the net earnings of this company, equal to 8 per cent., computed on your salary for the year ending December 31, 1897, for efficient services rendered the City and Suburban Telegraph Association.

"G. N. STONE,
"General Manager."

For example, the young ladies' salaries range from $27 to $50 a month. The company's Christmas gifts, therefore, range from $25.92 to $48 to each employé.

New Telegraph Facilities in Mexico.

The Mexican Telegraph and Cable Company and the Western Union Company have secured a concession from the Mexican government to connect their wires in the United States with the Federal lines at Nogales, Juarez, and Laredo. Through dispatches can thus be sent by government wires to the United States and all points abroad. Official messages to or from the Mexican ministers and consuls in the United States will be transmitted at 50 per cent. discount from the tariff.

The Western Union will pay 15 per cent. of its receipts to the government for the franchise and guarantees that this payment shall be not less than $20,000 gold semi-annually. The cable company also pays the same percentage, guaranteeing at least $10,000 gold semi-annually. The Central and South American Cable is not included in this. The government agrees to send all its foreign dispatches by these two lines.

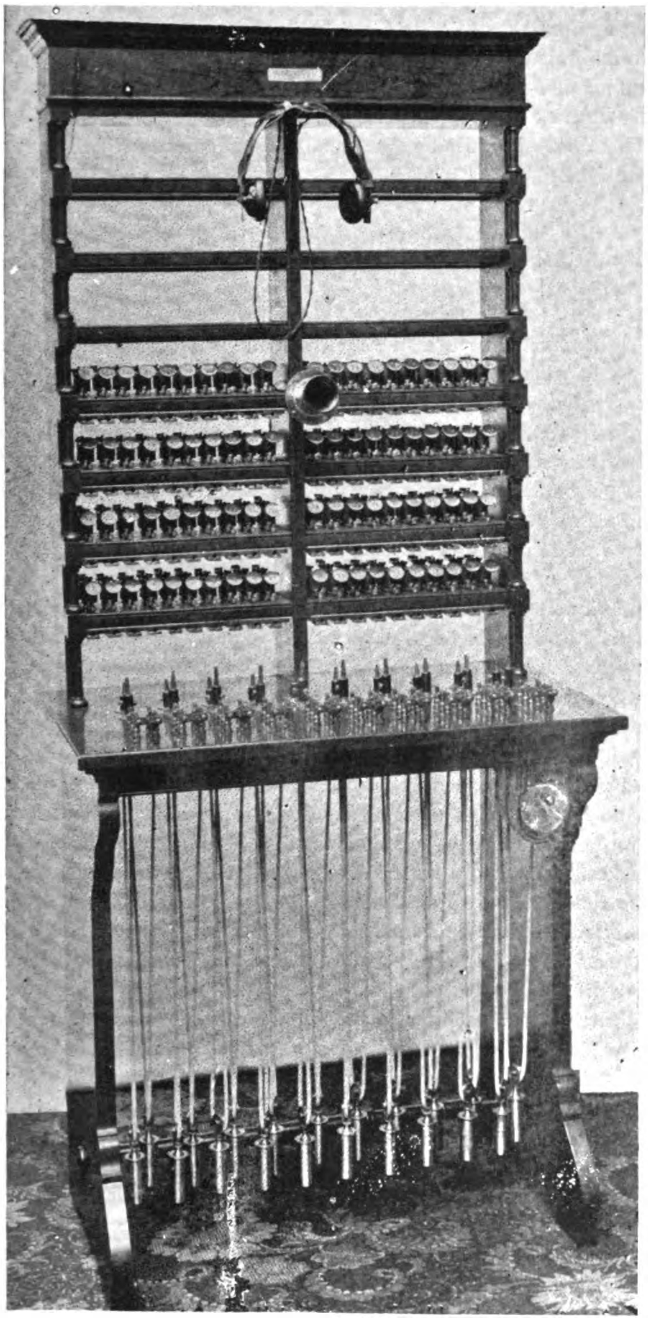
Long Distance Telephony and the Railroads.

S. R. Callaway, president of the Lake Shore & Michigan Southern Railroad Company, says: "For some time railroad men have been trying to find the reason why, in spite of the fact that business is increasing, especially in the transportation of freight the passenger business is languishing.

"After figuring on the matter we have come to the conclusion that the long distance telephone is responsible. Business men are using it more and more and the way it is cutting into our passenger business is a very serious matter to us."

New Switchboard of the Central Telephone and Electric Co., St. Louis.

THE Central Telephone and Electric Co., of St. Louis, Mo., have just perfected a new type of telephone switchboard, claimed by the manufacturers to be the most easily operated of any on the market and also possessing the great advantage of being built on an increase plan, whereby the purchaser may select a cabinet of sufficient capacity to accommodate as many drops as he may consider will possibly be needed and have installed only the number of drops actually needed to start with.



NEW TYPE OF SWITCHBOARD MADE BY CENTRAL TEL. & ELEC. CO., ST. LOUIS.

The drops and spring-jacks are placed on each shelf and the purchaser has as many shelves filled as desired. When increase is in order, he need only send vacant shelves (which are detachable) to the factory and have them filled. After being filled they can be placed in the cabinet by even the most inexperienced person.

Each drop is composed of two coils wound to resistances which equalize the drawing power of both magnets. This is especially desirable where long lines are connected to the switchboard, as it requires but little current to create magnetism in these drops. With the drawing of both magnets, an indicator may be dropped when a call is made over much longer lines than can be successfully attached to the ordinary boards.

All drops are so placed that when the indicators are raised no part of the drops project in front of the spring-jacks. Hence an operator cannot by any accident drop an indicator while connecting cords.

Each spring-jack is directly beneath the indicator of the drop to which it is connected, so that the operator has only to look when a call is made and can plug in and raise the indicator with one hand at the same time.

One of the greatest advantages possessed by this switchboard is in the plug conections. Each set of plugs is composed of a long and a short plug. The short plug is inserted in the spring-jack of the line calling, which connects the subscriber direct to the operator's transmitter and receiver. Gravity batteries are used for the transmitter and therefore no receiver switch hook is necessary to open or close the battery circuit. When the operator is informed of the line wanted, she lets the short plug remain in the spring-jack of subscriber calling and takes the long plug of the same set and inserts it in the spring-jack of the line wanted. This plug automatically cuts out the drop and connects the generator direct to the line, thus leaving absolutely no resistance in the switchboard for the generator current to overcome. On this account calls from switchboard may be made over even longer lines than the same generator would ring over if connected in magneto bell on a telephone.

As soon as the subscriber wanted has been called, the operator throws the knife-switch in front of the plugs to the opposite side, and both cords are then in the same circuit and all parts of the switchboard are cut out, with the exception of one drop, which remains in circuit for the purpose of notifying the operator when the conversation is finished. Any short plug may be used for a listening plug if desired.

The entire space occupied by 100 drops and spring is only 20 inches by 24 inches and a board of 200 drops may be so arranged that one operator could reach each drop and spring-jack without leaving her chair. Each drop is distinct and separate from any other drop and as the line wire is connected to the binding post in the rear of each drop, there is no mass of wires connecting various parts of the switchboard.

The cabinets for switchboards are made from seasoned cherry wood, which is highly polished and very elegant in appearance. Each cabinet is furnished with a "Perfection" long distance granular carbon transmitter, mounted in a short nickel-plated adjustable arm, which is attached to the cabinet directly in front of the spot where the operator will sit. Each switchboard is also furnished with either head or hand receiver as desired, a 25,000-ohm generator, a night alarm with switch, a guaranteed lightning arrester, and batteries for operating both transmitter and the night alarm.

The Central Telephone and Electric Co. have just issued a new catalogue of everything needed in telephone business, which also gives a great deal of useful information to any one interested in telephones. A copy of this catalogue will be mailed to any address upon application.

The Hummel Facsimile Telegraph.

According to the New York Herald a trial was made in its office last week over eight miles of wire of the Hummel facsimile telegraph, of which notices have appeared in the newspapers. Mr. E. A. Hummel, who is a jeweler at St. Paul, Minn,. was present and conducted the trial himself. The Herald vouches for the success of the experiment, and says that in 22 minutes Mr. Hummel transmitted over the eight miles of circuit a portrait of Mayor Van Wyck, which it reproduces in its issue of January 2. According to the Herald, one of the long-cherished dreams of the century is now fully and satisfactorily solved. There is nothing like solving a dream, so the New Year opens well, and we extend our congratulations to Mr. Hummel. All that his invention now needs is a real test as to originality and availability.

The Failure of State Ownership of Canals.

JUST at a time when the proposition to have the State undertake a lot of new duties and administer several different kinds of property or industries never before entrusted to it, comes the news of the utter failure of the State of New York to maintain its canals in a fit and proper condition. This year, when the grain-carrying trade has reached tremendous figures, the Erie Canal has fallen off seriously, we believe, in its tonnage, and the boatmen are universally complaining of the fact. Yet at such a time, when the canal is earning least, but should be earning most, the discovery is made that vast expenditures are necessary to preserve the big ditch from utter disintegration. Nor is New York State alone in this embarrassment, for we mentioned last week the like difficulties now to be confronted in the State of Ohio, where the canals are also in the hands of the State government.

Years ago, when the States went in heavily for canalization, the picture of prosperity and profit was a glowing one, and the money to be saved or made by the public purse was counted by the tens of millions. It is exactly the same way to-day in the minds of the advocates of government control of railways and telegraphs or municipal ownership of lighting and street railway plants. But the real facts, the solid facts of years of operation, all point the other way. The State spent $7,500,000 on the Erie Canal to begin with, and has had to go on spending money on all its canals, while the expenditure on the Erie alone, up to the recent work, had reached $50,000,000. These startling figures are not such as to surprise those who know that the 4,500 miles of canal in this country, costing $214,000,000, are nearly all in as bad shape. The abandoned canals are 1,953 miles, if not more, and a very large proportion of the 2,500 miles remaining do not pay expenses.

But, returning to the New York State canals, it may be noted that in 1895 the people voted a bond issue of $9,000,000 to increase the average depth of the canals from seven feet to nine feet. It is now stated that to finish the work and render effective the $9,000,000 another $7,000,000 will be necessary. The facts in the case are said to have been known for some time past, but they have only now leaked out, and great is the public agitation. Moreover, the allegation is made that despite all the expenditures, the canal system of the State is in a terrible condition of decrepitude and ruin, so that many further millions may be required to make the canals play that part in the State's internal economy and commercial supremacy which has been the aim from first to last.

We have no wish to enlarge on this state of affairs, no wish to suggest wrong doing in office. Our own belief is that the immemorial proof of the inability of any State or municipality to administer economically or in an up-to-date manner is quite sufficient to account for the breakdown of the canal system in New York and the fabulous cost of insufficient maintenance. The State should lease the canals or fill them up and pocket the loss.

The Brooklyn Edison Solution of a Great Problem.

IF the electrical historian of the future in surveying the field of electrical work in America from 1885 to the end of 1897 should wish to single out any departures in central station and current distribution practice, he would be obliged to confine himself to the consideration of a number of details of more or less importance, but he would find it difficult to cite an example of what might be termed a distinct new departure. It would be unfair to deny that substantial and valuable improvements had been made in numerous details, but from the time of the introduction of the alternating current at the first period above mentioned there has until recently been no distinguishing mark discernable in the general handling of current within cities. The alternating current deserves the credit of having widened immensely the field of electrical operation; one might go as far even as to maintain that without it the great industry as it stands to-day could claim but a fraction of the victory which it has gained in so short a time. Yet on the other hand it would be rash to assert that the direct current had not more than held its ground in the fierce competition. We make this assertion with due regard to all the circumstances in the case, and more particularly to the present position of the direct current as a means of distribution, as distinguished from transmission. And the factor which has perhaps more than any other aided to bring about this result is the electric motor.

But without seeking further for causes, it must be recognized by many that the days of rabid partisanship of the advocates of the alternating or the continuous current, respectively, are gone, never to return. Practical experience in distribution work, combined with the new types of machinery offered by the manufacturers have gradually led to a modification of the older ideas, and we think it may now be safely asserted that the furnishing of current for extended city areas will be carried out by a combination of the alternating and the direct current—the alternating for transmission to local centers and the direct current for low tension house-to-house distribution.

The credit of pioneering this movement in actual practice is due to the Brooklyn Edison Illuminating Co., whose latest work in this direction is described in this issue. This work marks an epoch in electrical engineering and distribution work in America, and as such we have deemed it worthy of the generous space and elaborate description devoted to it. We feel certain that every central station company having in mind extension of its work, or contemplating reconstruction or proposing the erection of a new station will find it advantageous to study the work now being carried out in Brooklyn. Considering the problem there involved, it seems difficult to con-

ceive of any arrangement or system better adapted to the conditions than that thought out and carried out by Mr. Barstow.

As to the design of the new Union Station, it would be pretty hard to beat that so far as simplicity is concerned,—and simplicity has always been synonymous with efficiency in mechanical and electrical work. The adoption of the three-phase current for transmission purposes will also, we believe, meet with the sanction of those engineers best able to express an opinion in such matters. We cannot too strongly express our gratification, also, at the fact that the entire high tension system of conductors within the populated sections of the city has been placed underground. As to the actual results obtained, the short time during which the new Union Station has been in operation has already demonstrated the wisdom of the step and has placed the Brooklyn Edison Company in a position to carry on its work with facilities second to those of no other electric current distributing company in the world.

We cannot permit this occasion to pass, also, without extending our congratulations to all those whose apparatus, both electrical and mechanical, has made it possible to carry out this truly great work. It speaks volumes indeed for the potential abilities of our electrical and mechanical manufacturing industries, which enable them to meet, on demand, a call for such apparatus as is embodied in the new work of the Brooklyn Edison Co., to whom we also venture to extend our congratulations on the bright future before it, and the courage with which it has pointed out a solution of the great public-service problem—how best to furnish current for all uses over a large city area.

The Possibilities and Limitations of Electric Traction.

UNDER the above title Mr. F. J. Sprague discourses on a favorite topic of his in the January number of the Engineering Magazine, setting forth again, in the light of fuller experience, his opinions as to the field open to electricity in railway work and that closed to it, at least for the present. Mr. Sprague divides transportation lines into six different classes, beginning with street car or surface, city and town lines at one end, and ending with the independent steam lines and inter-connecting systems, the last two handling both freight and passenger service. These various systems are apparently radically different, and the reasons which might make the adoption of electricity advisable in one case would make it prohibitory in another. It goes without saying that some sort of electric traction system on street car lines is considered by Mr. Sprague advisable beyond argument. So also does he consider that method of propulsion the only one for tunnel and elevated railroad work, examples of which are now rapidly multiplying—excepting, of course, the New York elevated system, whose "lamentable inertia" Mr. Sprague deplores. As to the method of operation of such roads, Mr. Sprague shows that as far back as 1887, before the days of Richmond, he advocated the distribution of the motive power to the individual cars constituting a train, so that they can be operated in any combination and from any point of a train. The acceptance by the South Side Elevated Railway of Chicago of his new individual unit system after official test, and his own experience, warrant Mr. Sprague in predicting for this system, radical departure as it is, a future as important as that marked by the advent of the trolley. It suggests to him the further prediction that Chicago will be the Richmond of the new development. Mr. Sprague has been a pretty good prophet in the past, and if he will stand behind his new system in the same way as he did behind the trolley at Richmond, we would not care to give odds to the scoffers. In closing his article, Mr. Sprague tells us that he did not fully realize all the possible results of his multiple unit control system until he had become familiar with a remarkable series of investigations, embracing all the conditions of railway practice, made by Mr. John Lundie, consulting engineer of the Illinois Central Railroad, when considering the possibility of applying electricity to that road's suburban service. The question of acceleration is here paramount, amounting to 40 miles in 20 seconds for an 80-ton train. From a hint thrown out by Mr. Sprague it would seem that the Illinois Central operations will merit the careful attention of both steam and electrical engineers and railway managers. For all the conditions met in suburban work, the multiple unit system of control appears to Mr. Sprague indispensable and he considers the displacement of the steam locomotive, in fact of all locomotives, assured. The consideration of electric trunk railway service Mr. Sprague reserves for subsequent discussion.

Long Telegraph Circuits.

THE improvement even in an elder electrical industry like the telegraph is steady and unremittent. Last year at this time, note was made in our pages of many of the advances in the art. One of the most appreciable gains is in the length of the circuits over which messages are sent unrelayed. The Western Union Telegraph Co., for example, has often worked direct for regular business from New York to San Francisco, 3,300 miles. But we now learn from Mr. A. S. Brown, electrical engineer of the company, that on December 28 they worked direct from New York to Mexico City, a distance of 3,490 miles, and thought nothing of it. Only old telegraphers can fully appreciate all the gains that this simple statement of bare facts carries with it.

This Issue of The Electrical Engineer.

WE may be pardoned for venturing to emphasize the signs of industrial and commercial recovery afforded by the current issue of The Electrical Engineer, with which the New Year is begun auspiciously. In sheer bulk and volume, this number far exceeds any issue previously sent out of The Engineer; and it is probably the largest, most solid issue of an electrical journal ever actually made in this country. Mere size, however, is no criterion, and it is hoped that the contents in scope and value are also worthy the occasion. Of this our readers will judge for themselves, as usual, for if there is any one thing distasteful to self-respecting journals it is to vaunt their own merits. An endeavor has been made, it may, however, be pointed out, to enhance the appearance of the reading pages by a change of typography. In order to give the utmost quantity of reading The Engineer is often printed almost entirely without "leads," and a more open type has therefore been selected, which makes the page more legible, without lessening the amount of matter.

Electric Rapid Transit in New York.

MAYOR VAN WYCK, of the Greater New York, in his initial message to the Municipal Assembly, comes out pretty flatly against underground rapid transit, on the ground that "Reform" and the recent consolidation have overrun the constitutional limit of debt. Something of this kind was to be expected, although the apparent desire of the Metropolitan Traction Co. to carry out the underground plan may serve to redress the balance. When Tammany says the city is running into debt too quickly it must needs be believed, for if there is one thing Tammany abhors it is civic debt and official extravagance. We are glad to note at the same time that Mayor Van Wyck urges on the Elevated Railroad better facilities, including the abolition of coal burning engines and the adoption of electricity. He is right, and of course the change will now come more immediately than last week. We are also glad to note his recommendation that all the surface roads adopt the "most approved motive power." People who say that this remark means compressed air may be observed to wink one eyelid. Of course what the Mayor refers to is electricity.

ELECTRIC TRANSPORTATION

Mr. A. L. Riker's New Electric Victoria.

WE illustrate herewith the very handsome electric vehicle recently built by the Riker Electric Motor Co., for a resident of New York. It carries two passengers, has a child's seat besides, and weighs all told 1,700 pounds. The frame is of 1½-inch steel tubing. The front wheels are 28 inches and the rear 32 inches, and Hartford pneumatic tires of 2½ inches diameter are employed. The usual pivotal steering already described in Mr. Riker's other carriages is used.

The Riker iron-clad motor, 1½ k. w., weighs 142 pounds and is geared to the axle by a spur gear nine to one.

The battery, composed of 40 Willard cells, which weighs 800 pounds, has a capacity of 100 ampere hours at a five-hour discharge rate, and can be recharged in three hours.

THE NEW RIKER ELECTRIC VICTORIA.

The vehicle is controlled from the seat, like the trap already described in our pages, except that the controller handle is between the two passengers and is operated by the right hand, while the bell is operated by a push button fixed in the end of the steering handle.

Mr. Riker reports that his victoria has been run 1,200 miles around New York City.

The Riker Co. are now building, on order, four traps, three doctor's buggies, two delivery wagons and a brougham and expect a large electric carriage development this year.

Electricity on the Brooklyn Bridge.

The Brooklyn Bridge trustees in their report just out say: "During the past year 45,542,627 passengers were carried over the railway, being a larger number than in any previous year of its operation. It has been in service a term of about 14 3-16 years; during this period 480,692,936 passengers have been carried. Referring to the two means of hauling trains on the Bridge, by electric motors for switching at the stations and by cable over the main tracks between the stations, it is often pertinently asked why the latter is not entirely replaced by the former, ready and capable for the service, as it has proven to be after continued and satisfactory trial.

"In reply it may be said that in a round trip over the railway —which is transit from one station to the other and back again —a train in surmounting the grades over the structure has to be lifted about 140 feeet; thus, if all the trains in service are attached to a running cable, it involves an expenditure of power but little exceeding that required to haul the same number of trains over a level track, the trains descending nearly or quite balancing those ascending. If electric motors were used for hauling the trains over the main lines, whatever power was expended in surmounting the grades could not in descending be returned or compensated for; as a result there would be a loss of power equivalent to that required in a round trip to lift each train vertically to the extreme height mentioned.

"Also, trains running attached to the cable are separated by fixed and uniform spaces as determined by the wisdom of the superintendent in charge; while, if trains were hauled by independent motors, this spacing would be subject to individual care and judgment. In the first case, collision between the trains running close to each other, as they must during the busy hours, is effectively guarded against; on the other hand, if the movement of each train was controlled solely by its motormen, collision between trains might be frequent and sometimes, perhaps, with appalling results."

NEWS AND NOTES

The Montauk Multiphase Cable—A New Interior Electric Cable.

IT is not often that we are enabled to chronicle a decided departure in the construction of electrical conductors, hence the rareness of such occasions makes an announcement of this kind specially noteworthy, more particularly when the new product is one of undoubted value viewed from both the commercial and the electrical standpoints.

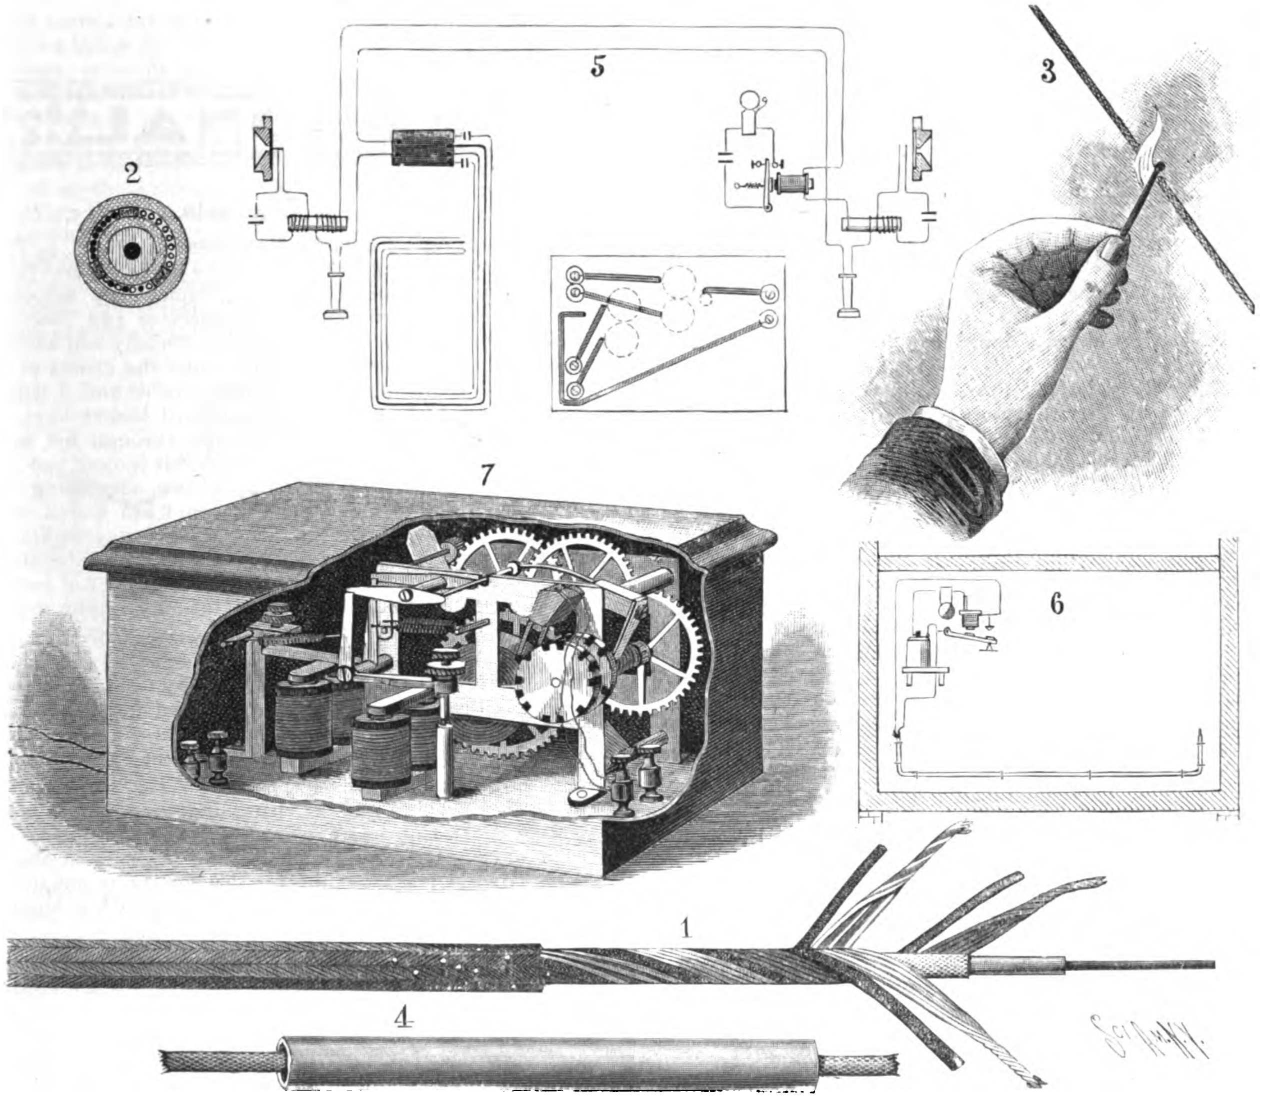
We refer to the new interior electric cables of the Montauk Multiphase Cable Co., of 100 Broadway, at whose offices we were recently afforded full opportunity for testing the merits of this decidedly ingenious product of the cable maker.

Before describing the cable itself we may premise that the salient feature in the construction of the Montauk "multiphase cable" consists in making every inch of the wire installed an infallible detecting point for the discovery of dangerous heat or flame, combined with the ability to give automatic notification of the same at any desired number of points, thus making the cable continuously thermostatic throughout its entire length.

Combined in the Montauk cable with this protection from loss by fire, are all of the necessary wires for giving every kind of electric service which is needed for all interior electrical installations, whether for electric light or power, fire or burglar alarm, etc.

It is not expected by the owners that this cable is going to do away with any present appliances, but it is believed not only by themselves, but by many of those who have investigated this system, that the additional protection that can be acquired through its use will be many times greater than the combined protection heretofore given. In other words, it is the additional protection which has been sought for by property owners and insurance companies for many years, but until the present time has remained undiscovered.

The construction of the cable is as follows: A solid copper conductor, Fig. 1, is surrounded by a fusible core which is in turn covered with proper insulating materials. On the outer side of the insulation a second, a third and fourth conductor are so placed as to be insulated from each other by like insulating material; all are then protected by a heavy outer covering or insulation such as the installing conditions may require.



THE MONTAUK MULTIPHASE CABLE SYSTEM.
(Showing Method of Operation and Connection with a Telephone Exchange, as Illustrative of Its Operation.)

The outer covering of the conductor, while being ornamental, waterproof or dampproof, is sufficiently strong to withstand considerable mechanical injury. If any part of the conductor is subjected to the flame of an ordinary match or dangerous heat for a few seconds, the fusible core melts and makes contact with the surrounding conductors; an alarm will thus be immediately sounded and by the use of an indicator the precise location of the fire is announced.

By a simple method of connection each station or room can be operated independently of every other station or room in a house or other building and the entire system or any part of it can be tested at any point desired without giving an alarm.

In order to establish the system it is only necessary to place a small battery and indicator in position, connecting the core

with one terminal of the battery and (if a twin conductor cable) the other or exterior conductor to the other battery terminal having the indicator wired in series with the same.

If a building is without a watchman, then the cable takes his place, and is far more efficient, because it would be simply futile to expect that a watchman can be wherever all the danger or fire lines are at the same moment, and yet this is the service performed by the cable, covering, as it does, all "danger lines" at once and at the same time.

In the above we have alluded only to the application of the Montauk multiphase cable as a thermostatic device. But it has other equally important applications. Thus it is specially adapted as a burglar alarm wire in addition to its thermostatic qualities. If, for example, a burglar attempts to cut the wire the very act of cutting short circuits the core and the surrounding conductors for an instant, which is quite sufficient to start the alarm ringing, or if the closed circuit system be employed, the severance of the cable conductors opens the circuit and similarly starts the alarm going.

In order to give the cable an extended sphere of usefulness, the company has devised an excellent system whereby the multiphase cable can be used in conjunction with alarms placed in telephone exchanges, district messenger or fire alarm stations, and without adding in any way to the number of wires now employed in these various services nor in any way interfering with them. This is accomplished by the employment of a controller, such as that illustrated in Fig. 7, shown in connection with a telephone exchange, Fig. 5. The controller is placed at the subscriber's station and is so constructed that it gives three distinct signals indicating "fire," "burglar," or "trouble."

We need hardly point out the additional value with which every telephone or district messenger company might endow its system by the addition of such a simple device in connection with the Montauk cable.

The company have standardized all conductors of this cable as follows: Nos. 12, 14, 16, 18, 20, 22, B. & S. gauge; other standards will be forthcoming as rapidly as conditions of manufacture will permit. These standards are those most used by the trade, and accord in size with those adopted by the chief electric interests now existing.

This cable is not intended to be in any way antagonistic to any vested interests, but auxiliary thereto, and while greatly increasing the volume of electrical work, is also intended to greatly increase the earning capacity of existing plants, without increase of operating or maintenance account; the only cost, in the first instance, being the primary installation by the electrical contractor.

In order that the contractor may estimate intelligently upon the "cabling" of buildings for fire, the company have compiled a "Contractor's Hand Book," based upon fire statistics for the past thirty years. This is so arranged that with it in hand, the contractor has but to refer to any particular classification, where he will find the various causes of fire under that head, and be able to "cableize" the particular installation he may be considering, understandingly. As there are 129 classifications it can readily be seen that a new and very large field for business is open to the electrical worker.

THE STOCK MARKET

The Old Year and the New.

It will be remembered that 1897 did not open very propitiously. It cannot be said that the close was particularly bright, coming, as it did, with a large bank failure in Philadelphia, the collapse of a big safe-making trust corporation, and the failure of one of the biggest bicycle builders. But there was a great brightening up of the prospects of business, a paying up of debts, and an accumulation of wealth largely from the sale of the crops; and the untoward events of December were not symptoms, but more in the nature of echoes of bygone troubles. That business will be better in the year 1898 seems beyond question; that there will be boom and rush is happily open to much doubt. People will be in easy circumstances, but they will not pull in money "hand over fist." The efflux of gold from the Klondike may, however, be large enough to make the times resemble those of previous great gold epochs in their buoyancy, especially if, as predicted, the metal comes out by the ton. Meantime the country has its coat off and is working hard, which is the best guarantee of prosperity that can be asked.

The stock market is waiting and watchful, chiefly concerned to see what Congress will do toward giving greater stability to the currency, combined with reasonable flexibility. During the last week of the year Western Union sold to the extent of 45,071 shares, up to 91¼. General Electric, on sales of 7,880 shares, was up to 34; American Bell Telephone, on small sales, went up to 267.

Copper is quoted at 10.87½ cents; heavy steel rail at $19.

PERSONAL

Mr. E. J. Wessels.

With much regret we note the retirement of Mr. E. J. Wessels from the managing directorship of the Standard Air Brake Co., after three years of active and conspicuously successful association with that concern. The readers of The Electrical Engineer are well aware of the energy, pertinacity and shrewdness with which Mr. Wessels has advocated the claims of the air brake to adoption in the street railway field; and it will be a pleasure to all to know that the Standard brakes have not only become well known in this country through his work, but are now in use all over the world. With tongue and pen, by personal interview and brilliantly clever advertising Mr. Wessels has sought to make his point, and has scored every time. It is to be hoped that Mr. Wessels will stay within the charmed circle of electrical affairs, but the inducements offered in every direction to a man so competent and able are such as to make the electrical field but one opportunity among many.

MR. C. O. BAKER, JR., has just returned from a two months' trip all through the West, the Pacific Slope and the Northwest. He is very much encouraged by what he has seen of conditions there and of revived trade and prosperity. He saw abundant evidence also of Klondike richness, and says he would not be surprised to see gold coming out by the ton this year.

MR. S. M. HAMILL, of the Brush Electric Co., was a visitor in New York City last week, and a welcome caller at The Engineer office. His forecast of lighting business in 1898 is very rosy. He believes that the new incandescents put in will run up into millions, but pins his faith also on a few hundred thousand more arcs—chiefly good old Brush.

MR. HORATIO A. FOSTER is giving a series of popular talks before the Real Estate Exchange, Buffalo, on Niagara power and its applications and possibilities.

SOCIETY & CLUB NOTES

An Important Lecture by Mr. S. D. Greene.

At the College of the City of New York, Lexington avenue and East 23d street, at 8 p. m. on Wednesday, January 12, Mr. S. Dana Greene will deliver a lecture before the New York Electrical Society, which hereafter will hold most of its meetings at the city college, by special permission. Mr. Greene, who has already made valuable contributions to the society's work, has chosen a most interesting and timely topic, viz., "The Relations Between the Customer, the Consulting Engineer and the Electrical Manufacturer." The society cordially invites any one to be present reading this announcement, and welcomes accessions to its large and growing membership.

Improved Robertson-Thompson Indicator.

THE improved Robertson-Thompson indicater, illustrated in the accompanying engraving, Fig. 1, which has just been placed on the market, is unusually heavy, but as a result of most careful experiment this weight is so perfectly distributed that the best results may be attained at speeds far in excess of any met with in actual practice. One of the most serious errors in ordinary indicator work is caused by flexure of the arm which carries the drum, particularly when the cord is carried above or below the instrument. In this manner an error of 10 per cent. is easily possible, particularly if the instrument is being used with a high-pressure spring. For instance, with an 80 spring, it would require a movement of but one-eightieth of an inch to show an error of one pound. In many cases weakness at this point will account for the curious features often noticed at the junction of the admission and steam lines on the diagram. The drum-carrying arm of the improved Robertson-Thompson indicater is so stiff that no error from this cause is possible.

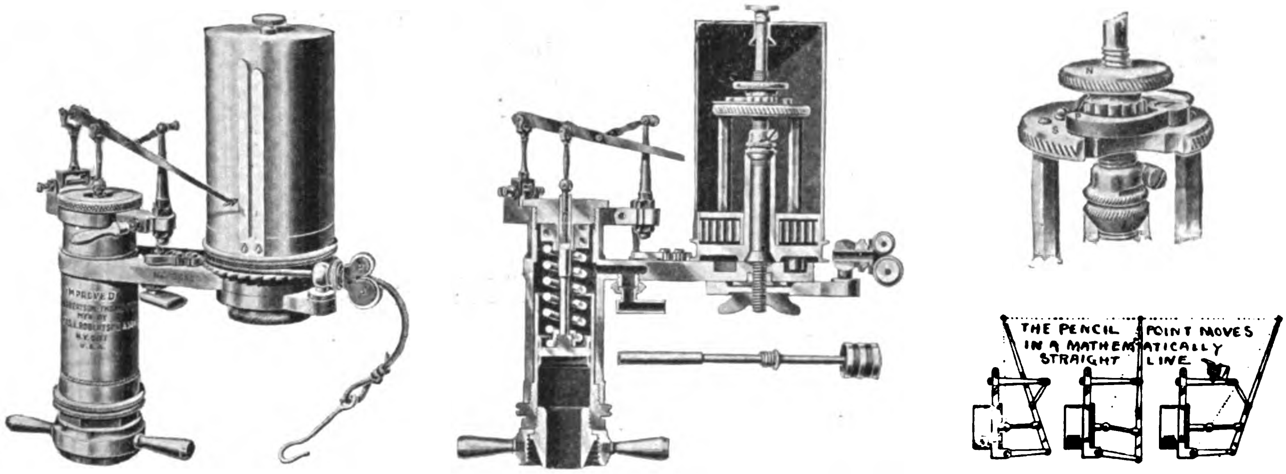
The cylinder is steam jacketed, and by its construction the possibility of the piston being cramped as a result of external strains is precluded. The area of this cylinder is exactly one-half inch, and each spring is suitable for twice the pressure stamped on it; for instance, a 60 spring may be used for a pressure of 120 pounds or less. The coupling is reamed to one-quarter inch area, and with each instrument an extra one-quarter inch piston is furnished, as shown in Fig. 2. With this piston each spring may be used for pressures four times as great as the number stamped thereon, so that with a 60 spring 240 pounds may be safely indicated. This extra piston is of special value for hydraulic and gas engine work.

The pistons are made of steel, but phosphor-bronze will be substituted if preferred. The piston springs are standardized by the most approved testing apparatus, in connection with a mercury column. To guarantee against pressure above the piston a large relief opening has been provided, the outlet being a neat swivel elbow by means of which the "blow" may be discharged in any direction, at the will of the operator. Each instrument is provided with a detent or stop motion.

In Fig. 3 a new device is shown for adjusting the tension of the drum spring. By rotating the knurled head S to the right, the spring may be tightened as much as desired and securely held by pawl P; the ratchet wheel N is securely attached to the shaft by means of a left-hand thread. Thus the tendency of the drum spring is to tighten this ratchet nut more firmly. By pressing the thumb into the recess in the spring winder S the pawl is released, when the tension may be diminished to any desired amount. This ratchet wheel has 16 teeth, which provide for the adjustment of the spring to a nicety. The drum springs are of the clock type, but the spiral form will be furnished if preferred. Cone bearings are provided to take up all wear of the drum steel. The parallel movement is made of tool steel, highly polished and richly blued. All bearings are wide and perfectly fitted.

In Fig. 4 the pencil mechanism is shown in three positions, which will give a perfect idea of the manner in which an absolutely correct straight line is obtained. This movement forms a perfect pantagraph, so that the pencil movement is exactly proportional to that of the piston, the ratio being 5 to 1.

All moving parts are worked down to the lightest weight consistent with durability. For comparison it may be stated that the drum weight is but 1¼ ounces, and the pencil lever 25 grains. By special order the instrument will be fitted with the improved Victor reducing wheel, which comprises the usual cord-feeding device. The manufacturers are James L. Robertson & Sons, No. 204 Fulton street, New York.



FIGS. 1, 2, 3 AND 4—IMPROVED ROBERTSON-THOMSON INDICATOR.

Ferracute Machine Co.

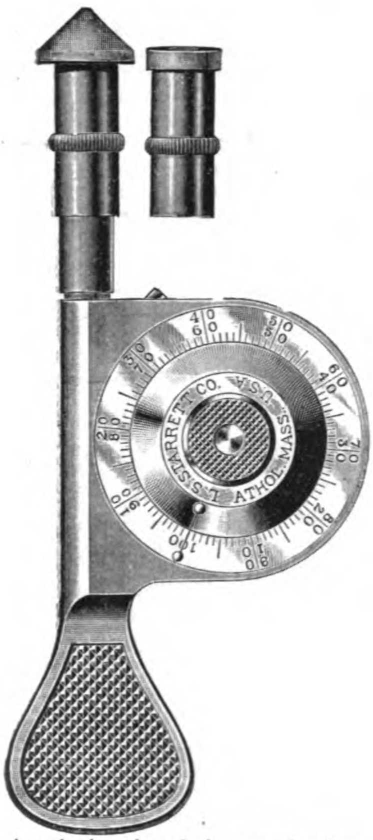
The Ferracute Machine Co., of Bridgeton, N. J., make a specialty of presses and dies for cutting out and notching armature discs, and various other electrical work. They build a full line of large round bed presses for cutting out the discs, and two different styles of presses for notching the discs. The smaller of these cuts 200 notches per minute, and any number of notches in discs varying from 4 inches to 40 inches in diameter. The large machine is a special one for discs above 40 inches up to 12 feet in diameter. They have recently sent out a number of these notching machines to France and other foreign countries; also a number of their other presses weighing from 12,000 to 16,000 pounds each for cutting out discs and other general work. They have also shipped four of these large presses to the Westinghouse Electric Co., of Pittsburg and several other smaller presses to other firms. They have recently enlarged their shops, and are running from 140 to 150 hands. They are just issuing a large poster or circular which they will mail to all parts of the world, and have commenced work on a new catalogue, which will be out in two or three months. They are constantly adding new designs of presses to their already large list, and are producing various improvements so that their presses embody all the most recent improvements in the line of goods they make.

Henry R. Worthington.

Henry R. Worthington are contemplating enlargements of their present storage capacity for castings for their standard sizes of pumps. They now carry in storage from two to three months' supply of all standard castings of six-inch stroke pumps and smaller sizes. It is now proposed to extend this system to standard pumps of much larger sizes.

BURR & HOUSTON CO.—A visit to the foundry of the Burr & Houston Co., 33-39 Franklin street, Brooklyn, N. Y., will show a large force of men at work turning out grey iron castings in large quantities. This firm makes a specialty of these castings for electrical and machinery purposes, etc.

L. S. Starrett Co.'s High Speed Indicator.

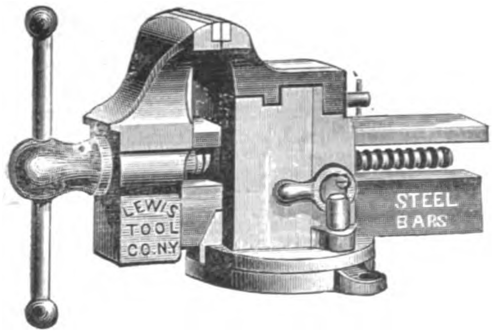


WE referred recently the excellent mechanical tools, tool cutters, etc., made by the L. S. Starrett Co., of Athol, Mass., and at the same time illustrated and described one of their latest micrometers. We now have opportunity to show their No. 104 Starrett high speed indicator, another specialty on which they pride themselves. It is, as will be seen, a very neat, compact and well made piece of apparatus, and the price is very low indeed. This indicator may be run at very high speeds without heating, and this on account of the frictionless bearing against which the inner end of the spindle revolves. The working parts of this instrument are encased, and the dial plate has two rows of figures, reading right or left, as the shaft may run.

The inner plate is frictionally clamped to the revolving gear by a checked wafer head screw. By a pressure and twist with the thumb the plate is loosened, when the o mark may be instantly moved to agree with the starting point, thus saving time revolving the spindle to bring it there. Several new features are under new or pending patents, and a variety of styles or indicators for special work can be had. An important improvement which is now applied to all of their speed indicators, consists in substituting for the hardened steel pointed spindle and split caps, rubber tips for both pointed and centered shafts, which not only remove the jar and run smoothly, but produce a stronger frictional contact between the shaft and the instrument.

The Lewis Patent Vise.

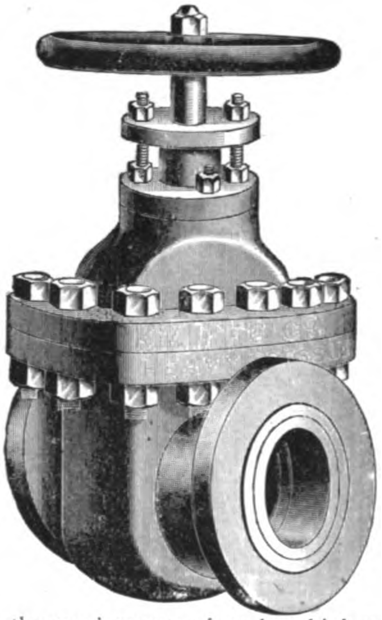
AMONG the many vises which of recent years have been put on the market there are probably few that can boast all the combined features of merit which the Lewis' patent vise embodies. It can readily be seen from the accompanying cut that the slides are two flat bars. The upper bar is mounted above the screen with flat surface horizontal, while the other



THE LEWIS PATENT VISE.

bar is below, with flat surface in perpendicular position to the screw. By this arrangement a perfect resistance is secured for the jaw, against both sidewise and downward strains, and at the same time it gives sufficient elasticity to stand shock of chipping and riveting, an advantage claimed over other parallel vises. The position of the upper bar thoroughly protects the screw, yet it can be readily oiled without removing the slide. The nut is placed at the center, instead of the bottom of the vise, thus adding greatly to pressure and firmness of grip. The winged supports on the nut rest firmly against the body of the vise. The nut fits loosely in the rear end of the socket, thus allowing it to line up with the screw, which prevents it from cutting and obviates the rapid wear complained of in vises having a nut dovetailed in the bottom, liable to spring out of line when under strain. The nut is easily and cheaply renewed when necessary. There are quite a number of other features too numerous to dwell upon in this article. The Lewis Tool Co., 44 Barclay street, New York, are the manufacturers of these vises and have placed their goods with such concerns as the General Electric Co., Pratt & Whitney Co. and many other large concerns throughout the country.

The Kennedy Steam Valves in the Union Edison Station, Brooklyn.



THE great care bestowed on the design and construction of the great new Union Station of the Brooklyn Edison Co., described one of their latest issue, has been carried out to the smallest detail. The steam valves are by no means the smallest consideration in such an installation and in the present instance only the most approved types were employed. Among these were the Kennedy valves, manufactured by the Kennedy Valve Mfg. Co., of 75 John street, New York.

These valves, illustrated in the accompanying engraving, are of their extra heavy pattern, especially designed to fulfill the requirements of modern high pressure steam plants. They are made of the best close grained cast iron, with heavy bronze seats and mountings, and are capable of resisting all strains due to expansion and contraction of water hammer. The bronze seats are very heavy, screwed home to a faced shoulder, which makes a perfect joint, and can be easily removed if necessary. The stems are large in diameter, with deep stuffing boxes, which have an arrangement on the inside whereby they can be repacked without closing the valve or shutting off the steam. These valves are made with inside and outside screw and yoke, with or without by-pass.

LEGAL NOTES

The Stieringer Fixture Litigation.

The N. Y. Law Journal of last week announces the decision of Judge Pryor in the case brought by Luther Stieringer against Richard N. Dyer and George Maitland to secure from them an accounting and payment of Stieringer's share of the income derived since 1888 from the well known Stieringer fixture patents. Up to the time of the action Dyer and Maitland had collected about $120,000, of which they gave Stieringer $15,000. Dyer and Maitland denied that Stieringer was their partner under the contract, but Judge Pryor holds that they were partners and has decreed a dissolution of the firm, an accounting to Stieringer and the appointment of a receiver who shall henceforth manage the business.

THE BRIDGE TROLLEY CARS were set going December 31, the injunctions in the way having been swept aside by the courts of review. Mr. T. L. Johnson rode in the first car across on Friday night.

TRADE NOTES & NOVELTIES

Standard Thermometer & Electric Co.'s Enclosed Alternating Arc Lamp.

WE illustrate herewith the indoor type of the enclosed arc alternating current lamp manufactured by the Standard Thermometer & Electric Co., Peabody, Mass. It is very simple in construction, burns steadily and without noise. It makes a very handsome appearance, and the cover can be finished in any color desired. On 16,000 frequencies the lamp operates direct on secondary circuit at from 100 to 125 volts without transformer or resistance. Where the lamp is desired to operate on 7,200 frequencies, an induction coil is provided and placed in the cover. The maker guarantees for this new improved lamp a life of at least 120 hours, with one set of carbons, at an average current consumption of from 360 to 400 watts. With clear globes a nominal candle power of 1,000 to 1,200 is obtained.

The mechanism of the lamp is held in the cover in such a manner as to confine the vibrations, preventing noise, either from the arc or metallic parts. The clutch of the lamp is provided with a spring, which prevents the carbons from slipping. The trimming device and inner globes, as well as outer globes, are the same on this new type of lamp as on the improved enclosed arc lamps of all other types made by this company. For outdoor service the lamp is provided with a hood and arm. It is shipped from the factory all ready for installation.

Forty Years of Light-giving.

THE firm of I. P. Frink, 551 Pearl street, New York, has for forty consecutive years jealously guarded its reputation for fair dealing, and the superior quality and construction of its reflectors. Successful from the start, it has kept pace with this age of light, improving quality and construction, so that the 1897 reflector would hardly be recognized as a distant relative of the 1857 type.

During this time it has lighted over twenty thousand churches, in nearly every country in the world, and thousands of halls, theatres, armories, schools, hospitals, court houses, stores and public buildings, receiving the first prize, medal and diploma at the World's Fair, Chicago, 1893.

Although advertising "The Great Church Light" extensively, the firm does not confine its efforts to churches only, but has lighted a number of the finest private mansions in the principal cities of America, recently lighting a reception room in New York, in which over one hundred thousand dollars was expended on interior decorations, four thousand of which was for the Frink reflectors for lighting the rooms. The reflectors were heavily plated in gold.

The new Corcoran Art Gallery, Washington, D. C.; the Rhode Island School of Design, Providence, R. I.; Brooklyn Institute of Arts and Sciences, Brooklyn, N. Y.; and Hart Memorial Library, Troy, N. Y., have recently been lighted by Frink reflectors and there are now on hand good orders from Africa, China, England and France, and from churches in nearly every State in the Union, which goes to show the widespread popularity of the Frink reflector.

During the holidays orders are frequently received by telegraph, giving size of room to be lighted, with no previous correspondence. This clearly indicates the esteem in which the firm is held by the general public. Its facilities for turning out good work promptly are more perfect than ever before.

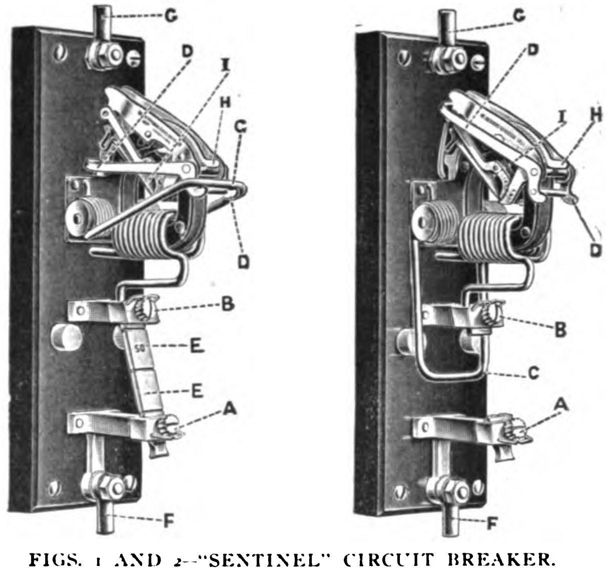
The firm invites correspondence on the subject of lighting and sends its Book of Light free, on request.

New Sentinel Circuit Breaker.

REALIZING the demand for an electro-magnetic device to replace fuses and appreciating the danger of substituting "secondary-break" circuit breakers, especially in cases where constant inspection and attention are impracticable, the inventors of the Sentinel electric circuit breakers have succeeded in perfecting a device which is absolutely reliable, positive in its action at all times, and which may in all cases replace fuses with entirely satisfactory results, requiring only an annual inspection.

The various sizes of the type herewith described are adapted to the protection of circuits of from 6 to 200 amperes, alternating or direct current, at any voltage up to 250, and are furnished in single pole, double pole or triple pole, with either front or back connections.

Referring to Figs. 1 and 2, the main terminals are at F and G, part of the circuit being composed of the metal bar EE, which is made of a brittle, non-arcing alloy. Upon the discharge of the circuit breaker the spring C breaks out the sections EE of the bar as shown in Fig. 2, thus insuring an absolute disruption of the circuit. When setting the circuit breaker with the upper mechanism DD in the position shown in Fig. 2, the spring C is lifted until it raises the trigger H, when the lever D will fall and the spring C remain set. The screws A and B are then loosened and a new bar is inserted and clamped securely by the screws.



FIGS. 1 AND 2—"SENTINEL" CIRCUIT BREAKER.

The following salient features are claimed for these circuit breakers: 1. The circuit once broken can never be closed by the same piece, and the necessary insertion of a new bar insures a perfect connection each time the device is recharged. 2. No moving part of the mechanism is connected with the circuit and once charged it only requires an annual inspection, not being affected by changes of temperature or dampness. 3. The breakers are adapted to both alternating and direct current circuits with a maximum efficiency and accuracy of calibration. Owing to the fact that they have no appreciable

"lag," fuses may be replaced with no increase in the total losses. 4. But few screws are used in the mechanism and these are locked and cannot be loosened by vibrations, neither will vibrations of any nature affect the "set" or discharging point of the breaker. 5. When employed as a protective device for light services it may be operated with perfect satisfaction without the aid of a switch in series with it to finally close the circuit after charging the breaker. In the event of an abnormal load of momentary duration, the breaker may be set and the circuit closed by the insertion of a new bar. When discharged by an abnormal load or short circuit of a more serious nature, the spring C may be set and a new bar inserted until it touches the upper bar holder, when the spring C will be discharged and effectually break the circuit without any danger or injury to the operator.

The Sentinel Electric Co., of Wilmington, Del., who manufacture these circuit breakers, have also perfected a Combined Switch and Circuit Breaker which is specially adapted for the protection of motors furnishing power for machine shops and factories.

G. E. Electro-static Ground Detector.

THE General Electric Company announces a new ground detector to take the place of the transformer and a lamp method, which, although hitherto extensively used, has never given more than a rough indication of the condition of the lines. In the transformer and lamp method of ground detection, the extent of the ground is indicated by a lamp in the secondary circuit of the transformer, but on account of the capacity of the lines the lamp nearly always glows, and the actual condition of the line is difficult to ascertain.

The new device here illustrated is a switchboard instrument. and is similar in construction to that of electro-static voltmeters used in laboratory work. Briefly, it consists of four rigidly fixed sheet metal quadrants, between which is space for the accommodation of a vane carrying an indicating needle. The two lower quadrants are connected internally to the lower binding post for connection to the ground; the two upper to the right and left binding posts respectively for connection to the lines. The vane with its needle is pivoted at the center of the

G. E. ELECTRO-STATIC GROUND DETECTOR.

circle formed by the four quadrants, and is slightly counterweighted to balance the weight of the needle.

In common with all electro-static instruments the operation of this ground detector depends on the tendency of the vane to place itself in the position giving the greatest condenser capacity. If no ground exists on the line the vane lies across the shortest path between the positive and negative quadrants,—the right and left upper quadrants—and the needle points to zero. If, however, either side of the system be grounded, the two lower quadrants cease to be neutral, the system is out of balance, and the vane, taking a new position, deflects the needle to the right or left, indicating the grounded side. A special feature of the construction is that the moving mechanism is insulated and has no electrical connection with either side or with the ground. If it were connected to either side of the line or to the ground, a burn-out might possibly result, but being insulated, the moving mechanism can come into contact with one of the quadrants, without causing any damage. It may be used for temporary connection to any desired line or one for each feeder may be permanently installed.

This electro-static ground detector is constructed for 1,000, 2,000, 5,000 and 10,000 volts, and is set in a black japanned case with cover finished in polished nickel.

Shelby 220-Volt Lamps.

The Shelby Electric Co., of Shelby, O., are out in this issue with the largest advertisement ever made on 220-volt lamps. The remarkable tests which they claim to have made have encouraged them to go in for the specialty of lamps of high voltages, and they are able to furnish lamps of any efficiency from 3.3 watts to 4½ watts per candle power that will show as good life as the average lamps of the same efficiencies in the lower voltages. It will be remembered that they advertised in these pages quite extensively in the early spring time, and the result of this advertising has been so profitable to them that they have been constantly behind their orders ever since. They have now increased facilities for manufacturing and think they will be able to ship promptly any orders sent them. There seems to be a great future ahead for 220-volt work.

Sulphuric Acid for Storage Batteries.

The rapidly increasing demand for storage batteries marks a radical departure from methods heretofore followed in the operation of illuminating and street railway plants, and the demand will increase as the use of accumulators commends itself to owners of large plants.

In the operation of these batteries sulphuric acid is used in large quantities, but much difficulty has been experienced in getting acid of the desired quality. In the past there existed a prejudice against sulphuric acid made from pyrites, which has since been overcome owing to improved methods of manufacture, and to-day, it is said, pyrites acid is manufactured of a quality equal to any acid made from brimstone, and superior to much of the acid made from that material.

The Gasselli Chemical Co., of Cleveland, O., are large manufacturers of sulphuric acid for storage batteries, which is free from all impurities, and prospective buyers of acid or other chemicals for electrical purposes, would do well to correspond with that company.

Owing to their numerous branches, they are in position to supply the trade in any section to the best possible advantage.

Their general office is in Cleveland, O. The New York office is at 63 and 65 Wall street. They have large manufacturing plants at Tremley, N. J.; Cleveland and Chicago, Ill., from any of which the trade can be supplied; also, branch offices and warehouses at Cincinnati, O.; St. Louis, Mo.; Milwaukee, Wis., and St. Paul, Minn.

We learn from them that the demand for this special sulphuric acid for storage batteries has been heavy.

The Monarch Cigar Lamp.

There are evidently other uses to which an incandescent lamp bulb can be put, besides holding a filament and a vacuum. We judge so from the fact that we have enjoyed a fragrant havana which reached us securely packed within the bulb of a "Monarch" candelabra lamp with a removable base to extract the weed. Although we do not know the price of these new lamps, the Western Electrical Supply Co., of St. Louis, may book our order for a couple of barrels of them on the same terms as the sample.

The Ferguson Year Book.

Mr. John W. Ferguson, builder and general contractor, of 253 Broadway, New York, has sent us a beautiful "Year Book for 1898." A page is devoted to every day of the year, allowing of ample room for recording memoranda and engagements The book is bound in Russia leather, with flexible covers, and is a decided ornament to our desk.

Standard Telephone & Electric Co., Madison, Wis.

The Standard Telephone & Electric Co., of Madison, Wis., are securing some excellent business throughout the Northwest. Their business has been of a steady and reliable character from the beginning, and the general satisfaction expressed by purchasers of the Standard apparatus only strengthens its popularity with old and new purchasers alike. The company is one of the most progressive in the competitive telephone field and is constantly putting upon the market new and meritorious devices for telephone exchange work. In the very near future a full line of novel switching apparatus will be introduced, possessing in some particulars many new and striking features. The very successful experience this company has had with its switchboards relieves it from the necessity of putting upon the market anything of an experimental character, as those principles which it has demonstrated to be most appropriate in telephone exchange apparatus will be adhered to in the development of anything of similar character.

Gold's Patent Improved Electric Car Heater.

THE principle of supporting the resistance coils of an electric heater on enameled spirals which has been put in practice by the Gold Street Car Heating Co. has proved such a decided success that the president of the company, Mr. Edward E. Gold, has recently devised and constructed a new form of electric heater which fits into the panel under the seat and the face of which heater is flush with the panel.

The results obtained from very extensive tests made with this new construction of heater have so conclusively proved its superiority that the Gold Company have arranged it to fit into the cases of heaters which are already applied to the cars.

The accompanying illustrations show two views of this new heater. Fig. 1 shows it fitted in and screwed fast to the panel. At the left is shown a three-point regulating switch. In Fig. 2 the front is removed and the interior construction is exposed.

As may be seen, three spiral rods are supported longitudinally by a solid porcelain block at either end. These spirals are made of 5-16-inch steel rod and are thoroughly covered with glass enamel, which is baked on at over 2,000 degs. F. This enamel is of course a perfect insulator and is not affected in the slightest degree by the heat of the resistance wires.

The resistance wire, which is the same composition as heretofore used in the Gold electric heaters, and which is the company's own special composition, having been originally produced by this company especially for heating purposes, is wound into a coil of about half an inch diameter. It is wound under an open tension and when slipped on to the enameled spiral it is in its natural condition and is not spread out under a tension.

When the resistance wire is originally wound on an open pitch there is no tendency for it to lose its original condition nor does its position change in any way.

The new improved Gold electric heater affords the freest circulation of air over the heated surfaces. It will be noticed in Fig. 2 that there is no core to obstruct the passage of the air through the heater. It has always been a predominant point with the Gold Company to have an easy and free circulation of air passing through the heater and as a result this improved construction will produce an equal amount of heat and, it is claimed, use at least 20 per cent. less current in so doing than is usually required.

The construction of this new heater also admits of three gradations of heat on each individual heater. A three-point switch is used in connection with it, the first point of which throws in the botom coil of every heater in the car. The second point cuts out the bottom coil and throws in the upper two coils of every heater, and the third point throws in all three coils in every heater in the car. In this way a perfectly even and uniform temperature is maintained at all times, so no matter at which point the switch is turned, the same amount of heat is being distributed from every heater in the car and no heater or heaters are cut out.

The Gold heater is perfectly insulated in every way and is lined with asbestos and provided with an air space at the back to prevent loss of heat by radiation from the back of the casing. A large number of electric heaters constructed on this principle have been put on the market and in every instance the results obtained have been all that could be desired.

FIG. 1—GOLD PATENT IMPROVED ELECTRIC HEATER.

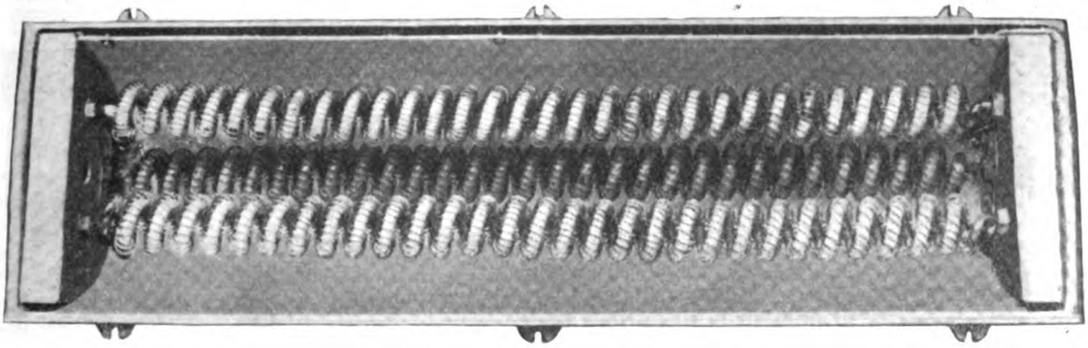


FIG. 2—INTERIOR OF GOLD ELECTRIC HEATER.

MR. GEO. W. PATTERSON has recently been appointed Western representative in charge of the office of the American Circular Loom Co., at 1114 Marquette Building, Chicago. Mr. Patterson is known to the trade through his connections as Western agent for the Gordon-Burnham and Law primary and Ohio storage batteries, and Medbury knife switches and overhead railway material, which he will still represent.

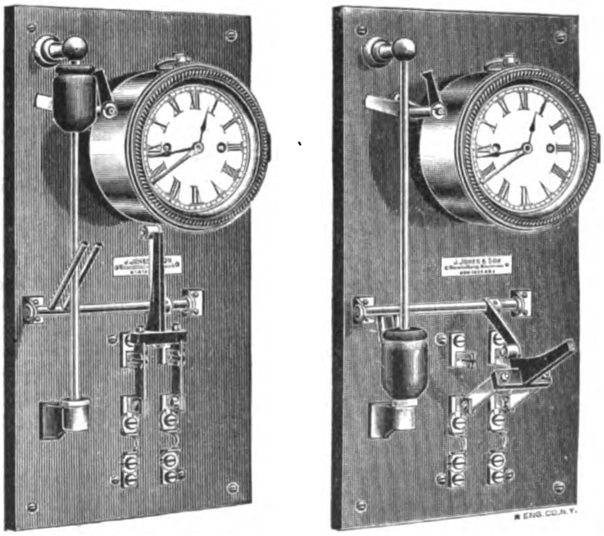
Star Dry Battery.

THE Star Dry Battery Co., 143 Eighth street, New York, are manufacturers of the Star dry battery, which is fast growing into good demand, owing to its superior qualities. The battery is different in construction from others now on the market, and has a high voltage, from 1.5 to 1.6. Its regenerative powers are highly marked and it loses no strength while remaining inactive. The battery can be used for telegraphs, telephones, annunciators, railway signals, electric gas lighting and all open circuit and intermittent work. It is manufactured in the four standard sizes. The Star Dry Battery Co., are the manufacturers also of the New Excelsior Battery, which is exceedingly reasonable in price. They are also manufacturers of the Multiple X-Ray Star Battery for use in conjunction with spark coils.

The Jones Automatic Time Switch.

MESSRS J. JONES & CO., manufacturers and dealers in electrical supplies, New York, have put on the market their new and ingenious time switch, shown in the accompanying illustration. It consists chiefly of a standard 35 ampere fused all copper switch, suitably mounted, so that it can be wired from the back or front, together with a one-day nickel plated clock of good manufacture, all mounted upon a block of enameled slate base ready to be screwed to the wall. The clock is arranged so that at any predetermined time within the 12 hours it will release a weight, which, by falling, opens the switch and circuit.

In the construction of this device Messrs. Jones & Son have succeeded in producing a simple mechanism, thus avoiding all complications in setting or operating. The switch is purely



FIGS. 1 AND 2—JONES AUTOMATIC TIME SWITCH.

mechanical in action, strongly built and has ample electrical capacity in the switch and fusing parts.

It would hardly be necessary to mention in this article the many purposes for which this automatic time switch can be used to good advantage; however, particular attention is called to its great value in reducing the average electric light bill wherever installed.

Among the many uses to which this switch can be applied is in conection with the lighting of show windows during the early part of the night. Then again, there are numerous instances in which electric lighting companies desire to furnish light, but in which it would not pay to send a man to switch off the current.

The low price at which this switch is sold is not the least of its good points.

Messrs. Jones & Co. also make another switch which not only switches off the current, but switches it on again at any predetermined time. One of these latter switches is at present working in connection with the large sign of the North River Savings Bank on 34th street, near 8th avenue, New York.

The Crescent Telephones.

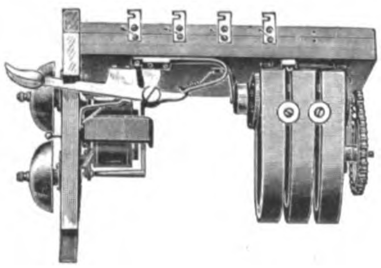
THE Pennsylvania Electric Co., of Marietta, Penn., has just brought out a line of telephone transmitters, the invention of Mr. Paul W. Bossart, manager of the company.

These instruments, which are illustrated in the accompanying engravings, possess a number of novel features, the utility of which will be readily recognized. In the first place they are so designed that they can without any inconvenience be placed

THE CRESCENT TELEPHONES.

in corners or closets, owing to the fact that the mouthpiece can be turned and adjusted at any desired angle both horizontal and vertical, in contradistinction to the present usual style which can only be adjusted vertically. But notwithstanding this universal adjusting facility, the transmitter always remains in a horizontal position, thus preventing packing of the carbon granules.

Another exceedingly valuable feature of the Crescent telephones is the ability which they afford of removing the working parts complete from the body of the cabinet for adjustment or inspection. This is accomplished by opening, at one move-



"CRESCENT" TELEPHONE MAGNETO BELL.

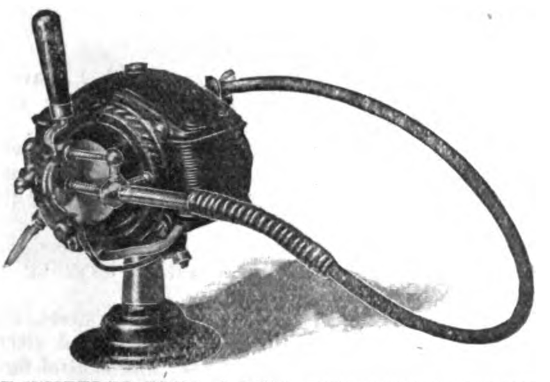
ment, four sliding contacts; these contacts, when closed in position firmly hold the working parts in places.

Besides these important features there are others, all of which are the results of twenty years' experience in telephone work and the Pennsylvania Electric Co. feel that in their Crescent telephones they are offering a first-class instrument in every respect.

WARREN ELECTRIC & SPECIALTY CO., of Warren, O., have issued a large and pretty calendar, in colors. There is a large central figure, which might be taken for a very good likeness of Mrs. Miskel-Hoyt.

The Wheeler Elec. & Mfg. Co.'s Dental Engine.

THE various applications of electricity to dental work have made a considerable tax on the ingenuity and skill of inventors, for it is obvious that in work of such precision and delicacy the apparatus must be well designed and well built to be in any degree successful. Dental drills, for example, when driven by electricity, require very neat adjustments. The Wheeler Electric & Mfg. Co., Dayton, Tenn., are now putting on the market the compact and effective mechanism here shown. This novel electric dental engine depends upon mechanical



THE WHEELER ELEC. & MFG. CO.'S DENTAL ENGINE.

means for the regulation and control of the drills, which can be started, stopped, reversed, etc., quite independently of the number of revolutions of the motor armature. These machines are built to operate on either battery or lighting current, direct or alternating, and are so simple in construction any dentist can handle them easily without having previously to acquire the whole art of electricity. The Wheeler Co. will be glad to receive inquiries and answer correspondence in regard to this or other specialties.

Wagor's "Acme" Guard for Incandescent Lamps.

A cut is shown herewith of the patented "Acme" wire guard for incandescent lamps, made by P. R. Wagor & Co., 275-9 Main street, Springfield, Mass., who make a large line of shades, holders, guards, etc., for electric and other lights. The Acme guard is simple, durable and easy to fix or detach, if desired, and it has gone into very general use. The firm have very good reports from customers and users, and find that their guard business during the past year has been something phenomenal. They will be glad to receive and answer inquiries on the subject from any of our readers.

Hart Switches in 1898.

The Hart & Hegeman Mfg. Co., of Hartford, Conn., manufacturers of the well known Hart snap switches, report business conditions as satisfactory and the outlook for 1898 as bright. Hart switches have been before the electrical public since 1890 and have always borne an enviable reputation for high quality. This company claims that there is a growing appreciation of the fact that a switch has more actual work to perform than any other portion of an electrical circuit and therefore should be selected with care and with due regard to its mechanism and lasting qualities. While competition has caused some manufacturers to lessen the cost of their product at the expense of quality, the motto of the Hart & Hegeman Mfg. Co. has always been "quality first" and whenever it was apparent that an improvement could be made, even at increased cost, the change was promptly adopted. The result of the adoption of this high standard in manufacturing places Hart switches to-day before electrical men in shape that it is hard for the most critical to find fault with; and this care in manufacturing, combined with strictly honorable and courteous business methods, results in the prosperity which it is our pleasure to record. It may not be out of place to add that notwithstanding the great improvements made in Hart switches during 1897 no advances were made in selling prices.

The O. K. Dry Battery.

THE demand for dry batteries for commercial use in preference to various forms of sal-ammoniac have brought out a number of dry batteries, good, bad and indifferent. Among the good ones there is one on the market which has brought to its makers scores of unsolicited testimonial letters and large orders. It is the O. K. battery manufactured by the Non-Polarizing Dry Battery Co., 625 Broadway, New York City. The battery bears every evidence of substantial construction, enabling it to stand the severest test in the way of long life, etc. The materials and chemicals used are of the best and purest, and are said to be combined in a manner radically new and different. Among the many advantages claimed for the O. K. battery are: Polarization reduced to a minimum, freedom from all local action, great recuperative powers, remarkably high voltage and amperage, compactness, indifference to heat or cold, etc. Prof. F. B. Crocker, of Columbia University, recently reported a test made by him on batteries (type B) of the O. K. make. The first of these reports shows that the battery maintained an average of about 1.1 volts and .22 ampere for 88 hours. This is an average of .24 watt or 20 watt hours for the total run. The second test shows the results obtained starting with a current of .55 ampere. In this case the average power was .413 watt for 44 hours, or about 18.2 watt hours. The slight diminution in watt hours was due to the higher rate of discharge. The other three reports show the results obtained

THE O. K. DRY BATTERY.

with rates of discharge, beginning at 1.1 and 2 amperes and a dead short circuit, respectively. The first of these shows that 14.52 watt hours are obtained even when the current starts at 1.1 amperes and averages about .7. But the last two reports represent excessive rates of discharge. Even on a short circuit, however, the battery starts at 8.5 amperes and still gives 3 amperes after one hour's run.

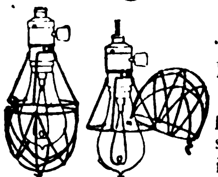
The curves show that the battery would have continued to give current for a considerable time after the tests were stopped, but as the time occupied was 88 hours in one case and 44 in another, it was not feasible to continue any longer. It was evident that the total output would have reached at least 30 watt hours, even at the discharge rate of .2 ampere. At a lower rate of say .1 ampere a still higher output of 35 or 40 watt hours could undoubtedly be obtained. Even after running the battery for 88 hours, and obtaining 20 watt hours from it, it was found that the volts rose to 1.33 after a rest of 48 hours, showing that the battery had recuperated almost to its original voltage, and still contained considerable energy.

The O. K. dry battery is made in five sizes, from 1½ by 4 to 3 by 7 inches. Its e. m. f. is 1.5 volts, and the internal resistances vary between .15 of an ohm and .3 of an ohm.

The Non-Polarizing Dry Battery Co. numbers among its many customers such concerns as N. Y. Central & Hudson R. R. Co., N. Y., N. H. & H. R. R. Co., Pennsylvania R. R. Co., Pullman Palace Car Co., Long Island R. R. Co., Backus Water Motor Co., Otto Gas Engine Co., Pierce Engine Co., Western Electric Co., Chicago Telephone Co., Western Union Telegraph Co., Bell Telephone Co., of Montreal, and Toronto, Canada; Self-Winding Clock Co., Keystone Telephone Co.,

Pittsburg, Pa.; Oregon Telephone Co., Portland, Ore.; Electric Gas Lighting Co., Boston, Mass.; Central Electric Co., National Switch & Signal Co., Easton, Pa.

Inglis "Perfection" Lamp Guard.



We illustrate herewith the improved "Perfection" lamp guard, made by the Wm. Inglis Wire & Iron Works, of Detroit, Mich., and sold by them at remarkably low prices. They are neat and firmly built, and stand wear excellently. The guard opens in such a manner that the incandescent lamp it protects can be handled without detaching the guard from the socket, and it has other similar features of merit. The Inglis Works will be glad to send a sample for inspection. Our cuts show the guard open and closed.

Burnt-Out Lamp Renewal.

The idea of renewing burnt out lamps, originated by promoters of the Lynn Incandescent Lamp Co., seems to be meeting with their most sanguine expectations. Their business has developed into one of considerable proportions and they were again favored this week with an order from their first customer. They have established offices in New York, Baltimore, Cincinnati, and Chicago. This company will renew lamps to any voltage or candle power up to 32, and to any efficiency desired. They claim that an old lamp with a new filament is in every way equal to a new lamp; and the rapid growth and the increasing popularity in the business seems to demonstrate that they are correct.

Chas. Beseler's Son.

Chas. Beseler's Son, of 218 Centre street, New York City, manufacturer of stereopticons, etc., has recently purchased the entire plant of the defunct firm of Peters, Mantz & Co., of 125 and 127 Worth street, and with their additional machinery and a large number of the most modern machines also purchased, he is now in a position to construct stereopticons and all instruments (scientific, electrical or otherwise) to much greater advantage than hitherto. This firm's name is known all over the world for reliable workmanship and reasonable prices. Intending purchasers would do well to send for illustrated catalogue and price list.

Otis Elevator Push Buttons.

A very ingenious, useful and up to date improvement in the running of their private house elevators has been brought out by Messrs. Otis Bros. & Co., of 54 Park Row, New York City. Briefly stated each hall of the house is provided with a single push button, which, when operated, brings the elevator to the floor at which the passenger waits. Upon arriving, the elevator automatically operates a mechanical door fixture or hall door, which allows the latter to be opened. Otherwise the door is securely locked and cannot be opened from the hall. Electric door contacts are also provided, the object of which is that if, in case, by the merest chance, a door is open on any of the floors leading to the elevator, it would be impossible to start the elevator, owing to the circuit being broken, necessitating first the closing of the door wherever it may be. Push buttons are provided in the elevator and are numbered to correspond with the floors of the house. It is only necessary for a passenger to push a button corresponding with the floor desired to be reached, the elevator thereupon proceeding to the floor, stopping at its destination automatically. An extra push button is also provided in the elevator which enables the operator to stop immediately while in motion, thus enabling the car to proceed in a different direction if change of course is deemed convenient by passenger. It can readily be seen how simple and yet to what degree of effectiveness the push button arrangement in the Otis elevators has been brought, enabling the most inexperienced person to operate a house elevator of the company's make with absolute certainty. A large number are now in operation throughout the country.

WM. E. KLINE & CO., 123 Liberty street, will be pleased to mail their catalogue with prices of their miniature lamps, standard incandescent lamps, sundries, etc., on application.

Partrick, Carter & Wilkins.

One of the best known firms in this country as manufacturers of electrical supplies and domestic electrical specialties are the Partrick & Carter Co., of 125 South Second street, Philadelphia, whose record goes back to the "year one." A change has now been made in the style of the firm, which hereafter will be known as Partrick, Carter & Wilkins. The members of the house under this style are Franklin S. Carter, Chas. M. Wilkins, and E. Ward Wilkins. We trust that under the new flag the old house may add to its long list of victories, through many years to come.

Calendars.

American Electrical Works, Providence, R. I., have favored us with a handsome calendar showing their fine factory in colors. It is an ornamental addition to an office.

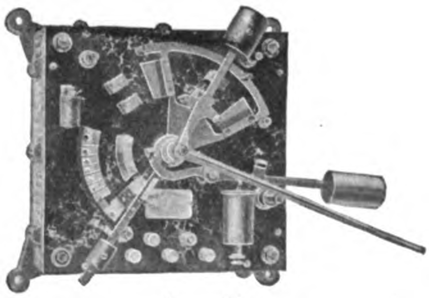
Direct U. S. Cable Co. are out on time as usual with their pad calendar. The supporting card this year is printed in a quiet lavender tint and has a pretty design showing the company's system.

Pope Mfg. Co. favor us with their desk pad calendar, whose daily legends sing the praises of bicycling and the Columbia wheel.

McKenney & Waterbury, of 181 Franklin street, corner of Congress, Boston, manufacturers of gas, oil and electric fixtures, have issued a striking calendar. The central figure is a woman with torch and the legend is: "We light the world."

Mr. W. A. Rosenbaum, the well known patent attorney and electrical expert, Times Building, New York City, has issued an exceedingly pretty calendar, with a peaceful rural scene, entitled "A Cool Retreat."

A New Zimdars & Hunt Automatic Motor Starter.



In the accompanying illustration is shown a new and improved automatic motor starter, which is being introduced by Zimdars & Hunt, 127 Fifth avenue, New York. In this device they believe they have an article which is free from the many sources of trouble so common in apparatus of this class It is operated entirely by gravity, no springs or solenoids being employed. The various operations required to properly start a motor are accomplished by the force of falling weights acting through the movements of a number of levers. The time taken to start a motor can be varied by regulating screws, specially provided for the purpose, on the pivoted air dash pot. This device is entirely automatic in its action, the rate of starting being beyond the control of the operator when once the operating arm has been thrown. Among the advantages claimed for this device are the following: Double pole, double break, main knife switch; knife form of rheostat contacts; absence of springs and solenoids; automatic magnetic release; properly proportioned contact faces and current carrying sections; improved form of pivoted air dash pot; accurate adjustment in all parts, and absolute reliability in action. This device shows evidence of very careful designing, which, supplemented by the high grade of workmanship employed on it, should recommend it to those desiring to start their motors from any distant point.

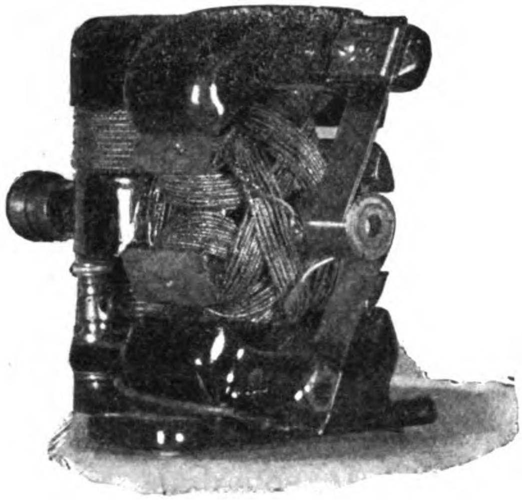
Anchor Electric Company.

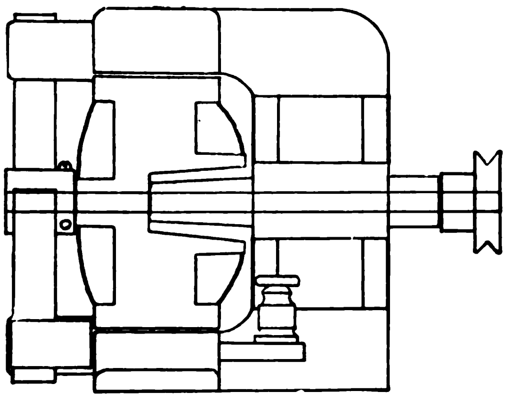
At the regular annual meeting of the Anchor Electric Co., 71 Federal street, Boston, it was voted to increase the capital stock to $100,000. Officers were elected as follows: Norman Marshall, G. O. Proctor, G. H. Proctor, Arthur Howland, directors. G. O. Proctor was elected president; G. H. Proctor, vice-president; Norman Marshall, treasurer; Arthur Howland, secretary. The steadily increasing demand for the Anchor specialties has severely taxed the manufacturing facilities of this well known company, and it has been absolutely necessary to find some way to increase their capacity.

The Kent Battery Motor.

THE Kent Electric Manufacturing Co., of 27 Hermon street, Worcester, Mass., are bringing out a new style of motor designed specially for battery work, and which seems destined to become popular owing to its low cost, efficiency, convenience and durable design.

As will be seen in the accompanying engraving, it differs in several essential points from other battery motors. It has but one bearing, three inches long, reaching nearly through the armature. Thus the shaft is unable to get out of alignment. There is no bearing on the commutator end, thus avoiding the





FIGS. 1 AND 2.—KENT BATTERY MOTOR.

danger of covering the commutator with oil and insulating it from the brushes. The armature is of the drum type, 2½ inches in diameter by 1¼ inches long, and all the iron in the machine is used to advantage for efficiency. It is finished in black enamel with nickel trimmings and rubber cushions are set in the base. The machine may be fastened down by means of two screw holes conveniently located.

The binding posts are placed on each side of the field coil and are entirely out of the way. The pulley is made of cast iron, and is fastened to the shaft by means of a set screw.

The motor is wound for a normal current of six volts, but can be run on from 1 to 12 volts, the power, of course, varying with the voltage. It may be used for any light work requiring less power than a sewing machine. This machine is also wound to be run on a 110-volt incandescent system in series with a lamp.

The "Ideal Circuit Breakers."

A NEW and novel circuit breaker has been put on the market by the Ideal Electric Corporation, of New York. The apparatus is somewhat different from anything yet offered to the public. By referring to the cuts it will be noticed that the movements of the blades, or contact bars, are vertical, having a reciprocating motion up and down. The illustration shows a double pole type, each pole working independently of the other, so that when an overload or short circuit might occur, both blades drop simultaneously. After closing one side of the switch, and the overload or short circuit still existing, in attempting to close the other side, the side already closed will instantly and automatically open. Owing to this arrangement it is practically impossible to close the circuit breaker as long as an abnormal amount of current is passing. The most commanding feature of this switch is that at no time

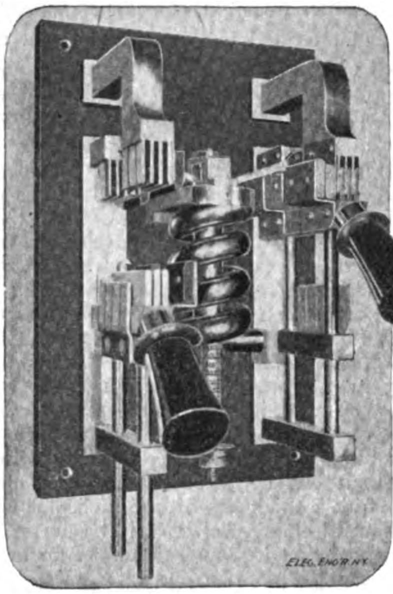


FIG. 1.—"IDEAL" CIRCUIT BREAKER.

during the entire action of opening or closing does it protrude six inches from the face of the switchboard, thereby avoiding the danger so common of striking the operator and injuring him. It is claimed to be the only circuit breaker that a man of ordinary strength can close with rapidity and ease up to 5,000 amperes capacity. All conducting parts are made of hard drawn copper. All parts not made of copper are heavily copper plated, and the entire switch is highly polished and lacquered. It is self-contained and is thereby easily mounted on a switchboard. Only five holes are required to drill for a double pole breaker and no lining up is necessary, as all contact parts are mounted on one copper base, making it impossible to get out of line. Fig. 2 shows a template and all the drilling necessary for a 500 ampere breaker, which avoids the sticking that has compelled the use of heavy springs to throw the blades out of the contact clips. There is only one small compression spring used to operate the Ideal Circuit Breakers, gravity

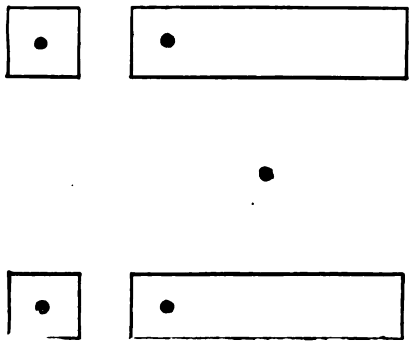

FIG. 2.—TEMPLATE FOR "IDEAL" CIRCUIT BREAKERS.

doing the rest. They are also provided with an evenly divided scale and can be adjusted at from 40 per cent. underload to 50 per cent. overload. Fig. 1 shows a complete double pole circuit breaker; Fig. 2 the template for it. Only three holes need be drilled in the switchboard to mount the breaker. With the Ideal Independent Circuit Breaker no auxiliary switch is necessary, owing to the independent action.

THE DIAMOND ELECTRIC CO., Chicago, Ill., have recently made some important changes in their alternating current meter, and have brought out a new case for their well known transformers. They now are in a position to furnish either the ventilated or the oil type.

Apparatus of the Iron Clad Rheostat Co.

The increase in demand for thoroughly reliable apparatus in the electrical trades has resulted in the development of many concerns who confine themselves exclusivly to certain specialties, and are therefore naturally able to become leaders in their respective lines. The question of proper rheostat control for the fields of dynamos and for the starting and regulating of motors as well as resistances for cauteries, dental lathes and many other applications of the electrical industry has always been considered of special importance to electrical engineers, and builders and users of electrical machinery. Recognizing this principle, the Iron Clad Rheostat Company was formed in the spring of 1895 with the intention of providing the electrical fraternity with the best that could be produced in the rheostat line. Thousands of rheostats, which have given universal satisfaction have been manufactured by them since that time, and an entire reorganization of the manufacturing as well as the business departments of the company now gives them exceptional facilities for prompt shipment of orders, whether of a standard or special nature.

To illustrate in how small a space a 1 h. p. 110-volt motor starter can now be built, it is only necessary to point out that recent exhaustive experiments made by the Iron Clad Rheostat Company have proved conclusively that with their form of construction, it can be placed in an iron clad box five inches square, with a thickness of one inch. This starter was submitted to several eminent electrical engineers, and a result of their test proved that it would stand the normal rated current through the entire rheostat for a period approximately of from 12 to 15 times the rated time limit for which it was designed. The duration of the test covered a period of one hour, and the rheostat was then subjected to double its full rated capacity on one step for four times the rated time limit during which the entire rheostat should be used in circuit. The machine was then subjected to a 1,500-volt alternating e. m. f. between the resistance wire and the iron case without developing any defect in the insulation, which is a remarkable showing for a 110-volt rheostat made without any pretensions as to extra insulation, etc.

The Iron Clad Rheostat Company have recently standardized an entire new line of starters similar to the one described above, and will be pleased to furnish prices, give information, etc., to anybody interested. Their sales are constantly on the increase, and they announce their intention to become the leading builders of rheostats in the United States.

Important Change in the Law as to Foreign Patents.

HOWSON & HOWSON, the patent lawyers, Potter Building, New York City, have issued the following information as to the effect of recent amendments on the same patents when taken out here and abroad:

We beg to call your attention to certain important amendments of the United States Patent Laws, which will go into effect January 1, 1898, under an act of Congress of March 3, 1897:

1. A radical change is made in Section 4887 of the Revised Statutes, affecting the interests of those taking out, or desiring to take out, foreign patents. The section, as revised, reads as follows (the new parts being printed in italics):

"Sec. 4887. No person *otherwise entitled thereto* shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented by the inventor or his legal representatives or assigns in a foreign country, unless the application for said foreign patent was filed more than seven months prior to the filing of the application in this country, in which case no patent shall be granted in this country."

It will be seen that the long standing requirement that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent" will be abolished, so that all patents granted under the new law will run for the full term of 17 years. Furthermore, under the new law, an inventor can apply for his foreign patents without waiting for the allowance of his United States application, or arranging for the issuance of his United States patent. In fact, he can file his foreign applications simultaneously with, or even before the filing of his American application. On the other hand, there has been added a limitation, whose practical effect will be to cause a foreign patentee to forfeit his right to a United States patent, unless he shall file his American application within seven months after the filing of his foreign application.

2. A new defence can be set up to an action for infringement of a patent granted under the new law, namely: "That it (the invention) has been patented or described in some printed publication * * * * more than two years prior to his application for patent therefor." Such two years' prior publication or patenting of an invention will bar the grant of a valid patent for the invention under the new law. (Sec. 4886 and Sec. 4920, R. S.)

3. Under the law as amended, the time within which an applicant for a patent is required to proceed with his application in the Patent Office is reduced from two years to one year after any official action thereon. (Sec. 4894, R. S.)

NOTE.—The act provides that the above-mentioned amendments "shall not apply to any patent granted prior to January 1, 1898, nor to any application filed prior to said date, nor to any patent granted on such an application."

4. The act of March 3, 1897, also put in force a statute of limitation, as follows:

"But in any suit or action brought for the infringement of any patent there shall be no recovery of profits or damages for any infringement committed more than six years before the filing of the bill of complaint or the issuing of the writ in such suit or action, and this provision shall apply to existing causes of action." (Sec. 4921, R. S.)

An Expert Diagnosis of Recent Trade Conditions.

Mr. John A. Walker, vice-president of the Joseph Dixon Crucible Co., has the following to say about business: In 1893 it was a case of business paralysis, in 1894 we had a year of debility, in 1895 the patient partially revived, in 1896 came a relapse, but in 1897 came recovery and the patient took up his bed and walked. The great medicine man was dollar wheat and 30-cent corn, plus poor harvests at this exigency abroad. I saw it myself, for in November I visited Indianapolis, Cincinnati, Chicago, Omaha, Denver, Kansas City, Pueblo and St. Louis, and saw everyone up to his eyes in new business. The consumer at last had money once more, and was spending it.

The industrial triumphs of 1897 are important. In this year the business cloud passed away and another era of prosperity, hopefully of long duration, opened. Export trade was larger in the fruits of the harvest, and particularly in manufactured goods, than in the history of the country. Americans are competing in every market. American motors won the order in London. On a bridge in Holland an American firm was the lowest bidder. American steel rails go regularly to China, Japan and India. A movement is on foot to have the English Parliament pass a law changing the stamp on goods not made in England, stamped "Abroad," instead of the name of the country where they are made. This is an effort on the part of the English lawmakers to obscure the origin of these goods.

For the Dixon Company personally we have shared in the general prosperity. The year has been an agreeable one, the future looks rosy to those who have eyes to see. Perhaps the outlook was never more inviting. Never were there so many roads open to wealth to those who know how to find them.

RILEY BROS.—We are pleased to note that Riley Bros., 16 Beekman street, have received a medal for their excellent exhibit at the American Institute Fair. It bears the inscription, "The Medal of Merit Awarded to Riley Bros., for Stereopticons, Slides and Patent Carrier." Messrs. Riley Bros. manufacture stereopticons, magic lanterns and all accessories and will be glad to mail catalogue, with prices, on application.

MONTGOMERY & CO., the celebrated tool dealers, Fulton street, New York, will have ready about February 1 a new 600 page catalogue, pocket edition, which will be sent to any address in the world on receipt of 25 cents.

The International Health Exposition.

The International Health Exposition to take place in New York City April 25 to May 31 in the Grand Central Palace, Lexington avenue, promises to be a great success. Mr. Charles F. Wingate is to be supervising director and the exhibition will enlist the co-operation of the New York Household Economic Association and kindred organizations. Mr. B. E. Greene is actively connected with the enterprise. Mr. Wingate's plans to differentiate this exhibition from the London "Healtheries" and other sanitary shows and to stimulate public interest in health matters by making a display of the best sanitary apparatus in every line, though nothing displayed will be sold at the building during the fair. In its scope the exposition will comprise an educational congress, where the result of years of study given to sanitary problems by recognized leaders and authorities in their several lines of work may be drawn upon. Prison, military, municipal and residence hygiene are to be demonstrated by the most telling object lessons. There will be an actual sweat shop from the East side, with an actual family at work in it. Against this will be shown a model work room from some new manufactory. There will be the insanitary forecastle from some old battleship by the side of the men's quarters from a recently built cruiser. Actual fittings from some county poorhouse of twenty-five years ago will compare with these places under modern supervision. It is proposed to show to the people of New York a cell from the Tombs with dummy figures placed in its narrow bed to show the wretched housing of prisoners. There will also be exhibits of the improvements in hospitals, public schools and lodging houses.

The classification embraces domestic sanitation with 11 groups; municipal hygiene with 20 groups; food products, health resorts and sanitariums; hygienic literature; sanitary organizations and their work; progress of preventive medicine; military and naval hygiene; animal sanitation; industrial hygiene and fire protection. A series of popular lectures will be provided daily during the exposition, in a separate lecture hall. It is intended to offer special facilities for the pupils of public and private schools, as well as teachers, health inspectors and others interested in health matters. Tickets will be sold at nominal rates to employers of labor to distribute them among their workmen. An effort will also be made to interest the residents of the tenement quarters of the city in the exposition. Mr. Greene has already enlisted excellent support by his good work, and is most sanguine of success.

New Standard Open Circuit Battery.

We illustrate in our advertising pages the New Standard, an open circuit battery, which is now finding a ready sale on the market. Mr. Wm. Roche, 259 Greenwich street, New York, is the manufacturer of this dry battery and has for the past eight years been devoted to the making and perfecting of these goods. During this period he has made over 1,250,000 dry cell batteries, the New Standard being his latest production, and the result of long years of continued experience. Among the many merits to recommend this battery, Mr. Roche calls special attention to its durability, its strength, and its recuperating powers, etc., making it one of the most perfect open circuit batteries ever put on the market.

NEW YORK NOTES.

ROBERT A. KEASBEY, 54 Warren street, New York City, is issuing a beautiful calendar with a picture of a basket of strawberries, and they accompany it with some excellent data on house heating. Magnesia sectional coverings bid fair to be in great demand in 1898, so many new plants are going in.

HENRY R. WORTHINGTON, finding their present enormous output of steam pumps inadequate to properly meet the requirements of their trade are making enlargements which will enable them to increase their output over 30 per cent., especially in pumps of 10-inch stroke.

THREE DIPLOMAS OF MERIT to one concern shows pretty well what the judges of the Tennessee Centennial Exposition (held at Nashville last year) think of the Robertson-Thompson indicator, Lippincott planimeter and Eureka packing. James L. Robertson & Sons, 204 Fulton street, New York, entered these three articles, and inform us they were awarded these prizes. They say if engineers and steam users would send for illustrations and descriptions of these goods, it would not only be of interest but profit.

J. P. WILLIAMS, general agent for the "Paragon" fan, 39-41 Cortlandt street, New York City, has issued a very ingenious 1898 calendar. The backboard has a large picture of the "Paragon" motor, with wire guard, in the natural colors, and the months of the year are printed on the yellow blades of a fan, which can be made to revolve. The whole thing is neatly worked out.

GREATER NEW YORK NIGHT was duly celebrated in this borough and Brooklyn in spite of the wretched weather. There was a parade with floats, singing at the City Hall front, fireworks, and as the New Year chimed a fine display of electric lighting. The show was engineered by the New York Journal. A fine illumination was also given specially on the New York World dome.

MR. W. J. CLARKE, needing facilities for manufacturing, has moved from the office building 120 Liberty street, to the Lexington Building, East 25th street, between Third and Lexington avenues, where there is ample power obtainable for such purposes. Mr. Clarke will continue to handle lamps, etc., while the U. S. Electrical Supply Co. will bring out such novelties as Marconi wireless telegraph, X-ray apparatus, etc.

HERRICK & BURKE.—This well known firm of consulting and designing electrical engineers, of 150 Nassau street, New York City, have given notice that their co-partnership dissolves by limitation. The members of the firm, Messrs. A. B. Herrick and James Burke, will continue to devote themselves individually to the practice of electrical engineering, and their address will be the same as hitherto for both of them.

MR. J. W. GODFREY, with Messrs. Harrington and Olsen, his associates in the handling of the Habirshaw wires and cables at 15 Cortlandt street, celebrated New Year's Eve as usual with a luncheon from 2 until 6 p. m., at those headquarters. It was crowded all the time by an enthusiastic and jolly party of electrical folk, and the afternoon went off most agreeably.

J. P. WILLIAMS, 39 Cortlandt street, New York, is meeting with the same brilliant success on "Paragon" power motors as was experienced last summer with his Paragon fans. The power motors are built in sizes 1-12 to 1 h. p.; are excellently designed and constructed, and fill the bill thoroughly for all work intended. We are informed that orders are coming in from all directions for "Paragon" power motors, as well as orders for special small motors for special uses. Prices, estimates, etc., will be promptly furnished to any concern interested in the purchase of these goods.

BURHORN & GRANGER, 136 Liberty street, have issued a neat combination calendar and thermometer, with mounting in red and gold.

AMERICAN ELECTRICAL & MAINTENANCE CO., A. K. Warren, president, and G. Stanmore, general manager, with main offices at 451-3 Greenwich street, New York, have made a most important arrangement with the New York Edison Co. to do all their motor inspection and repair work. Details are given in our advertising pages. The company have splendidly equipped shops on Desbrosses street, and will be glad to show it to visitors, give information or receive inquiries.

AMERICAN STOKER CO., now located in the Garfield Building, Court street, Brooklyn, are now pushing their excellent device with much vigor and success. It has been winning a fine record for prevention of smoke, higher fuel efficiency, economy of labor, absence of repairs, harmony of practice with the best theory, greater cleanliness and many other features. The stoker is in good hands and will be one of the conspicuous steam engineering features of 1898.

NEW ENGLAND NOTES

THE RIVERSIDE WORSTED MILL, of Providence, R. I., is making some extensive improvements in its plant. Among them is the rebuilding of the boiler house, which is being constructed so as to have it absolutely fireproof. The walls are of brick, and the roof will have metal supports with a

tile roofing. Contract for furnishing and erecting the ironwork has been given to the Berlin Iron Bridge Co., of East Berlin, Conn.

CLINTON WIRE CLOTH CO., Clinton, Mass., have the call in the electrical trade for wire cloth and perforated metals. The goods are growing more and more in use for dynamos and motors, for protecting the commutator, etc. Also for rheostats and other electrical uses.

THE EDDY ELECTRIC MANUFACTURING CO., of Windsor, Conn., have just completed one of the busiest years in their career of 16 years of successful manufacture of dynamos and motors, which have established for themselves a splendid reputation all over the country. The management of the company is the same to-day as when they commenced, which speaks volumes in favor of Messrs. Newton and Baird, than whom there are no two more popular or better known business men in the electrical trade. The outlook for 1898 is equally good, as they have on hand a large number of important orders and their factory is now, as it has been for the past four months, working overtime to keep up with the demand. The name of Eddy on a dynamo or motor is synonymous with good workmanship and economy of design and current consumption.

MIANUS ELECTRIC CO., Mianus, Conn., report an unusually large mail order business in telephones, magneto-bells, telephone parts and electrical supplies. They issue an exhaustive catalogue which will be sent to any address if stamp is enclosed.

ALPHEN'S BELT DRESSING, manufactured by William Alphen, Gloucester, Mass., is reported as giving excellent satisfaction in the many places it is now being used.

THE WALLACE BARNES ESTATE, Bristol, Conn., manufacturers of small springs of every description, have closed a most prosperous year and report that prospects for 1898 are excellent for an increased business. This concern has for years been headquarters for small springs, flat or round wire, steel or brass. The W. B. Estate keep constantly in stock a complete assortment of high-grade cold rolled steel ranging from .003 to .049 in thickness. They temper springs at short notice, make ribbon steel to order and enamel and plate springs. The Wallace Barnes Estate solicits samples and will be pleased to make quotations.

F. R. HARRIS, 35 Benedict street, Waterbury, Conn., reports his factory busy with orders which are coming in from all directions. Mr. Harris has long been known as a manufacturer of the best quality spring and electric wire, also fine brass, copper, German silver and phosphor bronze wire. He makes a special alloy wire drawn to order. Correspondence is solicited.

STANLEY INSTRUMENT CO. has been formed at Great Barrington, Mass., with a capital of $75,000. The directors are W. Stanley, C. E. Yerkes, C. R. Huntley, W. H. Brown, P. A. Russell, J. L. Dodge, F. H. Wright, J. B. Beebe, and F. Darlington. For the present the company will build its apparatus in the Stanley shops at Pittsfield. The officers are Frank H. Wright, president; Wm. Stanley, vice-president and engineer, and F. Darlington, manager. A separate factory for the construction of electrical instruments is in contemplation later on.

MESSRS. P. M. REYNOLDS, treasurer, and H. C. Hawks, president, have sold out their interests in the Anchor Electric Co., of Boston. Mr. Reynolds informs us that he has established himself at 63 Equitable Building, that city.

BILLINGS & SPENCER, Hartford, Conn., have recently built for their own use the biggest drop hammer in the world, standing nearly 22 feet high, and the hammer weighing 1½ tons. It is anchored in a solid bed of stone and concrete. The base weighs 90,000 pounds. It is useful for making such articles as heavy sprocket wheels, and is intended to do with one or two blows work that has hitherto taken repeated beats with lighter hammers.

WESTERN NOTES

K. McLENNAN & CO., Marquette Building, Chicago, write as follows: The year with us was an epoch in itself. It marked the change of Gale's commutator compound from a specialty to a staple article; from an article used by a few plants to one of general use, until at the close of the year it is in regular use by nearly every power plant and central station in the United States and Canada, and to be found for sale in every supply house. In the past year we have established agencies in Sweden, Norway, England, France, Germany, Italy and Japan. The name of Gale is now known to every user of a dynamo or motor. Our expectation for the future is to gather in the few power plants which are not now using our compound.

THE ELECTRIC APPLIANCE CO., Chicago, report that their new issue of General Catalogue No. 12 is now very generally distributed all over the country and is producing very satisfactory results, very few buyers being able to resist the temptation of ordering from such a handsome and useful publication. The Electric Appliance Co. are certainly entitled to all the good that their catalogue may bring them, as its production involved a great amount of work and expense.

PHILADELPHIA NOTES

VALLEE BROS. & CO., 625 Arch street, Philadelphia, have dissolved the old partnership, Garrett A. Vallee and George W. Vallee having purchased the interest of Hiram C. Roberts, the retiring partner. The Messrs. Vallee will continue the business under the familiar style at the old stand and solicit an extension of the favors and patronage already granted them.

PARTRICK, CARTER & WILKINS, of Philadelphia, have issued to their friends their annual New Year souvenir note book, accompanied by a little card of thanks and good wishes. The book is cased in celluloid and has a neat calendar.

ADVERTISERS' HINTS

THE UNITED CORRESPONDENCE SCHOOLS, 154 Fifth avenue, New York, offer special inducements to those enrolling before February 1, 1898.

THE AMERICAN ELECTRIC TELEPHONE CO., Chicago, are offering pay station signs for independent companies at 60 cents each.

FAIRCHILD & SUMNER, 39 Cortlandt street, New York, are the general agents of the Onondaga Dynamo Co., and contract for complete power and lighting equipment.

W. S. HILL ELECTRIC CO., New Bedford, Mass., continue to manufacture and sell their standard switches and switchboards.

THE HART & HEGEMAN MFG. CO., Hartford, Conn., show a great number of their switches of the snap, push-button and flush styles.

HAROLD P. BROWN, 120 Liberty street, New York, publishes some things said by other people regarding his plastic rail-bond and also a table of comparative tests.

THE ELECTRICAL EXCHANGE, 166 South Clinton street, Chicago, advertise electrical apparatus of standard makes which they now have ready for shipment.

J. J. McCABE, 14 Dey street, New York, illustrates his double spindle engine lathe, of which he says: "It is an ideal tool for a repair shop."

RIDGWAY DYNAMO AND ENGINE CO., Ridgway, Pa., show different types of their apparatus and offer to send a handsome catalogue on request.

S. S. WHITE DENTAL MFG. CO., Philadelphia, Pa., advertise the Partz acid gravity battery and refer to its points of merit.

FORT WAYNE ELECTRIC CORP. advertise complete electric equipment for lighting and power.

OTTO GAS ENGINE WORKS, Philadelphia, say they have enjoyed a quarter century of uninterrupted success and have received over 250 medals and diplomas.

RUSSELL ELECTRIC MFG. CO., Providence, R. I., advertise mast arms, hoods and cut-outs.

THE WHEELER REFLECTOR CO., Boston, picture an eclipse of the moon by light from Wheeler reflectors.

THE GOLD STREET CAR HEATING CO., Frankfort and Cliff streets, New York, advertise electric heaters of every description; also the Gold improved sealed jet accelerator system of hot water circulation.

JNO. A. ROEBLING'S SONS CO., Trenton, N. J., say the Columbia rail bond saves coal.

PRATT & WHITNEY CO., Hartford, Conn., advertise milling machines, with hand lever movements in three sizes and with power feed mechanism of 19 styles.

THE BRUSH ELECTRIC CO., Cleveland, O., contrast their apparatus of twenty years ago with their high grade apparatus of to-day.

THE EDDY ELECTRIC MFG. CO., Windsor, Conn., say you make no mistake when you buy the Eddy dynamos and motors, as they are the result of sixteen years manufacturing experience under one management.

CHAS. BESELER'S SON, 218 Centre street, New York, manufactures every accessory for stereopticon work and will be pleased to mail catalogues and circulars to any one interested.

S. MORGAN SMITH, York, Pa., will furnish estimates for complete water power plants and guarantee results.

THE SHELBY ELECTRIC CO., Shelby, O., have a very large "ad." on 220-volt lamps.

THE FUEL ECONOMIZER CO., Matteawan, N. Y., illustrate a 4,000 h. p. plant of economizers at Detroit, Mich., and say their economizers are applied to all types of boilers in the representative electrical plants of the world.

THE GLOBE GAS LIGHT CO., 77 Union street, Boston, Mass., recommend the Globe blow torch for soldering electric wires and other purposes where an intense heat is desired.

WM. ROCHE, 259 Greenwich street, New York, says that a test of the new "Standard" dry battery is sufficient to convince the user that it is of the highest grade.

THE AMERICAN ELECTRICAL MAINTENANCE CO., 451 Greenwich street., New York, publish a fac-simile of a letter sent out by the New York Edison Co., endorsing their methods of inspection and maintenance.

THE SIEMENS & HALSKE ELECTRIC CO., Chicago, illustrate a 500 k. w. Siemens & Halske generator.

H. B. COHO & CO., St. Paul Building, New York, suggest that they be given a trial on switchboards, panel boards and repair work.

McINTOSH, SEYMOUR CO., Auburn, N. Y., advertise engines embodying the best materials and workmanship.

THE KEYSTONE ELECTRIC CO., Erie, Pa., advertise multipolar generators and motors tested in accordance with the most exacting specifications at full and overload, and furnish a report of test with each machine.

THE SAFETY INSULATED WIRE AND CABLE CO., 225 West 28th street, New York, mention six large street railway contracts for lead-encased safety cables which that company has taken.

THE AMERICAN STOKER CO., Dayton, O., have moved their offices to Brooklyn, N. Y. They publish some first-class users' endorsements of the "American" stoker.

THE WALKER CO. mention some advantageous characteristics of their alternators and rotary transformers.

THE PARTRICK & CARTER CO., Philadelphia, have been succeeded by Partrick, Carter and Wilkins.

JAMES LEFFEL & CO., Springfield, O., present some tests on the "Samson" turbine wheels, which should prove a strong argument for their selection.

THE EDISON DECORATIVE AND MINIATURE LAMP DEPT., of the General Electric Co., Harrison, N. J., are headquarters for candelabra, decorative and miniature lamps and X-ray apparatus, and also for sockets and shades.

THE A. B. SEE MFG. CO., Brooklyn, N. Y., simply present a cut of a direct connected electric elevator.

SCHIFF, JORDAN & CO., 232 Greenwich street, New York, have been compelled to increase their manufacturing facilities and have acquired control of the works of Julius Fuchs, Nuernberg, Germany. The products of that well known factory will in the future bear the "Ship" trade mark.

THE CENTRAL ELECTRIC CO., Chicago, are optimistic in their outlook for 1898.

DIAMOND ELECTRIC CO., Chicago, Ill., advertise wattmeters and transformers.

N. W. HENLEY & CO., Nassau street, New York, set forth the merits of some works on electricity.

THE AMERICAN ELECTRICAL HEATER CO., 197 River street, Detroit, Mich., illustrate an electric sadiron, which is but one of the many specialties they manufacture in the heating line.

FRANKLIN H. KALBFLEISH CO., 54 Maiden Lane, New York, make a specialty of battery solutions for telephone work and acids for storage batteries.

E. J. WARING, 136 Liberty street, New York, cites the advantages of the "daylight" electric desk lamp. A large stock is always carried to facilitate promptness in making shipments.

EDWARDS & CO., 144th street and Fourth avenue, New York, advertise interval strike, loud ringing, vibrating bells for schools, fire alarms, street crossings, etc.

ZIMDARS & HUNT, manufacturers of electric light and power specialties, 127 Fifth avenue, New York, advertise their high grade knife switches, switchboards and panel boards and their new improved automatic switches and automatic motor starters. This concern have recently installed a lot of new machinery, which, in addition to the old, enables them to keep up with their rapidly increasing business and to maintain the enviable reputation they have acquired for putting out none but the highest grades of apparatus.

WM. E. KLINE & CO., 121 Liberty street, New York, deal in standard and miniature lamps for all purposes and in all styles in voltages of from ½ to 250.

WM. INGLIS IRON AND WIRE WORKS, Detroit, Mich., are introducing a guard for incandescent lamps which has the novel feature of opening so that the lamp may be removed without disturbing the guard.

THE GOUBERT MFG. CO., 16 Church street, New York, have installed 13,500 h. p. of Goubert feed-water heaters in the stations of the Edison Electric Illuminating Co., of Brooklyn. Their new catalogue is now ready for distribution.

THE C. & G. COOPER CO., Mt. Vernon, O., make a specialty of furnishing complete steam plants of the largest capacity.

THE SENTINEL ELECTRIC CO., Wilmington, Del., are the manufacturers of the "Sentinel" service circuit breakers, and combined switch and circuit breakers for every sort of electrical work. They are operative on direct and alternating circuits.

THE ABENDROTH & ROOT MFG. CO., 28 Cliff street, New York, advertise their standard water tube boilers and Root's spiral riveted pipe for high pressures. This pipe is a double galvanized, spiral riveted, flanged pipe and is found especially useful for exhaust steam, exhaust steam heating, pumping and refrigerating work.

THE CROCKER-WHEELER ELECTRIC CO., 39 Cortlandt street, New York, illustrate the largest printing press ever built, driven by one of their motors, as evidence of their efficiency in driving the heaviest kinds of machinery.

THE ECO MAGNETO CLOCK CO., 620 Atlantic avenue, Boston, Mass., call attention to some facts regarding their watchman's clock which are certainly worth considering. Their catalogue may be had on application, describing, among other things, how the clocks are operated without electric batteries.

THE TRIUMPH ELECTRIC CO., Cincinnati, O., refer to a municipal station equipped with their apparatus, in which the incandescents, arcs and power are on the same circuit.

THE KEYSTONE ELECTRICAL INSTRUMENT CO., Ninth street and Montgomery avenue, Philadelphia, advise the public against accepting any "Keystone" instruments unless accompanied by a certificate duly signed, giving the number of the instrument, its range and date of calibration.

L. S. STARRETT CO., Athol, Mass., have just issued a new edition of their catalogue of fine mechanical tools, milling gear and other cutters. A number of new tools are shown and reduced prices of combination squares are given. It is worth asking for.

THE ELECTRIC STORAGE BATTERY CO., Philadelphia, note two recent orders for the "chloride accumulators" aggregating 7,100 h. p. hours capacity, and the second battery plant of the Brooklyn Edison Co., with a capacity of 14,000 ampere hours.

THE COLUMBIA INCANDESCENT LAMP CO., St. Louis, Mo., claim their lamps to be the very highest in quality and mention some of the "Columbia's" meritorious features.

THE GRASSELLI CHEMICAL CO., Cleveland, O., advertise sulphuric acid for storage batteries, of superior quality and

free from all impurities. Their New York office is at 63 Wall street.

JAS. BONAR & CO., 121 Carnegie Building, Pittsburg, Pa., state that their sales in Pittsburg feed-water heaters for December amounted to 22,500 h. p.

THE FERRACUTE MACHINE CO., Bridgeton, N. J., recommend their presses, dies and other sheet metal tools as specially adapted to electrical work. Their new catalogue describes over 300 kinds of foot and power presses.

THE PENNSYLVANIA ELECTRIC CO., Marietta, Pa., are the manufacturers of the "Crescent" high grade telephone, which they pronounce strictly up to date. They will be pleased to send descriptive matter to those interested.

THE CAHALL SALES DEPARTMENT, Bank of Commerce Building, Pittsburg, publish a list of repeated orders aggregating over 50,000 h. p.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., advertise "O. K." weather-proof wire as one that will wear, and say it costs no more than wire that does not wear.

HENRY R. WORTHINGTON, New York, has installed over 50 of the Worthington self-cooling condensers, ranging in capacity from 200 to 5,000 h. p. each. He also advertises electric pumps for a large variety of uses.

THE BEATTIE ZINC WORKS CO., Reading, Mass., tell why their battery zincs are more economical than those of other makes and also print two testimonials from well known companies.

THE AMERICAN ENGINE CO., Bound Brook, N. J., refer those contemplating the purchase of engines to a long list of satisfied customers who have installed their direct connected plants.

J. JONES & SON, 67 Cortlandt street, New York, illustrate a variety of electrical supplies as some of the things they manufacture and suggest that it pays to buy first handed.

THE ELWELL-PARKER ELECTRIC CO., Cleveland, O., is prepared to completely equip factories, mills, etc., with the necessary generators, motors and all electrical apparatus for efficiently lighting, and driving all the machinery therein.

THE WARREN ELECTRIC & SPECIALTY CO., Warren, O., the anti-trust incandescent lamp manufacturers, thank their friends for having stood by them and wish them all a prosperous '98.

SHAWMUT FUSE WIRE CO., 93 Federal street, Boston, advertise the Cartwright enclosed air-tight fuse to fit the present 500-volt fuse blocks. They will send prices.

WM. H. BRYAN, M. E., and H. H. HUMPHREY, M. S., Turner Building, St. Louis, Mo., may be consulted on all mechanical and electrical engineering matters.

JAS. L. ROBERTSON & SONS, 204 Fulton street, New York, advertise indicators, of which a detailed description may be seen on another page of this issue.

THE GENERAL INCANDESCENT ARC LIGHT CO. emphasize the simplicity and durability of the Bergmann enclosed arc lamps. Their sales office is at 11 Broadway, New York.

WM. E. QUIMBY, 122 Liberty street, New York, make a specialty of direct-connected electric pumps for water works and elevators. His illustrated catalogue may be obtained.

THE BRODIE ELECTRIC CO., Manchester, N. H., call attention to the "Brodie" single-pole primary switch and cut-out for high tension currents for use with transformers and in general outside construction work. It is claimed that it cannot possibly short circuit and is easily put up and wired.

OTIS BROS. & CO., New York, say their elevators embody all the most up-to-date improvements.

THE ROLLINS ENGINE CO., Nashua, N. H., say that the highest economy, absolutely perfect regulation and noiseless operation are characteristics of their engines.

THEO. AUDEL & CO., 63 Fifth avenue, New York, advertise Hawkins' New Catechism of Electricity and present some very convincing testimonials regarding its excellence.

THE STANDARD THERMOMETER & ELECTRIC CO., Peabody, Mass., say the Upton enclosed arc lamp for alternating current is perfectly noiseless, produces steady light, is simple in construction and economical in operation.

THE STAR DRY BATTERY CO., 143 8th street, New York, advertise their batteries and claim they differ in construction from and are superior to all other dry batteries now made.

WHITMAN & COUCH, 196 Summer street, Boston Mass., advertise "the best telephone in the market," and suggest a trial order as a sure means of being convinced.

THE LEWIS TOOL CO., 44 Barclay street, New York, offer something specially good in vises and guarantee every one.

THE C & C ELECTRIC CO., 143 Liberty street, New York, manufacture all the different types of direct current dynamos and motors required in the most approved and exacting practice, of the highest attainable efficiencies and the most substantial construction.

W. F. & JOHN BARNES CO., 28 Ruby street, Rockford, Ill., publish the new prices on different styles of their lathes.

I. P. FRINK, 551 Pearl street, New York, refers to his success of the last forty years in the distribution of light.

THE NEWTON APPLIANCE CO., 120 Liberty street, New York, advertise the "Star" flush switch. Supply houses carry them.

THE CENTRAL TELEPHONE & ELECTRIC CO., 1123 Pine street, St. Louis, illustrate a few of their instruments, of which there are others, and which they say are all winners.

ELECTRIC LIGHTING

Load Factor System of Charging for Electrical Energy.

BY W. S. BARSTOW.

(General Sup't Brooklyn Edison Co.)

THE object of this paper is to call attention to a system of charging for electrical energy (independent of the uses to which it is put) which, while affording a uniform tariff to all customers, will tend to improve the operating load factor of a station and thus gradually reduce the cost of manufacture, which reduction could be followed by a reduction in charges to the customer. It aims to accomplish—

1st. The introduction of a simple tariff, easily understood and appreciated by the public.

2d. A uniform charge to all customers, so based as to apportion to each a just share of the expenses of manufacture.

3d. A gradual improvement of the operating conditions of a station, and consequent gradual reduction in the expenses per unit of energy.

The fixed expenses, herein mentioned, include: Taxes, commissions, executive, engineering and general office expenses; stationery, advertising, legal, etc.; interest on bonds, dividends and surplus, one-half depreciation charges.

The operating expenses, herein mentioned, include: Fuel, oil and waste, labor in station, meter expenses, removal of ashes, street conductors, R. & R.; engines, boilers and piping, R. & R.; house wiring, R. & R.; electrical apparatus, R. & R.; station, R. & R.; one-half depreciation charges.

The sum of these expenses, as mentioned below, forms the total expense, independent of the purpose for which the energy is used. Should the energy be used for incandescent lighting and the company attend to the incandescent repairs and renewals, this item should be added to the final result. Should the energy be used for arc lighting, and the company attend to the arc repairs and renewals, this item should be added to the final result.

EXPLANATION OF THE SYSTEM.

In presenting this method of charging for current, independent of the use to which it is put, the actual existing conditions of a central station company have been closely followed, and to them has been applied a method, which, if adopted, will tend to a continued improvement of such conditions, thereby gradually, without interfering materially with the present rate of earnings, reducing the cost of service to the customer.

The cost of current is made up of two items: Operating expenses, or those usual operating charges which would cease were the operating suddenly stopped. Fixed expenses, or those fixed charges which would continue should the operating be suddenly stopped; in these fixed expenses are included dividends, interest on bonds (both of which, if not paid, would depreciate the capital invested) and half of the depreciation charges, the repairs and renewals being included under operating.

The best conditions of low cost in the generating of energy would be obtained should it be possible to keep the maximum machinery installed in constant operation at its highest efficiency. Should the company operate its maximum machinery every day in the year, but only one-half of the twenty-four hours of each day, the operating expense per unit would show an increase in cost only on account of mechanical inefficiency of the station, which, as the business grows, becomes less and less, but the total fixed expense remaining the same, the fixed expense per unit of current would be doubled. In other words, the proportion between the average load and the maximum load is the earning factor of the station. It is self-evident to all in looking over a load diagram of a central station, that the cost per unit must vary considerably during the day in accordance with the position as to time such unit occupies in the load diagram. The operation of the station has been, and is to this day, studied by a load diagram made up of the current generated during each of the twenty-four hours. In analyzing the expenses of the company, the matter should be studied in the same way, as the expenses of the station are governed by the same conditions as its operation.

In a proper tariff the customer would be charged the operating expenses necessary to produce the unit of current required and a proportion of fixed expenses. In other words, should two customers use the same machinery at different times during a day of twenty-four hours, the corresponding fixed expense on such machinery should be divided between the two, each being charged in addition a common operating cost per unit. If the same machinery is used by three parties they should each stand one-third of these fixed expenses. Thus, each customer jointly pays an equal operating expense and a share of the fixed expense in proportion to the number of hours he uses his machinery in the station.

To be strictly accurate, each day's output of a company should have its corresponding diagram of cost, which will vary with the load factor of that day. As it would require too much space here to do this, there has been taken the average daily output of a company, the maximum of which curve

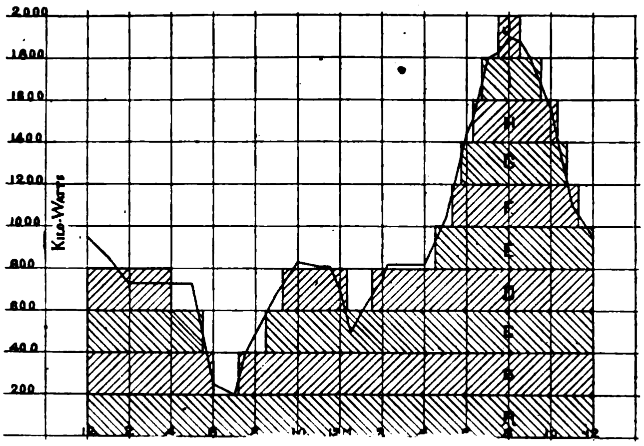

FIG. 1.—AVERAGE LOAD CURVE.

is made up of the average maximums of the year, the load factor of the curve being the average load factor of the station's output for the year. The contents of this diagram (Fig. 1) then, if multiplied by 365, should give us the total yearly output of the station, the maximum showing the average maximum amount of machinery in actual use. For this one average daily diagram of the year might be substituted two average diagrams, one for the six summer months of the year and the other for the six winter months, but, as has been before stated, the number of diagrams and the manner in which they are averaged can be best judged by each station's conditions. And now let us take this average load curve and from it make out a corresponding cost curve; we can then appreciate the variation in the cost of a single unit in accordance with its position in the curve.

First. Take the total fixed expenses of the company and divide by 365, the result being the fixed expenses per day of twenty-four hours.

Second. Apportion these daily fixed expenses to each unit of machinery operated during the daily load, that is, divide the daily fixed expenses by the maximum load of the curve.

Third. Divide the load diagram (Fig. 1) into blocks, each block having for its height a distance measured by the minimum load of the station, and each block having for its base line a distance equal to the time of stopping and starting the unit for the load it takes care of. The reason for this size of block is in order to obtain one high efficiency unit, or one giving the lowest fixed expense (as a company should operate its minimum load during a twenty-four hour period at its highest efficiency). Designate these blocks by letters A,

B, C, D, etc. In examining the load diagram so blocked out it can be seen that block "A" is made up by the operating of machinery continuously throughout the twenty-four hours. Therefore, the hourly fixed expense of this unit of machinery would be the daily fixed expense (mentioned in Second) divided by 24. In other words, should block "A" be made up of a series of twenty-four maximum loads of one hour's dura-

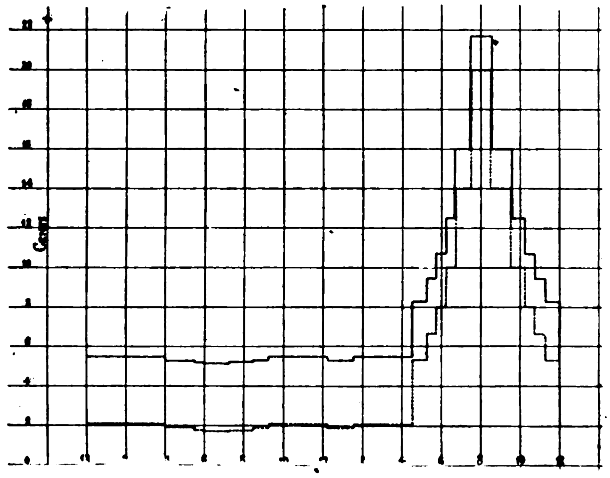

FIG. 2.—AVERAGE EXPENSE CURVE.
Dotted line shows fixed expenses. Solid line shows total expenses.

tion each divided among as many customers, each customer's fixed expense would be one twenty-fourth of the fixed expense of this unit of machinery.

In considering unit "B" we find that it is not operating continuously throughout the twenty-four hours. Therefore, this unit of machinery, during the twenty-three hours that it runs, must stand a larger hourly share of the fixed expenses than if the unit continued throughout the twenty-four hours. In other words, as the earning value of the machinery is measured per hour of unit, "B" would be the total fixed expense of unit "B" divided by twenty-three.

The same rule applies to units, C, D, E, etc., so that:

Fourth. Divide the daily fixed expenses by the hours of operating of each unit and the result will be the hourly fixed expense per unit (depending upon the time such unit is in operation).

If now the hourly fixed expenses, obtained under above directions, for the different portions of the load diagram, are plotted in a manner similar to a load diagram, the resulting curve (dotted line, Fig. 2) will show the fixed expenses per unit throughout the twenty-four hours of the day in accordance with the position that such unit occupies in the load diagram.

In order now to get an operating expense per unit, divide the operating expense of the company by the number of units of current generated throughout the year, making the necessary corrections, due to mechanical efficiency of station at different loads; this correction need not be within twenty-five per cent. of accuracy, because even with this error, the error in total expenses (as the operating expenses are 20 per cent. of the total) would be only 5 per cent., or almost within the accuracy of the customers' meter. If now we add this operating expense per unit to the fixed expense per unit, the result will represent what amount each company should at present pay in order to cover operating and fixed expenses, as mentioned in the first part of this paper.

And now, before proceeding to the practical system best suited to these conditions of expense, let us see what happens as the load factor of the station improves. As the minimum load increases, the next unit working nearer twenty-four hours will cause its expense line to gradually fall to line of lowest expense, until at a load factor of 100 we find the expense per unit throughout the entire day equal to the minimum expense shown in the curve (since all the machinery is operating at its highest efficiency and under the same conditions as in block "A"). The building up of the minimum load or increase of load factor, has the effect of lengthening the time of low rate and also reducing the high rate or reducing the total expense to the customer (Fig. 3), those customers using current only on the maximum load being the last to receive the reduction. Instead of charging customers different rates for current during different hours of the day, as shown by this expense curve, it is proposed to divide the day into two parts instead of one, as it is now done, and during one of these intervals grant a discount, making this net price equivalent to the average low rate, as shown on the expense curve.

To accomplish this end, the Kapp meter device is admirably adapted. This device, in American form, consists of a self-winding clock controlling two dials which are thrown in or out of action at pre-determined times, as shown by expense curve. When used with an Edison meter, it is placed so that the clock controls the shunt circuit of the meter. Thus one meter shunt is continually recording, while the second meter shunt records only at pre-determined times, or the clock switch is so made as to transfer the current from one meter shunt to the other, giving two distinct readings for the different periods of the day. The above readings are, of course, secured without interrupting in any way the main service.

As applied to the mechanical meter, the clock controls, mechanically or electrically, a small clutch, which at pre-determined intervals couples together two separate registering trains. Thus at all times one train is continually recording, and at the desired time the other train is thrown into action, One form of this device is the coupling to the meter shaft first one meter train and then the other, the dials thus recording the current used during the two intervals of the day.

It has been proposed to have the clock introduce into the shunt circuit, at pre-determined times, a resistance which would tend to reduce the speed or rate of recording of the meter, so that the sum of the readings taken by the meter at its normal speed and reduced speed should be recorded on the single dial or single meter bottle. This form of differential meter is open to a very serious objection, as it does not record the current used, and it is almost impossible for a company to make an intelligent contract with a customer with such a device, for at the end of the month there is no way of ascertaining how much current the customer has used at list price, and how much at a discount.

With the Kapp device the form of contract is the same for all customers, the same price being made to all customers on all current used. But a customer using a large quantity of current during the minimum load period of the station, and a small amount during the maximum load of the station, would receive a lower bill than a customer using vice-versa, both customers being on equal basis. This condition of affairs corresponds exactly with the company's expense for the current and cannot but increase the load factor.

Each company must prepare a working load diagram according to the condition of its present tariff, and upon results thus

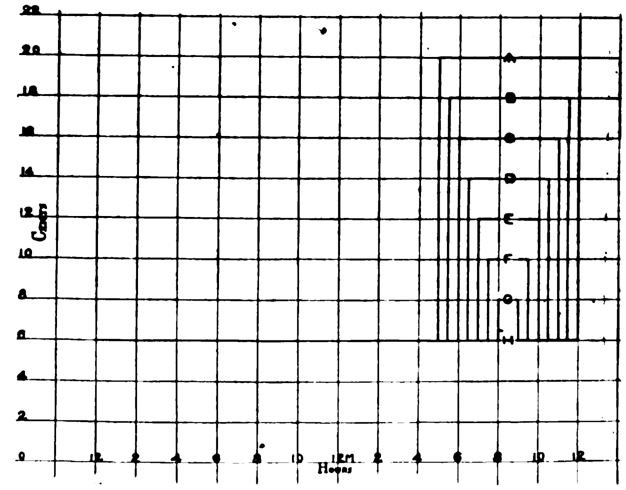

FIG. 3.—TOTAL EXPENSE CURVE.
Effect on total expenses of increase of load factor; i. e., A, load factor, 45 per cent.; B, load factor, 50 per cent.; C, load factor, 55 per cent.; H, load factor, 100 per cent.

obtained, base its net year's charges. In changing over from an old tariff to this new system it will be found, perhaps contrary to expectations, that the net results will be affected but slightly. It will be found that there are many customers whose charges per unit will be increased rather than diminished, and

as it is impracticable to increase these charges, these customers would remain on the old basis until a time when the high rate period would be at such rate and duration that their net bills would be equal to their present net bills, at which time the old contract can then be exchanged for the new one. In this way, by the wish of the customer himself, the system can be gradually changed until all customers are upon an equal basis and form of contract.

The system, thus far, makes no distinction between the large or small customer, each being charged at the same rate. If a company desires to make such distinction, it should be done by granting an extra discount, depending upon the amount of the bill. Thus, throughout the entire system of charging, all customers remain on the same basis.

Sample Contract Clause.—The customer to be charged at a rate of twenty cents (20c.) per kilowatt hour for all electrical energy used between the hours of 5 p. m. and 12 p. m. each day, and to be allowed a discount of 70 per cent. on all electrical energy used during the remaining hours of each day.

CASH DISCOUNTS WILL BE ALLOWED ON

All net bills over $100....................10 per cent.
All net bills over $250....................15 per cent.
All net bills over $500....................20 per cent.

As load factor of plant increases, discount can be made on twenty cents (20c.) and the interval at this rate shortened until the discount becomes equal to discount on remaining hours of the day and the interval becomes zero as will be the case when load factor becomes 100 per cent. Curves in Figs. 1 and 2 should not be confounded; with increase of load factor on Fig. 1 the lowest expenses of Fig. 2 can never be increased.

Multiple Rate Metering.

BY EUSTACE OXLEY.

IT is not probable that "methods of charging for current" is a subject that will now command the same general interest that has heretofore been shown, both in this country and abroad.

The reading public is growing tired of a discussion that has had little result, except the production of a great variety of conflicting opinions. Still, it is hoped that a question of such importance may not be without interest, provided it can be shown that a long step has been taken in the direction of its solution. A new system of applying the double rate method of charging has been employed by a large electric lighting corporation in this country, for some five or six months past. Broadly speaking, the method is well known, but its employment in this instance has been under novel conditions. The marked success which has followed, and the results that have been accomplished in solving problems of much importance to all generating companies, will lend interest to a description of the manner in which these ends have been attained.

A rational and satisfactory system of charging for current must accomplish certain results, all of which are essential, though not in the same degree. Prominent among these are three considerations which cannot well be separated: The first is to reduce the cost of generation, the second to extend the adoption of electric energy for heating, lighting, power and all the uses for which it is so well adapted, and the third to induce all consumers to increase their consumption, economically to themselves and profitably to the generating company. Such a method must have in view the improvement of the load factor of the entire outfit, the mains as well as the generating mechanism.

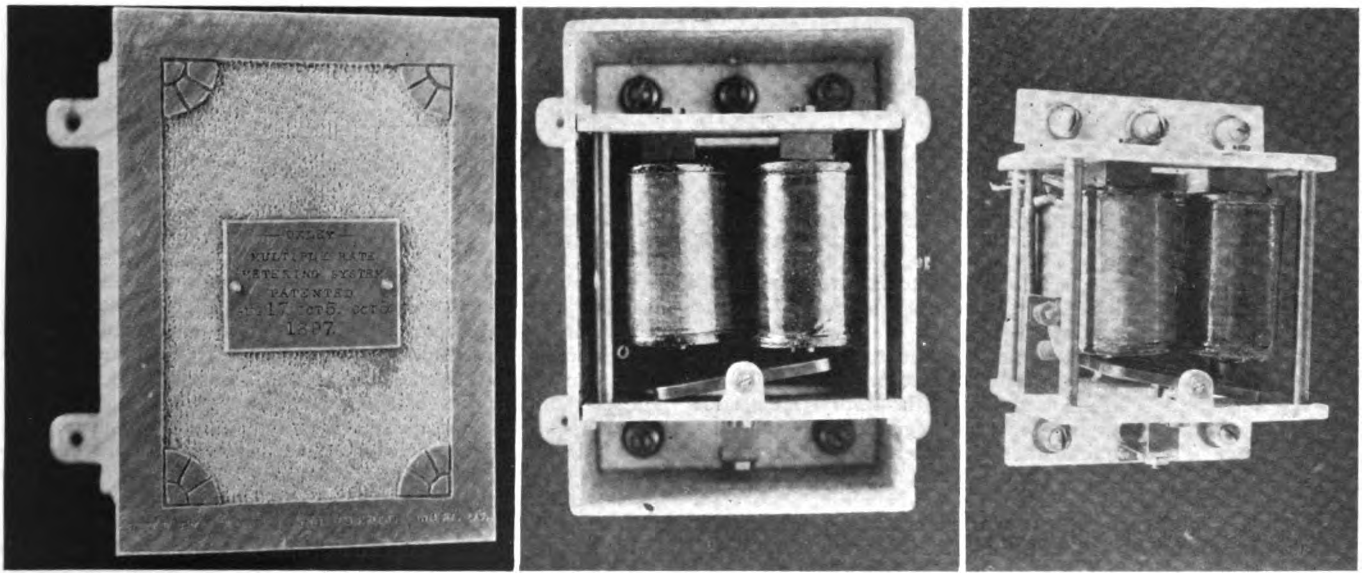
To do this effectively it must hold out strong inducements to all consumers to extend the hours of consumption, and to multiply the purposes for which current is used. It should not discourage an increased demand for current at any hour of the day, but it should not, on the other hand, induce large demands during those hours when the maximum output for lighting occurs. The general aim must be, as Prof. Thomson says, to "smooth out the hills and hollows of the load diagram," and this can only be done properly by bringing the lower parts of the load curve up to the peak as nearly as possible, instead of lowering the peak itself.

Finally, the method must be simple and equitable, to both the company and the consumer. A method that accomplishes all these objects would seem to be as near the ideal as possible. The experience of the past appears to have established a general conviction that the double-rate method, or discounts based upon the time of demand, is best adapted to the main requirements.

It has been widely used in different ways, and is simple and logical. To give consumers a discount, or low rate, during all hours save those in which the peak of the load occurs, and a normal or higher rate during the few hours when the maximum number of lamps will be in use, holds out the strongest inducement to the public to substitute electric energy in place of steam for power, and to employ it for many other purposes.

An increased rate during peak hours does not, in any proper sense, discourage increased demands at that time, and, on the other hand, it does not have any tendency to produce such demands. A reduced rate during the remaining hours, at the lowest figures consistent with the proper interests of the generating company, will act as a powerful inducement to the consumers to use current during those hours.

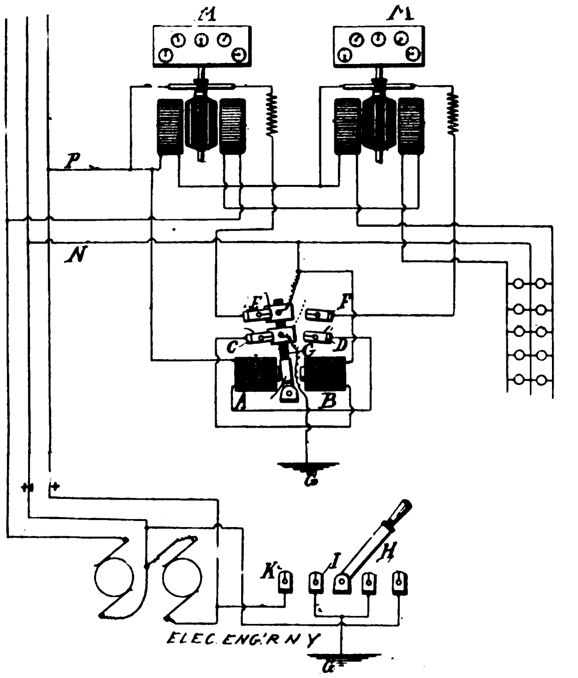
Cooking, heating and many other of the familiar processes of daily life only await the time when their performance by a servant, so safely and cleanly, can be had at a cost which is not prohibitive. The resulting improvement of the load factor, and the increased efficiency of the generating mechanism, will

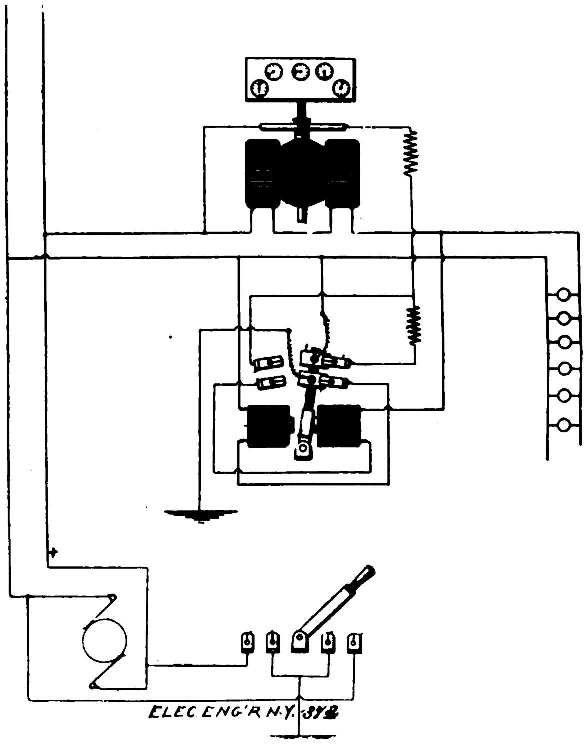


FIGS. 1, 2 AND 3.—THE OXLEY MULTIPLE RATE METER CONTROLLER.

then reduce the cost of production and enable every part of the mechanism to earn its share of the fixed charges. The reduced expenses, and the larger earnings in the extinguishment of the standing charges, will go far toward multiplying the profits of long hours' use, even at largely reduced rates. Moreover, it has been repeatedly demonstrated that such increased demand for long hours, and the resulting improvement in the load factor of the whole outfit, is of itself the means of a great saving in the actual cost of generation.

This matter is too well understood to require any discussion, but as a single example, it may be mentioned that at Brighton, England, it was found that an improvement of 3 per cent. in the load factor had the same effect in reducing the total cost of producing electricity as if the coal bill had been reduced 15 per cent., the charge for coal in this case being $5 per ton. The importance of accomplishing results of this nature has been very generally admitted. The difficulties encountered in the use of a double rate method have been such, however, as to seriously affect its adoption, although a large number of the leading central station managers regard it as the most complete and simple solution of the problem. The objections





FIGS. 4 AND 5.—THE OXLEY MULTIPLE RATE METER CONTROLLING SWITCH AS ARRANGED FOR TWO METERS AND FOR ONE METER.

urged against it seem to have been due to faults in the means by which the method has been practiced, and not to any defects inherent in the method itself.

Among the devices heretofore proposed the best was probably that employing two separate meters, or meter dials, one to register all the current used during the hours when a low rate was charged, and the other to register that used at a higher rate. This required the two meters to act alternately. Their operative alternation was effected by a clock at each point of consumption. The expense of installing such apparatus upon a system of even an average extent, would be large, and would materially increase the fixed charges.

But a more serious objection was found in the great liability of clock gearing to stop, or become wholly unreliable, when used to make and break an electric circuit. While this may be overcome to some extent, by using clock gearing of the best manufacture, the evil cannot be entirely eradicated, and the large increase in cost, due to the price of high grade clock movements, would not be compensated by the removal of the objections against the cheaper grades. The frequent inspections necessary, the numerous removals of clocks for repairs and regulation, and the winding and setting of a large number of such clocks, would evidently require an increase in the number of employés.

As one of the chief objects of a system of charging should be to enable the company to reduce the cost of generation, and lower the rates for current, a method that enlarges the running expenses, is, to that extent, hostile to the very purposes for which it is adopted.

It has been proposed to meter a double rate upon a single meter; the speed of the latter being varied by inserting a resistance in an auxiliary circuit at the central station. The plan was to connect all the meter shunts with a separate wire, run from the station to the points of consumption, and to vary the voltage on this wire, by the insertion of resistance at the central station to regulate the speed of the meters, so that they should register a part only of the current actually used during the hours when a low rate was given. One objection to this method is that the interruption of the auxiliary circuit would cause every meter to stop. A more serious objection however, is that the necessary drop of voltage upon the separate wire would be likely to seriously impair the accuracy of the results obtained.

A single meter, however, can be used in a manner that removes all objection, and gives accurate registration. By the use of the same form of controller, to be described later, a resistance can be inserted in each meter circuit, at the hour when the low rate is to begin, and maintained therein until the end of the low rate period. This resistance is graduated to retard the speed of the meter to a degree representing the ratio the low rate bears to the full rate. When inserted the meter will register only a part of the current that is used. By the insertion of this same resistance at each point of consumption, the provision of an auxiliary circuit is avoided, and no inaccuracy can be produced by a drop in the voltage. This plan has the advantage of economy, by saving the expense of a second meter at each point of consumption. In some instances this saving may be important, and it is of course desirable in all cases. The plan of using two meters, registering alternately, has the merit of simplicity, and is preferred by the average consumer, who can easily understand it and calculate the amount of his indebtedness. The single meters can be connected with the same ease and simplicity as the two separate meters.

The chief difficulty in the way of the double rate method—or, as it is sometimes termed, the differential rate, based upon the time of demand—seems to have been the absence of suitable mechanical appliances by which two meters could be duly controlled, one to meter current at a low rate, and the other at a full rate and in such a manner as to fully protect the company against fraud, secure accuracy, and avoid any material increase in the fixed charges, due to large outlay for apparatus. A description of the apparatus, and the method of

controlling it, as now installed upon the system of the company using it, is as follows:

At each point of consumption is placed a small electro-magnetic controlling switch, shown in the accompanying Figs. 1, 2 and 3. The parts are all enclosed in an aluminum case, 4½ inches in length and 3½ inches in width and depth. The enclosed parts consist of two independent electro-magnets, A and B in the diagram Fig. 4, and a pivoted arm G carrying an armature and knife contacts, and arranged between the electro-magnets. Upon each side of the pivoted arm are two clips, C and D, which clips are connected to the terminals of the windings of the electro-magnets A and B, the connection for each clip being made with the magnet lying on the other side of the pivoted arm. The second terminals of the windings of the magnets are connected (in a three-wire system) to the positive service wire P, and the neutral house wire N.

Two clips, E and F, one on each side of the pivoted arm G, form part of the armature circuits of the two meters M, M. These meters are shown in the diagram as being of the high efficiency type of Thomson wattmeter, and they are connected with the controller at each consumer's premises by a wire led from the middle right-hand binding post, connecting with the shunt or armature circuit, to the right-hand terminal at the top of the controller case. This is the only change made in the normal connections. In Thomson meters of other types, not having the extra binding-post, a small hard rubber block is attached to the wooden back piece, between the binding-posts. On this rubber a narrow strip of brass is mounted, having a small screw at each end, to connect with the terminal of the controller, and with one of the armature connections.

In meters having shunt circuits, such, for example, as the Edison chemical meters, as well as other types, the manner of connecting the controller is practically the same. In some forms of meters, however, as those provided with a series winding only, a modified construction of the controller is used, by which each meter is wholly disconnected, when its period of registration is terminated.

The pivoted arm G carries two knife contacts, one of which is connected to earth, and the other to the neutral house wire. The lower knife, having an earth connection, is struck into one or the other of the two clips, C or D, which connect with the terminals of the two electro-magnets. One of these controllers is placed at each point of consumption.

It will be seen from the diagram, Fig. 4, that by throwing the pivoted arm G to one side, the armature circuit of one meter is opened by the withdrawal of the upper knife, from one of the clips E or F, while the entrance of said knife in the clip on the other side of the pivoted arm completes the armature circuit of the other meter.

The whole system of meters is controlled from the central station, where a small double-throw switch is placed. Two of its clips, H and I, one on each side of the switch arm, have an earth connection. Clip K, on one side is connected to the positive, and the clip on the other side is connected to the neutral of the system. When the arm of the switch is closed or thrown into the clips on one side, the circuit will be from the positive, over the switch-arm and clip I to earth, then at each consumer's station, by the lower knife and the switch arm G, through the clip C, in which the lower knife is lying, thence through the winding of the magnet B, on the other side of the switch-arm G, and then to the neutral house wire and main. The switch arms at all points on the system are by these means thrown simultaneously into the clips, opposite those in which the knives were resting.

At the instant when the lower knife on the controller arm withdraws from the clip in which it rests the circuit of the electro-magnet that produces the movement of the arm is opened at the clip. As the same knife strikes into the corresponding clip on the other side of the controller arm G, it completes at that point the circuit of the magnet which will be energized when the switch at the central station is thrown into the two clips opposite those in which the switch was previously closed.

An indicator is arranged at the central station to show at any moment at which rate current is being metered. It consists of two dials, having suitable words inscribed, to denote the difference—"Day" on one and "Night" on the other dial answers the purpose. The two dials are illuminated by lamps placed behind them, and cut in alternately by the operation of the station switch.

Several things are noticeable in the arrangement described: First, the automatic breaking of the circuit of the electro-magnet, by which the throw of the pivoted arm of the controller is produced, and the completion of the circuit of the other electro-magnet, at the opposite clip, by the same movement of the arm. Every controller upon the system thus cuts itself out automatically, by the simple movement of the pivoted arm G.

Second, the marked simplicity of construction, and arrangement of parts, by which liability to become disordered and tendency to depreciation are reduced to the minimum.

Third, the extremely brief period that current remains on the control circuit, this interval being measured by the time required after one magnet is energized, to enable the knife to draw out of the clip which forms part of the circuit of that magnet.

Finally—and this feature is the most important of all—the control apparatus throughout the entire system is installed and operated electrically from a single point (the central station), without the trouble and expense of providing a wire, or wires, for the control circuit. This is a feature of no small advantage in any case, but where the mains are not laid in subways and where, as in the Edison system, the wires are piped and buried beneath heavy block pavements or asphaltum, the labor and cost of laying a control circuit would be very great.

Upon the lines of the company where the apparatus is installed the mains are in conduits in which two disused pressure wires were found, each No. 16, B. & S. gauge, and partly as a matter of convenience one of these wires was used for the circuit, controlling a number of the earlier installations. With others, two circuit wires were connected, the object being to ascertain if there were advantages in one arrangement, as compared with the other. Repeated trials and continuous use, extending over a period of nearly six months, have shown that the accuracy of control and certainty of operation were the same.

Dispensing, therefore, with wires for the control circuit, the cost of installation is reduced to a point so low that the addition to the fixed charges caused by the complete equipment of a system with the apparatus will be inconsiderable.

The controllers, which practically constitute the entire apparatus, are simple and inexpensive, and are connected and disconnected quickly and with ease. Each controller takes from one-fortieth to one-twentieth of an ampere for its complete operation. The small current and the high resistance of the electro-magnets, which are wound with No. 40 wire, and have 2,000 ohms resistance, or more, render an ordinary resistance, due to a poor ground connection, of no consequence.

The importance of improving the load factor, as the means of reducing the cost of generation, is well established. The necessity of effecting this is evident by the readiness with which many central stations have installed costly acccumulators, which have been thought by some to afford a solution of this problem.

Accumulators are valuable, no doubt. They come to the rescue in the event of a break-down; they steady the load; they can supply a sudden large demand for current which happens during peak hours, and in other respects they are useful adjuncts of a central station. Moreover, they improve the load factor of the generating mechanism, but not the load factor of the feeders and mains.

The latter, which may constitute by far the largest part of the investment in systems of ordinary extent, are not affected economically by the presence, or absence, of accumulators. There are, however, objections to them. They are highly expensive; they suffer a loss in efficiency of 25 per cent.; they depreciate rapidly; they occupy much space in the plant; their upkeep is costly, and they require a large outlay of capital with respect to the output.

On the other hand it has been shown repeatedly what is the advantage of increasing the hours of consumption, and thereby improving the load factor of the entire outfit. It is only by offering effective inducements, which bring about a material extension of the hours of consumption, largely increase the adoption of electric energy for every purpose for which it can be adopted, and enable it to compete with gas and steam, under conditions of practical equality, thus only that the "hills and hollows of the load curve" can be smoothed out, and the actual cost of production reduced to a point that will remove the incentive for maintaining private plants, and

the substitution of gas and incandescent burners in place of the electric light.

In an article by Prof. Marks, of recent publication, a tabulated statement was given, setting forth the results in a given case of increasing the hours of consumption. Among other points shown it was stated that an incandescent lamp of 16 c. p. burned two hours daily cost each year $2.16, and yielded an annual profit of $2.63. If the use be extended to 12 hours daily the yearly cost would be $7.26, and the yearly profit $21.46. Here the improvement of the load factor, due to an extension of the hours of use from two hours to six times that number, multiplied the annual cost by 3.36 and the yearly profit by 8.16.

It is well understood that the standing charges may constitute at least 85 per cent. of the total annual expenses of a generating plant. The remaining 15 per cent., therefore, represents the yearly running expenses, fuel being in most cases the largest single item. A central station, therefore, can double its output without adding to its expense account more than another 15 per cent.

Prof. Thomson, in speaking of the problems that confront central station managers, says that improving the load diagram is apparently of more real importance to them than systems that would double, or even treble the present coal efficiency; by which is meant the percentage of energy value of the fuel, converted into electric energy. It is well known, also, that the condition even arises where a given load, which will improve the load factor, without affecting the maximum load, would be profitable at a rate less than cost, the profit

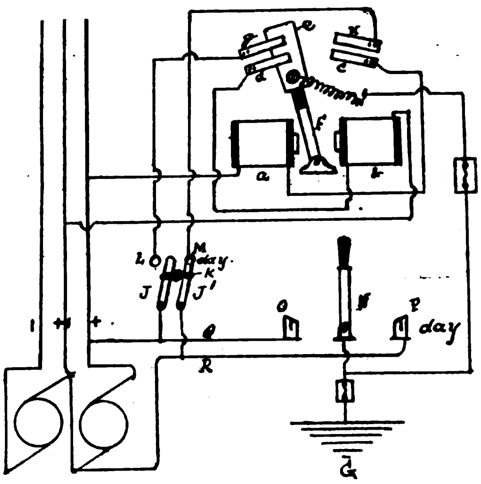


FIG. 6.

being made by the increased efficiency of the whole outfit.

Central station men cannot be misled as to the plain indication for the future. The multiplication of private plants, the increasing frequency with which incandescent gas burners are displacing electric lamps, and the readiness which many gas companies have shown in reducing their charges, all point to the conclusion that a reduction that will permit competition with gas and steam is the only condition upon which the general extension of the use of the electric current can be assured.

One result of the new method adopted has furnished in this connection a gratifying assurance of the benefits to be derived. A large mercantile house, in which lamps are burned all day, to light the basement, had substituted gas in place of the incandescent lamp. Since the introduction of the double-rate method, however, the gas lights have been removed and the electric lamps restored. Both changes were made in the interest of economy.

The duration of the hours of low rate will be fixed by the manager of the central station. The time at which this period begins will be regulated by the time at which the peak hours may be expected and this will be, in a measure, influenced by the season of the year. For instance, in winter the high rate, or full rate period, may begin at 4 o'clock p. m., and continue until, perhaps, 11 or 12 p. m. In summer, when the evenings are shorter, the hour at which the full rate begins and ends will be varied in accordance with the time when the maximum demand upon the generating plant may be expected.

The controlling switch at the central station is placed upon the switchboard at a convenient point. At the hour fixed for the change from one rate to the other the employé throws the switch blade on the switchboard into the clips which form part of the circuit of the electro-magnet that is to operate the pivoted arm of the controller. The switch blade need not remain in the clips more than one or two seconds and in that time every pivoted arm of every controller on the system is withdrawn from the clips in which it rests and thrown into the clips on the other side of the arm. This action, where two meters are used, opens the armature or shunt circuit of the meter by which one rate is registered, and closes the corresponding circuit of the other meter. Thus the former ceases to act at the moment when the latter begins.

If a single meter only is installed at such point of consumption as shown in Fig. 5, the action of the controller is the same, but instead of the alternation last described, the throw of the pivoted arm of the controller simply inserts, or cuts out, a resistance in each meter circuit which varies the registering action to the required degree. The same result can be produced by causing the pivoted arm of each controller to shift the meter circuit from the two outside mains of a balanced system to one outside and the neutral. This varies the voltage in such manner as to produce a registering action of double the speed in one case, as compared with the other.

As it is possible that a temporary ground may accidentally occur on one of the mains, by which the controllers may be operated at the wrong time, a separate controller is mounted on the switchboard and connected in the same manner as the others that are placed at the several points of consumption. Upon the occurrence of a ground this controller will be the first to operate and will attract the attention of the employé at the switchboard, who will, in such an event, operate the main switch and thus restore all the controllers to their proper position. Means, however, have been provided by which this result can be accomplished automatically, and although the apparatus is very simple, its description and illustration will be reserved for a future article.

While writing this article the author's attention has been directed to inquiries concerning several points which it was thought unnecessary to consider in the space at his command. These questions relate, in part, to that form of the system in which a ground circuit is used, and as economic construction will award this form the preference, as it entirely dispenses with a separate metallic control circuit, and thus avoids the expense of tearing up pavements to lay it, it seems essential to point out the only difficulty that has been suggested to the writer, and to describe briefly the very simple means by which this difficulty, which had been anticipated, is entirely removed.

Wherever the ground circuit is used, it is evident that an accidental ground at any point upon the system may operate every controller, and, by prematurely throwing the armature bar over toward the magnet energized by the circuit that is closed through such an accidental ground, the meter registration at every point will, from that moment, be at the wrong rate. Unless this disturbance is corrected without delay, the results may be serious. If the ground occurs during the low rate period the consumers are the sufferers—for a comparatively short period might be enough, where current is used for power, to largely affect the monthly bills. But the generating company, while an involuntary gainer in a monetary sense, may lose even heavily in the diminished confidence of the consumer, and is fortunate if it escapes strong suspicion of having employed dishonest methods.

To effectually guard against all objectionable results possible from such disturbances, by automatically restoring the controllers to the condition that corresponds to the rate the meters are registering, when the ground occurs, a very simple apparatus is placed at the central station, at any convenient point. It is shown in diagram in Fig. 6, and consists of electro-magnets A and B. The first terminal of the magnet A is connected to the positive side of the system and the second terminal carried to a clip C. The terminals of the magnet B are connected to the neutral and to a clip D, lying opposite the clip C. Between these clips is a single knife E, carried by an insulated bar supported by the armature F. Upon the same side with the clip D is a clip G, and opposite it is a similar clip H, so arranged that, when thrown by the electro-magnets, the knife will enter both clips on the side to which it is thrown.

At a convenient point is a switch consisting of two arms, J,

J^1, pivoted at one end, and connected by a pivoted, insulating bar K. Thus, when moved in unison, one arm may be placed on a contact L, and the other removed from a contact M, or vice versa. The small, single-pole, double-throw switch, the arm W being held by a spring out of its clips O and P, is the control switch used at the central station. Its clips are connected to the positive and neutral by wires Q and R respectively.

It will be noticed that the apparatus bears striking resem blance to the controllers. Its construction is varied but slightly, and there is no increased complication. The operation is as follows:

As shown in the diagram, the controllers have brought the day-rate into registration. This has been done by first moving the connected arms J, J^1, to the position shown, and then closing the arm N in the clip P. Upon releasing this arm it is thrown out of the clip, as shown, by a spring or other suitable means. The circuit completed by it has not only operated all the controllers on the system, but has also energized the magnet A and thrown the knife E into the clips G and D.

It will be seen that the controllers were last operated from the neutral side of the system, and therefore, should a ground occur upon either the positive or negative, the magnet B will be energized, drawing the knife E out of the clips in which it lies and into the opposite clips. As it enters these clips the positive is again grounded, and all the controllers are restored to their original position. As the ground is of short continuance, the knife E is automatically restored to the position shown in the diagram. As some of the controllers may be sluggish, it is well to retard the movements of this knife by a dash-pot, or other suitable means, to give time for the complete restoration of all.

An advantage is obtained by winding the controller switches for 200 volts. Not only do they then require less current for their operation, but they are controlled from the central station by grounding either the negative or positive side of the system. A ground on the neutral, therefore, as it results in 100 volts only, does not affect the controllers, such a pressure being insufficient for their action. Thus, disturbances due to accidental grounds upon the neutral, are excluded. Moreover, if a ground occurs on the side from which the controllers were last operated, no disturbance can result. The liability of such disturbance is thus greatly reduced. When they do occur, the results that follow will be instantly corrected, in the manner and by the means decribed.

Greater New York Celebration On New Year's Eve.

AMONGST the features of the celebration on New Year's Eve, at City Hall Park, to signalize the creation of the Greater New York, the electric lighting effects took a leading place. Stimulated by its successes on Election Night, as recorded already in these columns, the New York Morning Journal determined to go even further than at that time in the use of spectacular electrical effects; and it called once more upon J. B. Colt & Company for assistance in carrying out the ingenious and original ideas evolved by Mr. E. Z. Gerould, private secretary to Mr. Hearst, and business superintendent of the paper. It is needless to say that these plans were not evolved in a day or carried through without considerable work and skill.

The Morning Journal and the Morgen Journal occupy the northern half of the Tribune Building on City Hall Park, and their offices on this occasion were one blaze of lights. To begin with, there were two long strings of incandescent lamps, red, white and blue, from the cornice to the sidewalk, the upper ends being marked by large brilliant stars of lamps. Across the top of the building below the cornice stood out the full name of the Journal in lamps; and on the roof were ten Colt photo-engraving arc lamps in a row each with an attendant, and each using about 25 amperes. On the front of the building were seven "balcony" reflector lamps, arranged in two vertical rows of three each and one in the middle. Each of these lamps with a powerful reflector, burned three-quarter inch carbons and required 40 amperes; they as well as the lights on the roof being also provided with color screens. Over the entrance to the Journal office was placed a projection searchlight, with stencil slides, 5 inch condensers, with parallel beam, and using 40 amperes with one-inch carbons.

Across the Park on the City Hall itself were placed two more of these projection searchlights, one on the eastern end being used as a signal for all the others, in change of color screens, flashing in and out, etc. Below the lamps, on the front of the building were two American flags, of lamps, operated with motor and commutator in such a way as to make the flags ripple. Along with these were other set, emblematic pieces.

Directly south across the Park, from the City Hall is the General Post Office, and here fronting on the Park were mounted two more projection searchlights, one at each end, deriving current from the plant in the building. All these projection searchlights threw their beams and their stencil mottoes around in a lavish way, and when a big balloon was sent up by the Journal followed it with their beams until it had let down its flag and disappeared altogether in the dark vault of night.

There were many minor and harmonious effects. All the arc lights of the Brush Company in the Park had been fitted with red, white or blue globes, which shone brilliantly through the trees. A fantastically charming effect was created by long streamers of colored paper tape let loose by the Journal, in every direction, and sent spinning from roofs, from the sidewalk, and everywhere, until trees and buildings and people were all in a maze of these fine threads, which showed up beautifully under the vari-colored and changing beams of the electric lights. Added to all this, was the colossal firework display of the Journal. Its magnitude may be judged from the fact that no fewer than 5,000 thirty-six inch bombs were let off at the height of the jubilation.

Electric Freight Locomotive on the Hoboken, N. J., Shore Road.

THE use of electricity for switching purposes on the steam railroad, in place of the noisy drill steam engine, takes another step forward; this time on the Hoboken Shore Road, Hoboken, N. J. The full name of this road is the Hoboken Railroad Warehouse and Steamship Connecting Company. It runs from 17th street, Weehawken to 4th street, Hoboken, along the water front, or from the Erie tracks at Weehawken to the docks of the North German Lloyd Steamship Company, Hoboken, a distance of about two miles.

This road was opened for traffic on September 20, 1897. It was constructed to provide connecting facilities between the tracks of the railroad companies entering Hoboken and the numerous warehouses and docks which line the West side of the North River from Hoboken to Weehawken. It is double track over a private right of way from 17th to 14th street, single track down Hudson street to 11th street, and double track along the River Walk to 4th street, Hoboken.

The switching of the cars for the past three months has been effected by a repair car of the Hudson County Electric Railroad Company. The new locomotive was put into regular service on January 4, 1898, hauling trains of loaded and empty freight cars between the docks and the Erie track. The difference in its operation from that of the common drill engine is immediately noticeable. The electric locomotive responds instantaneously to the movement of the controller handle and starts without jerk or noise, tightening up the couplings uniformly or coupling the cars together so gently that no jar is perceptible.

The locomotive was constructed in the shops of the General Electric Company, at Schenectady, N. Y., and somewhat resembles in appearance the electric locomotive in use on the Manufacturers' Railroad, which connects with the N. Y., N. H. & H. R. R. tracks at New Haven, Conn., and the giant locomotives now handling the entire freight traffic of the Baltimore & Ohio Railroad, through the Belt Line Tunnel at Baltimore. It is mounted on two four-wheel trucks, each axle

carrying a G. E. 2,000 motor, giving the locomotive a total of 540 rated h. p. The weight on the drivers is 57,200 pounds; the drawbar pull is 10,000 pounds. The locomotive is driven through a single reduction gear of very low ratio. The speed is correspondingly low, and is rated at 8 miles an hour when hauling a heavy load.

At each end of the locomotive is an automatic coupler, and a small railed platform for the brakeman in charge of the trolley pole. The cab is of iron and resembles a double steam locomotive cab, with a sloping tender shield at each end. Drop windows are set around the four sides of the cab, affording an unobstructed view in all directions to the motorman. A sliding door on each side gives admission to the locomotive. The interior of the cab is lined with cherry and is a spacious and well lighted room. The fittings are all of polished brass or nickel. On each shield is a headlight; in addition one shield carries a bell, the other a chime whistle. Beneath one of the shields are four packed card resistances, two sand boxes, the compressed air tank and the equalizing air tank; beneath the other, eight resistances, two sand boxes and the motorman's tool box. At one end of the cab is placed a controller of the series parallel type known as the L-2. It contains, of course, the magnetic blow-out and is arranged to operate the motors either four in series or each two in series multiple. Beside the controller is the air brake handle and the two valves of the sanding arrangement by means of which the sand is blown by the compressed air under the wheels.

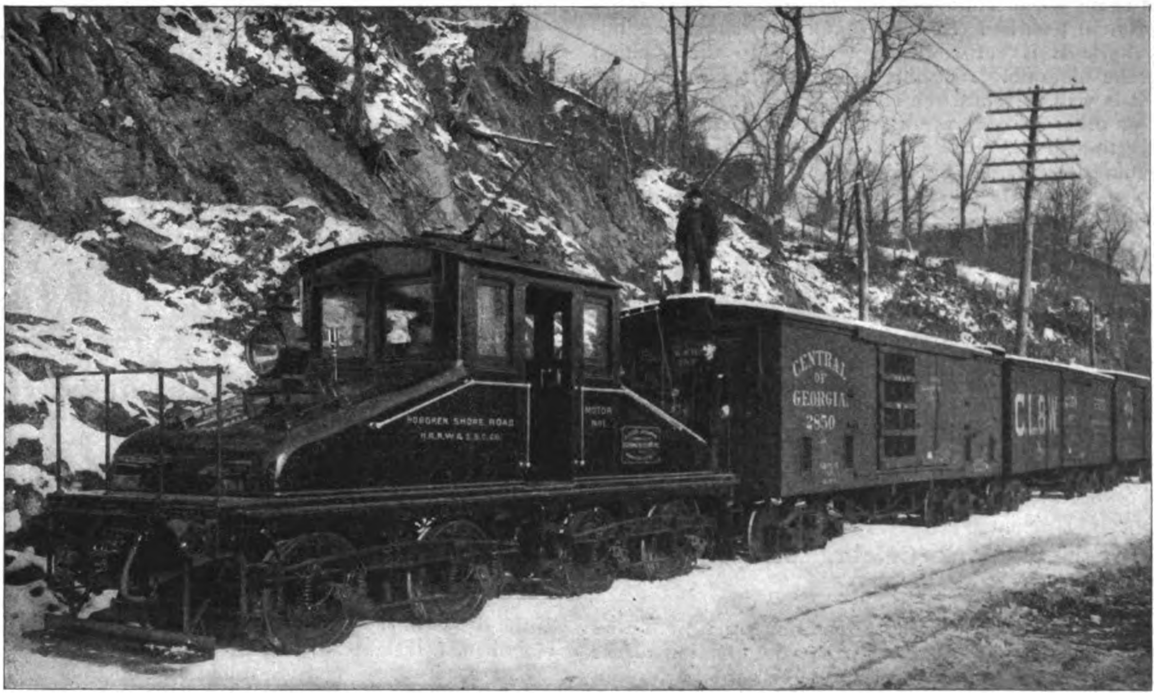
In front of the motorman is an air brake gauge, and above it an ammeter reading to 500 amperes. Fastened to the roof of the cab is an "L" automatic circuit breaker set at 500 amperes. On the other side of the controller, from the motorman, is an "M" circuit breaker and an automatic governor switch for the air pump, placed at the other end of the cab. This is a single cylinder pump driven by a 3 h. p. iron-clad bipolar slow speed motor. The operation of this air pump is automatic. When the air in the tanks is at normal pressure the governor switch is opened. Blowing the whistle, applying the brakes or using the sander causes the pressure to fall. This closes the switch automatically and starts the motor and pump. The cap is lighted by five standard Edison railway incandescent lamps.

The dimensions of the Hoboken locomotive are: Length over all, 29 feet; width, 8 feet; height over trolley stand, 13 feet; wheel base, 5 feet 6 inches; truck centers, 12 feet 9 inches; weight, 57,000 pounds.

The overhead wire is No. 00, suspended from wires strung between octagonal cedar poles, except at two or three points, where bracket construction is used. Where the locomotive turns in from Hudson street to the River Walk, a peculiar condition has caused a special method of bracket construction. It was necessary for the overhead line to be so set as not to infringe upon the limit of the next property. Thus at this point the overhead line is suspended from two bracket arms, one 6 feet and the other 18 feet long. The current for the road is taken from the station of the Hudson Electric Light Company.

The Hudson Shore Road is one of the sub-companies of the Hoboken Land and Improvement Company, organized fifty-two years ago, under a special charter, by the Stevens family to consolidate their interests in their several Hoboken properties. The present head of the Stevens family, Col. E. A. Stevens, is president, and Robert L. and Richard Stevens are respectively first and second vice-presidents; the general manager and treasurer is Palmer Campbell, and the secretary, W. A. Macey.

The trial trip of this locomotive was witnessed by representatives of all the railroads having offices or termini in New York and New Jersey. The locomotive was coupled to eight loaded freight cars with an aggregate dead weight of 295 tons. It handled this train with ease. It was then coupled to a number of passenger coaches and the party made the journey over the line from Hoboken to Weehawken and back.

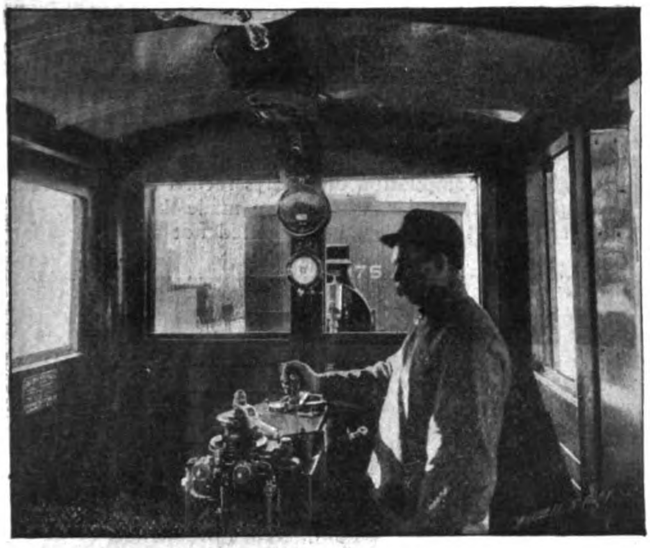


GENERAL ELECTRIC LOCOMOTIVE HAULING FREIGHT CARS ON SHORE ROAD ALONG THE HUDSON RIVER FRONT AT HOBOKEN, N. J.

At the luncheon which followed, two interesting speeches were made. Mr. F. Le Bau, general freight agent of the West Shore Railroad, pointed out emphatically the usefulness of such a road as the Hoboken Shore Road in facilitating the transport of merchandise directly from the steamships to any part of the country, and of the rapid switching electric locomotive, by means of which the freight cars could be handled more easily and more expeditiously than with the ordinary steam drill engine. Mr. W. J. Clark, general manager of the Railway Department of the General Electric Company, in an interesting talk full of reminiscences of the early days of the street railway struggle, said:

"Ten years ago, the development of three things made electric street railways practicable and profitable. These were the under-running trolley, the carbon brush, and the modern method of motor suspension. The development of three other things now renders the general application of electricity to standard railroads both possible and probable. These are the safe breaking of heavy currents, high voltage for their transmission and methods for their application to almost any load

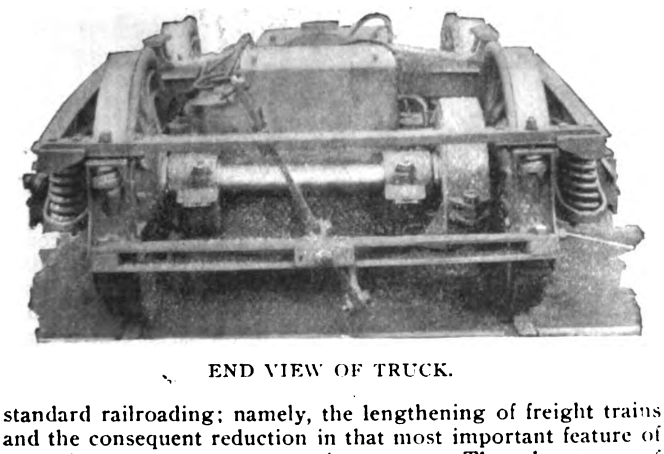
on any portion of a line. Other features are being developed that will seriously affect the result; not the least is the Sprague system of multiple unit control, increasing the flexibility of the already most elastic of all transportation agents, and while the economy of electricity has already been thoroughly demonstrated in performing the same service as by steam or animal traction, so far as passenger service at least is concerned, something beyond the mere question of economy has now to be



VIEW OF INTERIOR OF CAB.

considered; to wit, accomplishment by electrical methods of what would be entirely impossible with steam. The first steam railway man within my range of acquaintance to fully grasp this idea, is Mr. John Lundie, consulting engineer of the Illinois Central Railroad Company, who has set a pace on acceleration that would not have been dreamed of two years ago, and the schedule which he has mapped out for the contemplated electrical equipment of the suburban lines of his company involves a rate up to 40 miles per hour in 20 seconds. That this is practical has already been demonstrated. In fact so high a rate of acceleration has been made as 43½ miles per hour in 20 seconds, so that the practicability of Mr. Lundie's plans has been thoroughly demonstrated. This for passenger service.

"In another direction even greater changes may be prophesied which will come from the adoption of electricity in



END VIEW OF TRUCK.

standard railroading; namely, the lengthening of freight trains and the consequent reduction in that most important feature of operating expense, transportation wages. The advantages of electricity will have so thoroughly demonstrated themselves in the directions suggested that instead of main steam lines with electric feeders, in ten years it will be a question of electrically operated main lines with steam feeders through the sparsely settled districts, and a more extended system of suburban and interurban electric roads in densely populated districts also feeding the main lines.

"The electrical engineer has much to learn from the steam railroad man and must constantly rely upon him for suggestions as to the best methods of making practical applications of electricity. The American transportation man and the American electrical engineer should go on hand in hand, continuing to lead the world as they now do in all transportation problems. The American engineer has won conquests abroad as well as at home; not the least is the solution of the problem of electrical equipment for the Central London Underground Railway, the most important of this character that has yet been accomplished. The American engineering plans were selected on account of their merit in the face of the severest competition from every European electrical manufacturing company, and no greater tribute can be paid to American engineering methods than to state that eighty per cent. of all the railway apparatus used in Europe is designed in America, so that the American engineer stands to-day head and shoulders above those of any other country. With the encouragement of the co-operation of American railroad men he is bound to revolutionize the entire method of transportation within a comparatively short space of time, so that American railroad methods will then, as now, be in advance of those existing anywhere else on the face of the earth."

Trolley Competition in Connecticut.

The annual report of the Connecticut Railroad Commissioners shows that there are 385 miles of trolley road in the State, an increase of about 32 miles over last year. The 29 trolley roads have $9,770,440 of stock issued, of which only $3,106,940 has been issued for cash. Their bonded debt is $9,092,800, and floating debt $1,071,421. They carried last year about 43,000 fewer passengers than they did in 1896. They paid in dividends $265,625, as compared with $221,119 in 1896.

No additional steam road has been built. Owing largely to trolley competition the steam companies carried 2,192,959 fewer passengers than in 1896. Passenger earnings of the steam roads fell off $154,341, and freight earnings $258,003; there are 1,984 miles of steam track in the State. The Commissioners say that no more steam roads are likely to be built in Connecticut. They question the safety from fire of the proposed combined engine and car.

Third-Rail Earnings Nearly Double.

Steps have been taken for the extension of the third-rail electric system from New Britain to Bristol, a distance of about seven miles. The official statistics show that the system now brings in between Hartford and New Britain about $258 a day, as compared with about $135 a day by the old steam railroad service of the two cities.

Exports of American Electrical Machinery.

The following are the values of instruments and apparatus for scientific purposes, mainly electrical machinery, exported from this country in each of the last four years:

1897	$3,054,453
1896	2,522,217
1895	1,912,771
1894	1,534,277

The rapid increase will be at once observed, says the Journal of Commerce, that the exports in 1897 should have been twice as great as they were three years before is striking evidence of the vitality of this business. The distribution of the exports cannot be given for the latest year; for the other three years it was as follows:

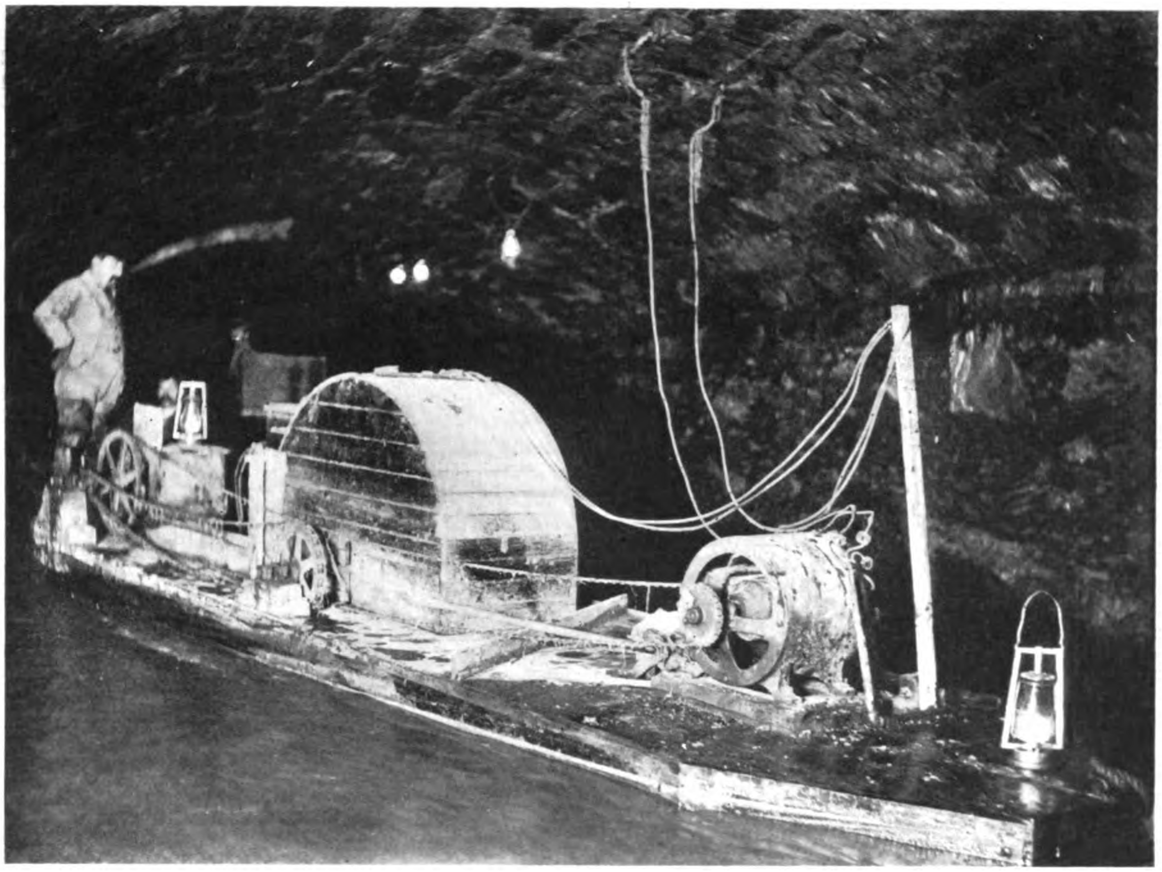
	1896.	1895.	1894.
United Kingdom	$385,575	$340,071	$380,016
Mexico	315,277	223,951	110,864
Brazil	282,798	165,551	100,857
Germany	201,360	135,333	101,515
Quebec, Ontario, etc.	159,375	209,443	170,885
France	158,733	157,625	79,329
Argentina	103,730	23,625	29,382
Japan	98,243	24,861	34,600
British Africa	94,541	17,651	3,359
Belgium	83,702	73,531	41,618
Cuba	54,238	94,149	143,501

METROPOLITAN TRACTION CO. says it is ready and willing to tackle the underground transit problem for the city. It has just made satisfactory terms of peace with its old enemy, the Third Avenue Railroad Company.

Electric Scows in Sewer Construction at Worcester, Mass.

IN the building of a sewer at Worcester, Mass., where electrically driven scows deliver the materials to the workmen, electric lights supply the necessary illumination, electric ventilating fans make work possible and electric pumps aid largely in rapid construction.

That city has a large sewer, eighteen feet wide and thirteen feet high, in which both storm water and sewage are carried away, but as it is desirable to separate the two in order to treat the sewage chemically, a smaller sewer six feet wide is being built inside the larger one, utilizing the bottom and one side of it for the walls. A cofferdam is constructed to enable the other wall to be built, and in order to deliver the materials to the workmen electric scows were rigged up, which work to perfection. About midway between the ends of the new sewer a small wharf has been constructed, and the materials are delivered to it by an incline through a hole made in the top of one wall. The incline and sewers are lighted by incandescent lamps, all the power being supplied by the Worcester Electric Light Company. The double trolley system is used, the wires being hung from insulated brackets in the arch in such a way that a trolley can be run on each.



ELECTRIC TOW BOAT IN MAIN SEWER, WORCESTER, MASS.

The improved towboat is a catamaran twenty-seven feet long and five feet wide, each of the small hulls being eighteen inches wide. In the middle of the deck is a small paddle wheel, boxed in to prevent splashing, and driven through the intermediary of sprocket wheels and a chain by an electric motor. At the stern are a rudder and controller of ordinary form, so that one man can manipulate both. There are six of these boats and they have readily handled 12,000 bricks, fifty barrels of cement and 100 barrels of sand daily. From these quantities it is evident that this original application of electricity is an important factor in the economical construction of this work. Besides lighting, ventilating the sewer, electricity is used to pump out the cofferdam. A special scow is used for this purpose. It is fitted with a motor, rheostat and centrifugal pump and takes the necessary current from the trolley wires. The whole plan has been devised out of second-hand machines and is very inexpensive, but capable, nevertheless, of saving many dollars.

The Saving Effected by Large Transformers

THE economic results obtained from the suppression of old type transformers by those of most recent and improved manufacture, and the substitution of one large transformer for several smaller ones, have been demonstrated very clearly and convincingly in a compilation of reports received from certain electric lighting companies, which have made the change. In almost every case the change has resulted not alone in a far more perfect operation of the system, perhaps a minor consideration, but in an actual, tangible saving in dollars and cents.

Improvement in transformer construction and the use of larger units follow naturally after similar developments already completed in the machinery of many of the large central stations of our country. The replacement of a large number of transformers of small capacity, manufactured when the art of transformer construction was not so well known as it is to-day, by a few improved transformers of large capacity has produced, and is producing, results startling in their importance. The figures shown in the compilation are interesting and should compel the attention of the manager of every station supplying current through transformers.

The first instance is that of a company operating in a town of 56,000 population in Massachusetts. In this case 57 small transformers built in previous years were supplanted by 18 of one of the latest types. The total light capacity of the superseded apparatus was 1,499 lights; of the newly installed transformers 1,624. The total core loss of the old transformers was 5,866 watts; of the new, only 1,348. So much for the electrical facts.

The saving in dollars and cents is calculated as follows: 39,578 kilowatt hours are saved yearly by the change. The value of the saved energy may be estimated at $527.70, equivalent to a saving per light capacity per year of 36.2 cents. Neglecting all the advantages of the change, except those accruing from the decreased core loss, the expense will be met in one year and nine months.

The light capacity of the plant is increased 9 per cent., the core loss decreased 77.5 per cent. Furthermore, on account of the decreased core loss, not less than 4,518 watts are available for sale at the regular rate with the present station apparatus. This enables the company to add 90 lamps to its circuits, producing an additional income of about $675.00.

The second instance is in another Massachusetts town. Here 40 new type transformers supplanted 53 old ones. The total light capacity of those taken out was 1,135 lights, of the new 1,070. The core loss in the old type transformers was 4,845 watts; of the new type 1,343 watts. In this case the annual saving is 30,678 kilowatt hours, or about $409, and corresponds to a saving per light per year of 35.2 cents. The expense of the change, counting core loss alone, will be covered in two years and nine months. Three thousand five hundred and two additional watts are available for sale, increasing the income by $525 per year, while by the use of lamps of a higher economy, some 535 kilowatt hours additional are also available for sale.

There are still three more striking cases in Massachusetts of benefits derived from a similar change. In the first the regulation of the station had been so poor that the lamp bills had increased to such an extent that the question demanded immediate attention. While the saving was comparatively small, the beneficial results brought about by the change have proved highly satisfactory. In the second, 81 small transformers of old type were replaced by 3 of a new type. The core loss of the returned transformers amounted to 2,568 watts, of the new ones 280 watts. The resultant saving per annum is 20,043 kilowatt hours, or $267, the saving per light capacity per year 25.74 cents. This is an all day station and it is calculated that only eight and a half months will be required to wipe out the investment. The third case involves the supercession of 193 old type transformers by 37 new ones, the total light capacity of the former being 6,035 lights, and of the latter 8,210 lights. The total annual saving is 51,203 kilowatt hours, or $683, and the total saving per light capacity 14.68 cents. In five years and two months the cost of the change will be fully covered. The capacity of the plant has been increased 36 per cent., the energy required to operate it decreased 47.1 per cent.; 5,845 additional watts were made available, and thus an additional capacity of about 116 lights was obtained without adding to the station apparatus. If these lights were burned but three hours daily the result would be an additional annual income of $960. On account of the improved regulation entailed by the change, high efficiency lamps can be used and about 410 more watts saved. This adds $109.46 to the total annual saving.

Several interesting changes have also been made in the West. One instance in particular merits attention. The details of the change are not available, but by centralizing the transformer distribution, the rate of switchboard income was changed from 4 cents to 12 cents per kilowatt. Another Western plant reports that its 1,140-volt circuit equipped with old style transformers, showed 6 to 7 amperes in the day time, while with the new transformers only a fraction of an ampere is shown.

Facts such as these tend to prove not only that constant improvement is taking place in electrical apparatus, but that station managers are realizing that, to secure the most economical results on their systems, such improved apparatus must replace older types built when electrical knowledge had not reached its present high standard. A saving here, less trouble there, the extinction of a difficulty at another point, result in a general benefit which can be exactly calculated in dollars and cents, and thus tends to the general wellbeing of the progressive station and communities in which the newer methods are adopted.

LONDON POLICEMEN will, if a plan proposed is carried out, be equipped with portable electric batteries and lights on their helmets, as guides for the public during the delightful fogs which render London preferable to the Riviera in winter.

Niagara Falls Power in Canada.—A Menace to the Great Niagara Plant Overcome.

IN an address delivered before the Canadian Power League at Niagara Falls, Ont., last month, Mr. William B. Rankine, secretary of the Canadian Niagara Power Company, referred to the delays which had been experienced in carrying out the work on the Canadian side. These were largely due, said Mr. Rankine, to the fact that the entire undertaking on the American side involved so much that was experimental that the Canadian company did not feel warranted in going in for work on their side of the river until the American project had been gotten well under way. Besides the mechanical and electrical problems, there were others, and one of a most serious nature, was dwelt on at some length by Mr. Rankine. "We had supposed," said Mr. Rankine, "five years would have been plenty of time, but we had not been able to get our operating and transmission experiences fully, and now we had this other surprise. I did not tell that to the meetings held throughout the Province at that time; I could not as a business matter disclose that, but the fact was that early in 1897, three months before the time when we were expected to begin our work on the Canadian side, we discovered that the walls of our wheel-pit were beginning to come together. We had built a long slot there and we placed in that slot three of the wheels that were to develop 15,000 horse power, and we were going on extending that slot, putting in additional wheels in a row, as the engineers advised, and the same construction which had been adopted in the plans for the Canadian side. All at once in that slot, extending down practically all the 400 feet, the walls began to creep, threatening our plant, and I assure you it was a very creepy time for us. I told Mr. Premier Hardy that we could not make this public, but that he was entitled to know what was going on there, and until we knew where this surprise was going to land us, we could not build a similar slot on the Canadian side in that location. Of course we might find better rock, but we might find worse rock, but we wanted to know the condition to be encountered, the character of the rock, and the effect caused by the cutting of a slot that length and depth. We did not see how we could go on without an extension in the interests of the Canadian Company. That creeping of the rock stopped on the 15th of August, and the only reason I dare to speak of it now is that it has never crept since and we have completely stopped it."

In reply to some statements which had been made that the new electrolytic process industries at Niagara found their chief market abroad, Mr. Rankine said: "I took the trouble to ask each one of the companies on our side and ascertain about their foreign trade. We have six of these companies now taking from us about 7,000 h. p., for use in electrolytic purposes. The Aluminum Company told me they had used last year about one-third of their power to take care of the foreign market which now has fallen off rapidly because of a new manufactory started in Switzerland, and they said there would be no opportunity to use it on the Canadian side except for Canadian trade. I have tried to get them to come over here and establish a 1,000 h. p. plant but have not succeeded as yet. The Carborundum Company told me that their patents for furnishing carborundum for foreign use were owned abroad, and they therefore would manufacture in the United States for the demand in the United States and manufacture in Canada for the demand there. The Electro-Chemical Company, who make sodium, ship nothing whatever abroad. The Oldbury Electro-Chemical Works ship nothing abroad. The Carbide Works manufacture under the Willson patents, and cannot manufacture in Canada. Mr. Willson, a Canadian, controls the cabide patents in Canada and manufactures at Merritton. Now, just one of these six ships abroad one-third of its products and could perhaps manufacture that third in Canada, but will not. It is surely to our interests to encourage manufacturing where we can produce the power cheapest because we can there make the most money. If that is in Canada, why should we not encourage it here?"

Mr. Rankine also stated that arrangements had been made with the Park Railroad Company to deliver 300 to 500 h. p. for local power distribution at once; 1,000 h. p. in addition could be delivered inside of four months, and that could be increased to 5,000 h. p. if necessary. It was not intended, however, that this was to take the place of the proposed larger development.

Vol. XXV. NEW YORK, JANUARY 13, 1898. No. 506.

The Commercial Status of Telephony.

THE evils of monopoly have so often been dwelt upon in America that it may be fairly assumed every man is familiar with them, as well as with the advantages. The art of telephony has long been supposed to illustrate both sides of the subject, for while on one side the American Bell Company has been painted with all the lurid attributes of the devil, on the other side the public has been informed that the telephone is a "natural monopoly," whatever that may mean; and that the exclusion of everybody else from the field is due to the steady and legitimate absorption of every valuable patent or useful device bearing on the subject. The public as it reads these arguments and statements, pro and con, is free to choose in accordance with its previous condition of mind or purse, for there are some who took up telephone investments when they were a desperate chance just as there are others who would find fault with telephone service no matter who gave it or what price they paid for it.

Meanwhile the whole discussion is slowly but surely shifting to a fresh base, and a more rational, permanent point of view. Patent protection, however prolonged or reinforced, cannot last forever; the stars in the courses fight against it as well as every human passion that delights to aim at the shining mark of prosperity. When all has been said, and all has been done, one gets down to the platform of sheer business ability in conducting a great enterprise and its consequent success in meeting competition or giving public satisfaction. It is right that new ideas and their developers should be protected by patents and rewarded with royalties. It is inevitable that after a time the industry thus created should depend not upon heaven sent inventors, but upon the energy, skill and genius of another class of men, managers and engineers, of not less importance. Telephony to-day has certainly reached this second stage, and is at a point of the utmost interest in its development.

Let us take a concrete example and the nearest—New York City. Here we have a company which, to all appearance, is acting as though it had never heard the blessed word "patent," and as though it might soon be facing the fiercest competition. It is banking entirely, if we may judge from the indications, on the service it can give, and not on presumed ability to exclude a rival from the field. Things were not always thus, and the changes in policy are such as to inspire us to say that the happiest event in the company's history was the expiration of the earlier Bell patents, because it was at once thrown on its real, intrinsic, persistent and permanent qualities of merit. The first and great evidence of a change has been the radical, revolutionary change from a flat rate to a message rate, and thereby hangs the whole tale. It is a curious, striking parallel with the early days of electric lighting, when every light was furnished at a flat rate, and the meter was either unknown or anathema. To-day the electric light industry rests its case on metered current. To-day the telephone companies of the old school are ensuring their future by an analogous metered service of so much per message.

The results last year in New York City proper in the telephone field were in themselves ample vindication of this departure, and of the scientific, equitable system of charge, which cures many evils and eliminates many causes of complaint. It is doubtful whether any electrical industry in New York City, except the local Edison Company, shows such gains. At the end of the year there were in New York City 21,535 subscribers, and in allied Westchester County or Division, 1,880, making the remarkable total of 23,415 subscribers. The gain for the year was 393 in Westchester and 4,749 in New York, or a total increase of 5,142. Surely the change must justify itself to the management by such extraordinary gains. Another significant feature, bringing us back to our text, is the fact that of these no fewer than 17,447 were subscribers on a message rate basis, or 76.2 per cent., while the flat rate subscribers were only 23.8 per cent. Nor is this all, for the flat rate subscribers were steadily getting off the old basis all the year through, 485 changing in 1897, so that at the end of the year only 3,730 were left; and the revolution still goes on. It would be very interesting to learn how the situation is in other cities and whether they can compare with New York in this respect. We doubt it.

And this brings up the question agitated very vigorously by one of the city newspapers last week, which, quite oblivious of this notable change to a metered basis, began to talk about New York, Paris, London, Berlin, etc., as though the old basis still governed and as though a surface comparison could be fairly made, anyhow. Outside altogether of differences in rents, salaries, cost of materials, etc., all making for higher rates in this country, there are other things not mentioned. In Paris, for example, until quite recently, when you wanted a man, it has been necessary to give central his full name and address! That little fact alone is indicative of the modernity and efficiency of the service. How would a New York business man like it? In Berlin, the Government is now proposing a new scale of charges with all kinds of discrimination, the very contrary of the New York ideal of getting just as near a common, universal charge for the exact service rendered. Yet Europe is constantly held up as an example, whereas in every line of electrical service it is from ten to fifty years behind the United States, and does little else but adopt our inventions or copy our practice. If a service is in the hands of the Government, the price asked for it is utterly without value as a criterion of its cost. If the service is in the hands of a private company, it usually comes nearest perfection when carried along according to American methods and ideals.

Two-Rate Metering.

THE success of an electricity supply company depends upon its ability to deal with the public, for though its mechanical and electrical equipment may be of the best, its staff the most skilled, and its local resources abundant, there still remains the hard fact that the public is the judge and dictates success or failure. The income of a company, upon which depends its life, comes from a neighboring public whose opinion is paramount and final.

When electric current distributing companies were first started, little attention was paid to the effect of "fixed charges" upon the cost of the current since rates were high, the commodity new, and only indulged in as a luxury. In those days it was supposed that the cost of electrical energy depended upon the quantity generated at any one time and—since consumption was instantaneous—the quantity sold at any one time. Thus, favorable terms were made to consumers in direct proportion to their maximum demands. As central station plants became better organized and their business more extended, associations were formed for mutual benefit, and it was soon seen that companies having the same maximum output did not show the same unit cost for energy even when the prices of coal, labor and the different items making up the cost were at the same rate. This led to a careful comparison of local conditions and among other things the generating

and selling curve. It was then found that those plants having the highest percentage of average to maximum output were able to show the lowest cost per unit. Then, as will be remembered, came the introduction of the electric motor in an endeavor to increase this percentage output. In the meantime, to make the income more nearly correspond with the cost of generation, the flat or contract rate system was abandoned and the meter substituted.

While the meter had the desired effect of placing the business on a better financial basis it did little to improve the percentage of average to maximum load. In fact, in the majority of instances the meter system diminished the use of the current during the minimum, rather than the maximum, period, thus at once lowering the percentage and increasing the unit cost. In order to introduce the electric motor, selling prices for this device only were lowered during the motor period (which unfortunately often came during the maximum period), and thus, in the opinion of many companies, a paradox was presented; for it was always supposed that the unit cost of energy varied directly as the quantity, and yet it was found that by lowering the selling price during the seemingly high cost period, the average cost per unit was reduced.

As prices to the public were lowered, as the commodity developed from a luxury into a necessity, there came about a careful analysis of the cost per unit and the surprising effect of "fixed charges" became prominent. It was seen, in effect, that as the generation and supply were coincident the element of time was all important; but while for many years this fact was recognized, no definite application was proposed while dealing with the problem from a purely current supply situation leaving the option of use to the customer.

Mr. W. S. Barstow's "load factor system," explained by him elsewhere in this issue, is, we believe, a simple and effectual solution of the situation, reducing the supply of electrical energy to a percentage-on-manufacturing basis, which is the recognized foundation stone of all industries. Mr. Barstow's article clearly sets forth the reasons for the use of a two, or more, rate system.

A device for carring such a system into practical effect is also described in this issue, that of Mr. Oxley, showing how simply the system can be carried out in practice.

There is to-day no question which touches the central station manager closer than the question of rates. With the light thrown on the subject by Mr. Barstow we feel certain that it will be only a question of time when such a variable rate system will be in universal use, for the reason that it is a fair system—fair to the consumer and fair to the current supply company. Its introduction will be hastened when it is realized that such a system is a great load evener, and what that means needs not to be pointed out at this late day.

Electricity on the New York Elevated Railways.

AT last, it seems that the electrical conversion of the New York elevated railroad system is within measurable distance. We judge so, at least, from the authorized public utterances of Mr. George Gould who, in an interview, states flatly that the introduction of electricity on these roads has been decided upon and that the work will be carried out with the least possible delay. This action of the Company was somewhat foreshadowed by Mayor Van Wyck's annual message, and it is probable that the announcement of Mr. Gould, coming so quickly after the mayor's message, is not a mere coincidence. Whether this be so or not, the fact that the proposed tunnel railway scheme has for the present received a decided set-back makes it more desirable than ever that the elevated railways should be brought up to the highest possible state of efficiency and convenience to the public. That this can be done by electric traction no one will now care to deny in the light of the experience gathered in Chicago and Liverpool in elevated railway work. Of course, no other plan but the third rail is thought of so far as the system of current conductors is concerned, but as to the other details no facts have as yet been forthcoming. We fancy it will be a battle royal between systems of electrical control, such, for example, as between the locomotive car and the multiple unit individual motor car system. Then again, as to methods of current distribution; whether a number of power plants will be located along the lines, or a big central power plant installed generating high tension alternating current to be converted locally by rotary transformers. And who knows but that the alternating car motor may enter the lists as a competitor? Of one thing we feel certain, however, namely, that no matter what system is adopted, it will be an improvement over steam. New York has suffered long and patiently, and its deliverance from a continuous shower of dust and oil and from steam and noxious gases comes none too soon. Indeed, probably no other city on the face of the earth would have exhibited the equanimity and good nature which New York has shown for the past twenty years. It is to be hoped that the change over will be proceeded with without delay and thus add another factor to the improvements now so rapidly manifesting themselves in the metropolis of the Western Hemisphere.

While the above was being put in type, a rumor gained circulation in New York that at last a genuine contract had been awarded by the procrastinating Elevated management, and that the Walker Company has the contract to equip, as a start, the Second avenue line. This is not confirmed; neither is it denied, and one of the city papers has gone so far as to reproduce from our columns the drawings and data of Prof. S. H. Short, on the equipment of the New York Elevated, printed last August. We hope this is true, and shall be glad to see any such contract awarded, as it will mark the beginning of a now inevitable transformation. It is said that in return for the change to electricty, the Manhattan Company will secure the right to build spurs and extensions. Mr. George Gould is quoted as saying, that the adoption of electricity would result in a saving of at least 2½ per cent. The roads to-day are running 3,500 trains daily with 330 steam locomotives.

Politics in Detroit Lighting.

DETROIT continues to furnish a good deal of interesting matter in connection with the operation of its municipal plant; and now we have a very interesting article on the subject from Mr. George E. Fisher, a local electrical engineer of more than local reputation. He falls foul of Mr. Fitzgerald and one or two other men in great style and makes a number of striking statements. We think that anyone reading carefully Mr. Fitzgerald's article and this reply by Mr. Fisher will come to the conclusion that "politics" had vastly more to do with the putting in of the Detroit Municipal Plant than any real question of economy. The politics were also evidently pretty hot and so continue.

Mr. Fisher's comments on the results with the plant seem to us open to one comment, from ourselves, namely, that his figure of cost is not correct. It has already been pointed out in these pages that the alleged cost of $89.42 took no account of any insurance, or of depreciation, except on the single item of boilers; and that assuming 5 per cent. as fair, the actual cost per lamp was at once brought up to $102.49. Central station managers would be glad to meet their depreciations at 5 per cent. In commenting on our figures, president Hudson, of the Detroit Lighting Commission, said: "My own figure for an arc lamp has always been $100." We venture to point this out to Mr. Fisher, and to repeat our previous comment that the figure of $89.42, like the old Barrett figures in Chicago, might as well be dismissed right off from consideration, as not representing the actual facts. We would also like to call his attention to the official report just filed by Mr. F. L. Barnett, superintendent of city lights of Des Moines, Ia., in which he says that the item of $89.42 is expected to be at least $94 in the third year and adds: "I was advised that Mr. Dow, the first superintendent of the Detroit city plant, lost his position for having estimated that in ten years the cost per lamp in Detroit would not be far from $120." Nor is this all. Mr. Barnett has just visited Buffalo, and points out that there the price from the local company is only $109 for 2,300 lamps, and is to be $100 when 2,500 lamps are required. "The lighting service of this city is by far the best of any city visited; in fact, it is the best lighted city I have ever seen." We beg to extend our congratulations to Mr. Huntley upon this handsome compliment paid his work in Buffalo as a central station manager.

TELEPHONY AND TELEGRAPHY

Cable Coding and Cable Addresses.

THE increase in the number of Atlantic submarine cables, and the rapidly growing use of them in international affairs, have been responsible for a great development in the art of "cable coding" and "cable packing," or getting one word to express the exact meaning of forty or fifty, so as to reduce the amount paid for messages sent under the ocean. Some of the achievements in this line are very remarkable. although the fullness of many of the dispatches sent without cipher or code is not less striking. The lower rates for cable messages have not only increased the volume of business, but have made it absolutely necessary for every concern or individual with any kind of connections between this and the other side of the Atlantic to have a cable address. But this is not all. Where one is cabling frequently, the registered cable address of the correspondent is easily remembered; but there are occasions not a few when it is required to reach parties in a hurry whose cable address is not known; and the absence of a directory of this character has often been keenly felt. In fact, the want became so obvious that last year Mr. Chas. P. Bruch, a well known telegrapher, and now assistant secretary of the Postal Telegraph Company, undertook in association with Mr. C. W. Parker to get up a cable address directory. He soon found that the idea was appreciated, and as the work developed other well known officials of the Commercial Cable and Postal Telegraph Companies came to his aid. Last October, the scheme had taken on such importance and magnitude, that the Commercial Cable Company itself, realizing the value of the enterprise and desiring to have it as fully rounded out as possible in the accomplishment, took the significant step of guaranteeing the issue of 100,000 copies of the Atlantic Cable Directory and Code, thus gathered together; and also guaranteed the circulation of the books abroad.

The labor upon which Mr. Bruch has thus found himself engaged is nothing short of monumental. The book will reflect great credit on its compilers when it appears, and it would have been out some weeks ago, but for the intense desire of its authors to make it perfect and but for the inevitable tendency that such works as dictionaries, directories and encyclopædias have to grow in bulk and scope as they roll along. We have lately been afforded an opportunity to go over some of the printed sheets and later proofs with Mr. Bruch at his office in the Postal Building, and must confess our satisfaction at what has been done. The book itself, with a page face 10½ by 7 inches, was laid out for 600 pages; just how many beyond that it will run we would not like to pay for. The mere preparation and publication of 100,000 copies of such a book involves tremendous work, quite apart from cost; but that is only one side of the undertaking, and there are others of equal interest. To meet the outlay, the insertion of names has been by subscription, the name, business, business address, cable address and one classification being inserted for $12.50; while an additional classification is given for $2.50 extra. In return for this, each subscriber gets one copy free, and can have extra copies at $1.50 each, with discounts on quantities; making the book very cheap. The Atlantic Cable Directory and Code Company hopes also to meet its heavy expenses in some degree by the insertion of advertisements, such a book, lying always on 100,000 desks of buyers and sellers, having a distinct value in that direction.

These cable addresses now numbering roundly about 5,000 are arranged alphabetically by States, cities and names; supplemented by a classified business directory; and the collection is a marvellously complete and intersting one, because it presents in a way we have never seen before the business people of this country and Canada who have foreign relations for commerce, finance, etc. The growing nature of our banking business, the long arms our makers of machinery are reaching out, the growing field for our iron and steel, the big market for all our agricultural products—these and other features are all impressively brought to notice in the endlessly long lists of names that Mr. Bruch has for months been arranging with a lavish consumption of time and with an enthusiasm of no ordinary degree.

That, however, is but one-half of the story. The directory contains a cable and telegraph code of at least 50,000 words, selected from the official vocabulary authorized by the International Telegraph Bureau at Berne, and conforming strictly with the instructions of the Buda Pest International Telegraph Convention of 1896. But within that liberal range of 50,000 words, there are, as every experienced cable operator or telegraphic expert knows, many chances for hit or miss, many openings for bull and blunder; and Mr. Bruch has not only gone over every one himself, but a second specialist has been detailed to check up everything, with the sole object of rendering a cable message in code possible of one interpretation, and of one only. Here, too, is where the "packing" comes in, and every cable sender has been invited to contribute to the general fund the little wrinkles and phrases and cues that he has found best in his own line of work. The mine of experience thus opened up and the innumerable hints and suggestions thus poured into the hands of the company for digestion and assimilation, are simply surprising. Licking all this material into shape—some of it very unexpected—takes time, skill and patience; but when the Code comes out it will be all the better for the unavoidable delay that has in reality added to its intrinsic worth and utility. Every word in the Code will not only have the authority of the Berne and Buda Pest Conventions and agreements behind it, and therefore be acceptable at every cable office in the world, but it will have been sized up for the best service it can render in cutting down the number of words for which a cabler has to pay. Another excellent feature we note in the pages of the "Directory Code" is its shrewd and generous reserve of words to which those who use it can attach their own meanings and phrases. Every page carries this surplus, so that the owner of the book has a ready made code and a code he can make for himself, all in one.

The cable addresses are an interesting study, but we have room for only one or two of them, in our own field. The Western Electric Company has "Microphone"; the General Electric Company, "Genetric"; the Crocker-Wheeler Electric Company, "Crockwheel"; Shaw Crane Electric Company, "Cognition"; C & C Electric Company, "Electmotor"; H. B. Coho & Company, "Cohocomp"; Dodge Manufacturing Company, "Dodmanco"; Dyer & Driscoll, "Vernerve"; Eaton & Lewis, "Nerdis"; Herzog Teleseme Company, "Teleseme"; Johns Manufacturing Company, "Wardjohns"; McIntosh, Seymour & Company, "Toshmour"; The Okonite Company, "Okonite"; Spencer, Trask & Company, "Trask"; Westinghouse Electric and Manufacturing Company, "Converter." These are suggestive, some of them clever, and the whole list—if we may venture a mild pun—a very witches' Bruch of nomenclature.

The officers of the Atlantic Cable Directory and Code Company are: President, Geo. Clapperton, traffic superintendent of the Commercial Cable Company; vice-president, T. L. Cuyler, Jr., assistant treasurer, Postal Telegraph Cable Company; secretary and treasurer, Chas. P. Bruch, assistant secretary Postal Company; and general superintendent, C. W. Parker. These are directors, with Albert Beck, C. E. Merritt and W. K. Smith, all three well known officials in the Commercial Cable Company.

The Rutherford Secret Sounder.

THE introduction of typewriting machines in telegraph offices on which operators take down the messages as received has necessitated increasing the volume of sound emanating from the sounders in order to make their clicks clearly distinguishable above the click of the typewriting machine. The result has been that the noise in telegraph offices has in many cases increased to such an extent as to be a serious menace to the health of operators. Besides this, greatly increased all-round noise to large extent vitiates the effect of the sounder resonators.

It was with a view to reducing this noise and to make the received message entirely secret, if desired, that Mr. G. A. Rutherford has designed what has been called a secret sounder, which is illustrated in the accompanying engravings.

The sounder which is enclosed in a hard rubber case, is very light, the whole thing with conducting cord complete, weighing but four ounces. It can be used not only without

the slightest inconvenience to the operator, but much to his comfort and advantage; relieving him of all unnecessary nerve and physical strain. It can be attached directly to the main line where it acts as a combined relay and sounder, giving all the services of both, without any of the disadvantages and annoyances of a main line sounder.

The mechanism of this little instrument is very simple, consisting, as shown in Fig. 1, of a set of electro-magnets of from 2 to 150 ohms resistance (according to requirements). An

FIG. 1.—THE RUTHERFORD SECRET SOUNDER.

ingenious arrangement of the armature and lever, brings the former in actual contact with the poles of the magnets in such a manner as to double the working force of the magnets, and insures a much more prompt action of the armature than has been heretofore obtained. The armature lever is provided with hammers, which, in action strike upon a resonating plate; a shifter or switch at the side of the case draws the hammers from the plate and reduces the sound to a minimum. The adjustment of the retractile spring is absolutely direct, and is made from the outside of the case, although it is rarely ever necessary to touch it.

The engraving gives a view of the interior construction of the sounder with the cap or cover removed, and shown on the right. The cap is threaded, and is tightly screwed in place when the sounder is in use. There is never any necessity of removing the cap. The shell, enclosing the sounder, and the head band are made of hard rubber, and the parts of the instrument of aluminum and brass.

Owing to the loudness of the sound when the hammers

FIG. 2.—THE RUTHERFORD SECRET SOUNDER AS APPLIED TO OPERATOR.

strike upon the resonating plate, messages may be received with the sounder placed on the table or desk, and in this way it may also be used for a call; thus combining in one instrument both a loud and secret sounder, something which we believe has never been accomplished before. Should it be desired to take a secret message, the sounder is adjusted from the outside by means of the shifter above referred to, which is graded so that the operator may regulate the volume of sound to suit his own ear. This may be from the faintest click to the full volume of the loudest sounder. The instrument is then worn on the head, as shown in the engraving, Fig. 2, and messages may thus be taken known only to the sender and the receiver. The instrument being worn next the ear may be adjusted to its lowest capacity and still be distinctly heard by the operator, a great boon to one suffering from deafness. The case and head band being made of hard rubber, insures the operator from shock from abnormal currents passing over the line.

This instrument, as stated above, is especially adapted for use in offices where the typewriter is used in connection with telegraphy. For the secret service of the Government, for line inspectors, and for testing purposes the Rutherford secret sounder is also especially adapted, and it will no doubt find an extensive use in stock exchanges, brokers' offices, newspaper offices, etc. For local use these sounders are made with from two to twenty ohms resistance; for main line use the magnets are wound to a resistance of 150 ohms or higher. The sounder is manufactured by the Secret Sounder Company, of 115 Broadway, New York City.

Bell Telephone Instrument Output.

The American Bell Telephone Co.'s monthly statement of the output of instruments for December is as follows:

Gross output	26,374	Inc.	12,634
Returned	8,799	Dec.	1,102
Net output	17,575	Inc.	13,736
For the year ended December 20:			
Gross output	241,271	Inc.	49,185
Net output	148,404	Inc.	51,091
Total outstanding December 20	920,693	Inc.	148,404

The Roberson Quadruplex Between New York and Buffalo.

Tests of the Roberson quadruplex, described in our issue of September 30, 1897, are being carried on continuously by the Western Union Telegraph Co., from New York as a center. The Roberson quad having proved so successful between New York and Washington, it was early in December tried on the line between New York and Buffalo, a distance of 430 miles. It has been working almost continuously since then and with very satisfactory results.

Long Distance Telephony and the Railroads.

Wiht regard to the effect of the long distance telephone on railroad passenger patronage, that shrewd observer, Mr. Chauncey M. Depew says:

"There is no doubt that the long-distance telephone is affecting short-distance railroad travel to a considerable extent. By short-distance travel I mean that within a hundred miles or less of the cities. One reason is that manufacturers who used to communicate with their offices and stores in the cities by messengers or by some member of the firm or corporation going to and fro frequently, now find that they can do business as well and with a saving in time by using the telephone. Then the country merchant who used to go to town once a week to replenish his stock finds that he can replenish it daily, if need be, by using the telephone, according to the demands of his business. Thus he does not have to carry so large a stock, but lets the wholesaler carry it for him. His wife knows this, and so he no longer has a good excuse for going to town often.

"These I look on as the regular sources of railroad travel that are cut off by the long-distance telephone. Now for the irregular sources. Social communications over short distances are now performed to a large extent by means of the telephone. The shopping business is another important factor. Take people living within 25 or 30 miles of a good-sized city, they mostly have telephones in their houses, and, instead of going in for shopping purposes at short intervals, they call up the stores by telephone, and only go shopping in person occasionally. Then if we take places like Syracuse, Rochester, Utica, Albany and their outlying districts we find that a good deal of business is done by telephone, and much railroad travel for short distances is saved to the people.

"All these things taken together show that a large amount of business is thus cut off from the railroads. But the increase of population is making up for the loss thus occasioned. In other words, the telephone keeps the factories at the little places, while the main offices are in the larger ones. It is so with all inventions: at first they seem to be injurious to certain interests, but ultimately they prove of advantage all around."

Some Views on the Municipal Plant Situation in Detroit.

BY GEORGE E. FISHER, E. E.

YOUR issue of the 23d ult., under "Municipal Affairs" contains an article evolved from the mind of Mr. William H. Fitzgerald, manager of the Detroit Electric Light and Power Company, which article is so misleading that it seems an injustice to allow such an elaborate misrepresentation of actual facts to go unchallenged, and if such an article were published in a Detroit paper, would make the writer of it the laughing stock of the city.

The writer is very familiar with all of the incidents leading up to the installation of what we consider the finest municipal lighting plant in the United States, but I do not reply with the idea that it will counteract the influence his article might have to "prevent other cities from following our example."

He states that "Until the tide of feeling favoring municipal ownership struck us the service given the public was generally satisfactory." This statement is so decidedly erroneous, especially as applied to the company which he represents, that the twelve or more victims of this same management who met death prematurely should arise from their graves and expostulate. Vulgarly speaking, the service was "rotten," a statement which every unprejudiced citizen will substantiate. The Detroit Evening Journal of September 15, 1894, publishes a list of the men killed by the Detroit Light and Power Company's plant under Mr. Fitzgerald's management, and subsequent events under municipal ownership clearly demonstrates that either this company were operating a very inferior plant or it was being operated by a very inferior management. Why did not the gentleman think of the large investment of the stockholders in the Brush Company (former contractors), who were also among "Detroit's largest taxpayers," when he assisted in organizing a company to compete with them, thereby placing his former employers "in such a position to have their property sacrificed."

Personally I am not an advocate of municipal lighting, except under certain conditions which exist locally, and if any municipal corporation was justified in municipal ownership, the City of Detroit was the one. Why?

The contract price with the Detroit Company was $132.41 per light per annum, which, considering the large number of lights and other local conditions, the most antagonistic citizen will admit was an excessively high price. Prior to the expiration of the three years' contract, R. T. McDonald, manager of the Ft. Wayne Electric Company, who was largely interested in the Detroit Company, obtains control of the Brush Company, the former contractors, and assumes its management, securing the purchase price by an issue of bonds to the original stockholders, thereby preventing competition from that source when the three year contract expired and incidentally settles pending litigation on tower patents. At that time there were two sets of towers in the city, and in order to relieve future contractors of the burden of putting up towers at an enormous expense, bids were received by the City Controller for them. Did either of these two companies offer to sell their towers? No. Mr. Fitzgerald came into the Controller's office (the writer being present), and when asked for their bid on towers, smiled sardonically and stated they had no towers to offer.

The writer with other Detroit people who also "share the burden of taxation" discovered, through a prominent attorney, an old English patent on towers, which satisfied us that the patents controlled by Mr. R. T. McDonald and his colleagues were valueless and we offered towers to the city, covering our bid with a certified check for the amount required by the specifications. These gentlemen probably did not know that one of the objects in receiving bids on these towers, was to expose the collusion between the two companies, and from that time on Mayor Pingree, Controller Black, and others, left no stone unturned to break up this local combination and the carefully-laid plan to mulct the City of Detroit for thousands of dollars annually.

Now let us see why Mr. Fitzgerald could not sell his plant to the city.

The Commission consisted of six of Detroit's best citizens, and one, and only one, was ever interested in the Brush Company. That was J. L. Hudson, who was not a stockholder at the time he was appointed, as all of the stock was controlled by Mr. R. T. McDonald. Mr. Fitzgerald's assumption and presumption in criticizing the acts of a man like we all know J. L. Hudson to be is misplaced, and the writer is very positive that if Mr. Hudson actually owned controlling interests in the old company he would have sacrificed it all rather than perform a dishonest act as an honorable member of the Public Lighting Commission.

What part of the plant could the City of Detroit have purchased and secure an installation equal to what it is now operating? The steam plant? No, as we do not think it would have been wise to have installed second-hand boilers and engines, even if they were of "modern" type, nor could they have afforded to have bought the dynamos, as they were small units and modern practice in large plants proves that the large units are preferable. Surely they could not expect the city to buy the Fort Wayne rack feed lamps which were never adapted for outdoor service and have since been abandoned by the company themselves. The underground system has also been abandoned with the exception of a few small pieces and was a complete wreck at the time the city was negotiating for a plant, most of the circuits in the underground territory being run overhead by Mr. Fitzgerald's company.

With a record of seven men killed, surely it would be unfair to assume that Mr. Fitzgerald was personally responsible for this, so it must have been the plant, and that in itself would justify the city in letting it severely alone; and it was not until the other arrangements had been practically agreed upon that the Detroit Electric Light and Power Company seemed to realize that they were beaten and that their scheme was knocked out.

From figures that I gather, including interest on bonds, wear and tear on plant, etc., it has cost the City of Detroit $89.42 per light per annum, a saving of over $43.00 per light or $77,000.00 per annum. This is quite satisfactory to the citizens of Detroit, and we do not think any twisting of figures or an evasion of facts, notwithstanding this gentleman's efforts, will convince the citizens of Detroit or in "the many cities throughout the country regarding the lighting of Detroit" that we did not achieve a magnificent success, and that the service is so far superior to that rendered by the Detroit Light and Power Company, that comparison is impossible.

I might add that since the time this fight was settled, the Fort Wayne Company have stepped down and out, and the old Brush Company is now doing a successful business at the old stand, being in the hands of its original owners. How would private consumers be treated now if McDonald and Fitzgerald's scheme had worked, and what an elegant thing another contract would have been for these gentlemen; while now we are getting good service in our city lighting and genuine competition in commercial lighting.

How Municipal Authorities Protect Public Health.

The State Board of Health cannot get at the actual number of cases of contagious disease in the State when over 100 places refuse figures. The law of 1893 fixed a penalty, which was that if the Board of Health of a city or town refused or neglected to furnish the notice, it should forfeit its claim upon the State for reimbursement where it had expended money for a person ill with such a disease, who had no money or no settlement. In all such cases the money is paid upon the approval of the bill by the State Board of Lunacy and Charity. The Board of

Health has now arranged with the Board of Lunacy and Charity to be notified whenever such a claim comes in from a city or town which does not furnish notices, and the auditor will be notified in turn of such neglect before the claim is paid. —Boston Transcript.

Public Control, Ownership or Operation of Municipal Franchises?—II.

With Special References to Electric Lighting.*

By R. R. BOWKER,

(Vice-President and General Manager New York Edison Co.)

VARIANTS IN COMPARATIVE STATISTICS.

IN such a comparison of industrial services, several classes of variants must be taken into account—as between industries, as between localities, as between complete or imperfect statistics and as between different methods of statement. Most of the tabulated returns put forward by those not acquainted with the respective industries furnish no real basis of comparison and are misleading. In England, however, the Board of Trade requirements afford a basis of comparison more nearly adequate, and it is gratifying that the United States Bureau of Labor is entering upon a careful comparison in the lighting industries, which has been planned to cover very nearly all the variant conditions.

As to variants between industries: Water can be stored cheaply for use at any time and suffers no loss except a slight evaporation and leakage. Gas supply for ten hours can be stored cheaply, with perhaps 10 per cent. loss in gasometer storage and in distribution through mains. The price is, therefore, usually the same to all consumers and at all hours. Electricity must be produced at the instant of demand, unless stored at a loss of 25 per cent. in costly storage batteries. Of the generating machinery required at the hours of maximum use, a quarter is utilized less than 100 hours in a year, and the loss in transmission reaches from 10 per cent. to nearly 40 per cent., the last on alternating systems which energize house converters through the whole 24 hours. The price, therefore, differs greatly with the conditions of supply, and electric current can profitably be supplied through 10 hours at a third the price charged for the "maximum" two hours. Street cars and suburban trains are chiefly in demand morning and evening. The telegraph can defer part of its business as night messages; but the telephone must instantly supply each demand and, contrary to most other industries, the operating cost in a large system is greater than in a small one, since a "central" of 50 subscribers need make but 2,500 combinations, while one with 5,000 subscribers must provide for 25,000,000 combinations at greatly increased cost. Even within city limits the cost of service is somewhat greater with distance, but it does not seem fair that a customer to whom the source of supply is not near should be charged more than one close by, and in American cities street car fares as well as gas and electricity charges are usually generalized into a uniform rate. In the early days of postal facilities a pony express letter to San Francisco was a costly affair, but a 2-cent stamp now carries a letter either across the street in New York or across the continent to San Francisco.

As to variants between localities: The density of population, not only in a city, but in the area supplied, is an important variant in cost. Fuel and water costs vary greatly. In New York hard "pea" coal costs about $3 delivered, or $2.50 "alongside" dock; in Chicago soft factory coal is delivered to riverside factories at about $1.10. Some Western cities use natural gas or oil. Ratings are different in different localities, as in the candle power of gas and even in the definition of candle power, which is different on the Continent from that in England and America. In London electric incandescent lamp "equivalents" are usually based on the 8 candle power lamp; in Paris, on the 10 candle power lamp; in Berlin and American cities, on the 16 candle power lamp. European prices for electric lighting usually do not cover the installation and renewal of incandescent lamps. American prices usually include them. The standard arc lamp of 425 watts in the arc or 450 watts at terminals (10 amperes of 45 to 50 volts) is nominally of "2,000 candle power;" but this lamp is spoken of in the New York contract as of "at least 1,000 candle power," and entered in National Electric Light Association returns as "1,200 candle power;" while the high tension arc light rated in Brooklyn as 1,200 candle power is of 325 watts, or 7 amperes. Overhead supply is much cheaper than subway supply, the New York rentals equaling $40 to $50 per lamp where street lighting only is supplied. Some of these latter variants are really variants in terminology, that is, in the different use of words or names in different places.

There are usually many variants in the comparisons, especially tabulated comparisons, between municipal returns and those of private corporations. A private corporation pays taxes and a municipal industry does not. Interest, maintenance and depreciation charges are often overlooked in municipal industries. Legal charges are usually in municipal industries charged to the corporation counsel's office and not to the industry. General expenses, such as auditing and the cost of the central administration of the city, are commonly among the many forgotten elements in municipal accountings. The return of the private corporation to the State or city in indirect ways is usually not credited in such comparisons. In Paris, for instance, the price of gas should be considered for comparison as $1.35 per thousand cubic feet, because 28.6 cents of the price—$1.64—is paid back to the citizens through the municipality or the national taxes.

A company supply cannot be compared with municipal supply unless the charter also is for an entire city exclusive and permanent, as is usual under municipalization and is possible, under proper safeguards, in chartered companies.

*This paper is written from the point of view of the economist and citizen, but with the data and experience gained as the executive of the New York Edison Company. To my mind, this should not involve opposition of interests; as he most serves his party who best serves his country, so he most serves the interest of a public-service company who best serves the public. I mention the relationship, however, to forewarn readers of any unintentional bias. It is difficult for any outside the business cited, in an academic discussion, to obtain real bases of comparison.—Reprinted by permission from Municipal Affairs, the Reform Club Quarterly.

Municipal Plant Politics at Thompsonville, Mich.

The recent village election at Thompsonville, Mich., was won by the anti-improvements faction. Since then electric light and water plants, established by the previous administration, are alleged to have been neglected and now the water works have shut down for an indefinite period, leaving the town without fire protection. It is charged that there is a shortage of $490 in the village treasury.

Taunton, Mass., Municipal Plant Afraid of Competition.

Nomus Paige, manager of the Taunton municipal lighting plant, has submitted his first report to Mayor Fish. The report in the future will be annual. At present it covers only the period from July 1 to the close of the financial year. The whole report is of interest, showing as it does the results of the experiment into which the city entered this year. One of the most striking features of the report is that, by leaving out interest and depreciation allowances, the commercial work is made to show sufficient revenue to meet all operating charges, maintain 116 lights free of cost, and leaves a balance of $334.04. Mr. Paige recommends the wiring of school houses for the system and the inauguration of meters in the commercial service. He deprecates the action of the aldermen in granting a franchise to a competing company last September, and thinks it will prove a dangerous mistake. The plant now furnishes 164 commercial customers, an increase of 11 since July 1. There are 5,000 incandescent lamps in use, 111 arc lights and 80 horse power in motors. The plant includes a four-story, brick building, 5,000 incandescent and 520 arc light dynamo capacity, 100 horse power in motor power, a boiler capacity of 450 horse power, and an engine capacity of 665 h. p., 65 miles of street wire and 800 poles.

SOMERVILLE, MASS.—A resolution in favor of a municipal electric lighting plant has been voted down by the aldermen, by a vote of 5 to 3, and in the Council by a vote of 8 to 7.

MR. D. J. McCAZINE, manager of the Gunnison, Cal., Gas and Water Company, writes us: "I have found The Electrical Engineer a welcome visitor during the past year."

MECHANICAL

The Comparative Cost of Steam and Electric Power.—V.

BY IRVING A. TAYLOR.

ELECTRIC POWER.

THE commercial efficiencies of the electric motors may be taken as follows:

CASE I.—10 h. p. motor, 83 per cent.; 25 h. p. motor, 88 per cent.; 50 h. p. motor, 90 per cent.; 100 h. p. motor, 91 per cent.

CASE II.—10 h. p. motor, at 100 per cent of load, 83 per cent.; at 80 per cent. of load, 82 per cent.; at 50 per cent. of load, 78 per cent.; at 30 per cent. of load, 70 per cent. 25 h. p. motor at 100 per cent. of load, 88 per cent.; at 80 per cent. of load, 87 per cent.; at 50 per cent. of load, 82 per cent.; at 30 per cent. of load, 75 per cent. 50 h. p. motor, at 100 per cent. of load, 90 per cent.; at 80 per cent. of load, 90 per cent.; at 50 per cent. of load, 85 per cent.; at 30 per cent. of load, 77 per cent. 100 h. p. motor, at 100 per cent. of load, 91 per cent.; at 80 per cent. of load, 91 per cent.; at 50 per cent. of load, 86 per cent.; at 30 per cent. of load, 78 per cent.

TABLE 5 A.—TOTAL YEARLY COST OF ELECTRIC CURRENT.

CASE I.

H. P. of motor	10	25	50	100
B. H. P. H. yearly output	30,800	77,000	154,000	308,000
Efficiency of motor	.83	.88	.90	.91
E. H. P. H. yearly input	37,100	87,500	171,000	338,500
Cost per E. H. P. H.	$.03	$.03	$.03	$.03
Cost of yearly current	$1,113	$2,625	$5,130	$10,155

CASE III.—10 h. p. motor, at 100 per cent. of load, 83 per cent.; at 40 per cent. of load, 74 per cent.; at 15 per cent. of load, 61 per cent.; at 10 per cent. of load, 54 per cent. 25 h. p. motor, at 100 per cent. of load, 88 per cent.; at 40 per cent. of load, 79 per cent.; at 15 per cent. of load, 64 per cent.; at 10 per cent. of load, 58 per cent. 50 h. p. motor, at 100 per cent. of load, 90 per cent.; at 40 per cent. of load, 82 per cent.; at 15 per cent. of load, 67 per cent.; at 10 per cent. of load, 60 per cent. 100 h. p. motor, at 100 per cent., 91 per cent.; at 40 per cent, 82 per cent.; at 15 per cent., 67 per cent.; at 10 per cent. of load, 60 per cent.

TABLE 5 B.—TOTAL YEARLY COST OF ELECTRIC CURRENT.

CASE II.

10 H. P. MOTOR.				
B. H. P. output	3	5	8	
Efficiency of motor	.70	.78	.82	
E. H. P. input	4.28	6.41	9.76	
Hours per day at above rate	5	3	2	
E. H. P. H. per year				18,510
Cost of yearly current at $.048 per E. H. P. H				$888
25 H. P. MOTOR.				
B. H. P. output	7.5	12.5	20	
Efficiency of motor	.75	.82	.87	
E. H. P. input	10	15.25	23	
Hours per day at above rate	5	3	2	
E. H. P. H. per year				43,650
Cost of yearly current at $.03 per E. H. P. H				$1,309
50 H. P. MOTOR.				
B. H. P. output	15	25	40	
Efficiency of motor	.77	.85	.90	
E. H. P. input	19.5	29.4	44.5	
Hours per day at above rate	5	3	2	
E. H. P. H. per year				84,600
Cost of yearly current at $.03 per E. H. P. H				$2,538
100 H. P. MOTOR.				
B. H. P. output	30	50	80	
Efficiency of motor	.78	.86	.91	
E. H. P. input	38.5	58.1	87.9	
Hours per day at above rate.	5	3	2	
E. H. P. H. per year				167,000
Cost of yearly current at $.03 per E. H. P. H				$5,010

The expense rates per year will be as follows: Insurance, 1 per cent. The cost of rent for the space occupied will often be nothing, as an electric motor cannot in any sense be considered a nuisance; but in those cases where it should be included, it will seldom be more than the following amounts: 10 h. p. motor, $15 per year; 25 h. p. motor, $37.50 per year; 50 h. p. motor, $75 per year; 100 h. p. motor, $150 per year. Interest on plant will be taken at 6 per cent., and the depreciation and repair account at 8 per cent.

Attendance, 10 and 25 h. p. motors, $16; 50 and 100 h. p. motors, $21.

Supplies, 10 and 25 h. p. motors, $10; 50 and 100 h. p. motors, $15.

The following may be taken as the cost of motors, set and substantially wired: 10 h. p. motor, $315; 25 h. p. motor, $525; 50 h. p. motor, $875; 100 h. p. motor, $1,700.

TABLE 5 C.—TOTAL YEARLY COST OF ELECTRIC CURRENT.

CASE III.

10 H. P. MOTOR.				
B. H. P. output	1	1.5	4	
Efficiency of motor	.54	.61	.74	
E. H. P. input	1.85	2.46	5.41	
Hours per day at above rate	4	4	2	
E. H. P. H. per year				8,642
Cost of yearly current at $.054 per E. H. P. H				$467
25 H. P. MOTOR.				
B. H. P. output	2.5	3.75	10	
Efficiency of motor	.58	.64	.79	
E. H. P. input	4.31	5.87	12.67	
Hours per day at above rate	4	4	2	
E. H. P. H. per year				20,346
Cost of yearly current at $.048 per E. H. P. H				$977
50 H. P. MOTOR.				
B. H. P. output	5	7.5	20	
Efficiency of motor	.60	.67	.82	
E. H. P. input	8.33	11.2	24.4	
Hours per day at above rate	4	4	2	
E. H. P. H. per year				39,098
Cost of yearly current at $.03 per E. H. P. H				$1,173
100 H. P. MOTOR.				
B. H. P. output	10	15	40	
Efficiency of motor	.60	.67	.82	
E. H. P. input	16.67	22.4	48.8	
Hours per day at above rate	4	4	2	
E. H. P. H. per year				78,195
Cost of yearly current at $.03 per E. H. P. H				$2,346

Cost of current in cents per electrical h. p. hour: 8,400 to 12,000 h. p. h. consumption per year, 5.4 cents; 12,000 to 24,000 h. p. h. consumption per year, 4.8 cents; 24,000 to 36,000 h. p. h. consumption per year, 4 cents; 36,000 or more h. p. h. consumption per year, 3 cents.

This item of cost of current is the main one in the electric power account, and is somewhat subject to variation in different localities. In large cities, where the peak of the station load curve occurs after 5.30, or especially after 6 p. m., the above prices, or even a trifle lower, will probably obtain.

TABLE 6.—COST OF ELECTRIC POWER.

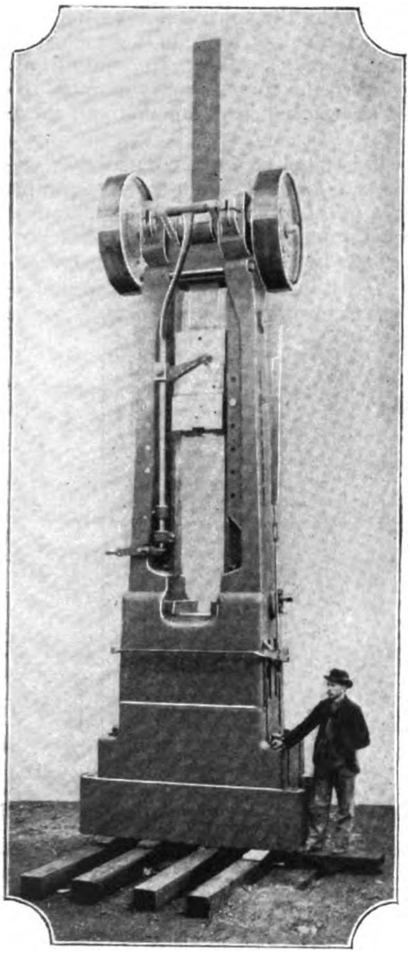
H. P. of motor	10	25	50	100
Plant cost	$315.	$525.	$875.	$1,700
Insurance	3.15	5.25	8.75	17
Rent	15.	22.50	35.	60
Interest	18.90	31.50	52.50	102
Depreciation and repairs	25.20	42.	70.	136
Attendance	16.	16.	21.	21
Supplies	10.	10.	15.	15
Total fixed charges	88.25	127.25	202.25	351
CASE I.				
Total fixed charges	$88	$127	$202	$351
Cost of current	1,113	2,625	5,130	10,155
Total yearly cost	1,201	2,752	5,332	10,506
B. H. P. H. per year	30,800	77,000	154,000	308,000
Cost, cents per B. H. P. H	3.9	3.58	3.46	3.41
CASE II.				
Total fixed charges	$88	$127	$202	$351
Cost of current	888	1,309	2,538	5,010
Total yearly cost	976	1,436	2,740	5,361
B. H. P. H. per year	14,168	35,420	70,840	141,680
Cost, cents per B. H. P. H	6.9	4.06	3.87	3.79
CASE III.				
Total fixed charges	$88	$127	$202	$351
Cost of current	467	977	1,173	2,346
Total yearly cost	555	1,104	1,375	2,697
B. H. P. H. per year	5,544	13,860	27,720	55,440
Cost, cents per B. H. P. H	10.02	7.98	4.96	4.87

Even in those cases where the station load curve is unfavorable the motor load holds so nearly steady for such a large number of hours per day that it is a very remunerative one, and though the cost of current will probably be somewhat greater, it should not be very much so. Taking the average motor efficiency over a large range of loading at 75 per cent., the effect of a variation in either direction of the cost of current will be to make the total cost per brake h. p. hour vary in the same direction, and at 1⅓ times the rate; that is, for every cent increase or decrease in the cost of current per electrical h. p. hour the cost of power per brake h. p. hour would increase or decrease about 1⅓ cents.

The total cost of electric current in dollars per year, will

be found in Tables 5 A, B and C, and the total cost of electric power, in cents per brake h. p. hour, which is the summation of all the foregoing items of expense, is computed in Table 6.

Billings & Spencer's Largest Drop Hammer in the World.



MESSRS. BILLINGS & SPENCER, the well kown manufacturers of drop forgings, have just completed and put in use what is probably the largest drop hammer in the world. They were led to the construction of this unique tool by the need for a device that would displace a large amount of metal at a single blow.

In such articles as very large sprocket wheels, deep cup-shaped specimens having considerable metal in them, it was thought to be more economical to bring these forms to the desired shape under one or two blows with a heavy drop than to depend upon a hammer of smaller capacity and repeated blows. Besides being more economical, the former method obviates many difficulties attending the displacement of large masses of metal under repeated light blows. The hammer, therefore, marks an innovation, not only because of its magnitude, but also because of the work expected of it. Another change is in the foundation, in which every attempt has been made to secure absolute rigidity and to provide a mass practically immovable, even under the greatest stroke.

The principal dimensions of the hammer are as follows:

Weight of hammer	3,000 pounds.
Weight of base	60,000 pounds.
Total weight of base	90,000 pounds.
Size of base at bottom	45 x 90 inches.
Length of uprights	11 feet 3 inches.
Between ways on uprights	18 inches.
Height from floor to top of pulleys	16 feet 9 inches.
Total height required above floor to operate machine	23 feet
Diameter of pulleys	48 inches.
Face of pulleys	10 inches.
Distance between pulleys	48 inches.
Revolutions per minute	80
Extreme fall	6 feet 4 inches.
Shortest automatic fall	31 inches.
Bottom of casting to top of pulley	21 feet 9 inches.

The lifting rolls placed at the top of the frame are automatically operated by the hammer and may be automatically shifted to effect, at any desired point of the upward movement of the hammer, a gradual release of the rolls from the lifting board, and also to effect, at any required point in the descent of the hammer, a gradual and positive engagement of the rolls with the lifting board. The effective stroke of the hammer can also be regulated as demanded by different kinds of work. The roll shifting mechanism is automatically held in its open position, and is released by the descending movement of the hammer so as to bring the rolls in engagement with the lifting board.

One of the most interesting features of this tool is the foundation. The excavation was carried down in the hammer shop of the works, where the tool is finally to be located, until hard pan was encountered. Upon this was placed a bed of concrete measuring 9 x 5 feet and having a depth of 3 feet. The concrete was composed of three of sand, one of cement and one of broken stone. On this was built up a box formed of channels placed one above the other and having a depth of 45 inches, and measuring 4 feet 1 inch by 7 feet 10 inches. In building this foundation the method was such that before the lower bed of concrete had hardened the box was placed in position and then filled with concrete. The channels measured 15 inches in depth. Through the foundation extended tie bolts, which served to hold the lower section of the base proper of the hammer. This base is composed of three sections, weighing about 20,000 pounds each. They are held together by bolts and are prevented from sidewise movements by a groove and tongue arrangement and center pin. Between the upper surface of the concrete base and the lower surface of the lowest cast iron section is interposed a sheet of lead ¼ inch thick. This serves the purpose of insuring an even and perfect contact of every portion of these two surfaces, and acts to obviate any evil results that might occur from unequal contact, or contact only in certain portions.

The results of tests made with this new drop hammer have already proved its vast superiority.

Exhaust Steam Heating.

IN your issue of December 16 "Le Chat" seems to argue against the use of exhaust steam under all conditions. At any rate, he does not point out how existing errors could be easily overcome, so that the proprietor of a power establishment can utilize 85 per cent. of the steam he generates for heating, which he cannot utilize in his engine, and only a small part of which can be absorbed in his feed water.

"Le Chat" assumes a back pressure of 12.2 pounds per square inch in a given case, and then charges this against 25 per cent. of the power of the engine, which it has to overcome. He should point out that the pipes in the building are too small, and which, if properly proportioned, should produce a back pressure of say two pounds. That would reduce the force of his argument to a minimum, if it had any force at all. So-called back pressure on an engine is an addition of so much, be it 2 pounds or 12 pounds, to the atmosphere against which the engine must work. Did "Le Chat" ever think so far as to see that if the pressure in the boilers supplying the engine was increased by an amount equivalent to the back pressure in the heating system the engines would do the same amount of work as before, and there would be no "straining of the engine," either. And the owner's pocketbook would be strained by just the extra amount of coal that the higher pressure would require above the normal. This would be but a small item in all cases where the fitting in the building was properly constructed.

"Le Chat's" "yellow dog" argument in regard to the quality of heat supplied by the exhaust steam to the radiators shows that he is hardly aware of the fact that a given steam pressure means a certain temperature of the steam. It makes no difference whether it be "live steam" or "exhaust steam." This law holds good always. House heating is, or should be, done with low pressure. From which it follows that exhaust steam at a heating pressure of one pound or more is just as efficient as steam direct from a boiler at the same pressure.

The fair conclusion is, then, if a very little brain work is employed, that the power plant may not only heat its own feed water if desired, but may do a considerable amount of heating besides, without impairing the efficiency of the engine.

SIC 'EM.

NEWS AND NOTES

The Pfatischer Electrical Steering Gear.

ON all large Atlantic liners and warships the rudder is worked by power such as steam or hydraulic. The steering engine must be located in proximity to the rudder post so as to avoid expensive power transmitting machinery such as chains, ropes or shafting, and the starting, stopping and reversing of the rudder engine must be controlled from the bridge or pilot house, in all cases several hundred feet distant from it. The valve controlling the engine could, of course, be operated by means of shafting or ropes from the pilot house, but such mechanical transmission gears work very stiffly and require too much manual labor. To make steering very easy and more accurate electricity has been introduced of late.

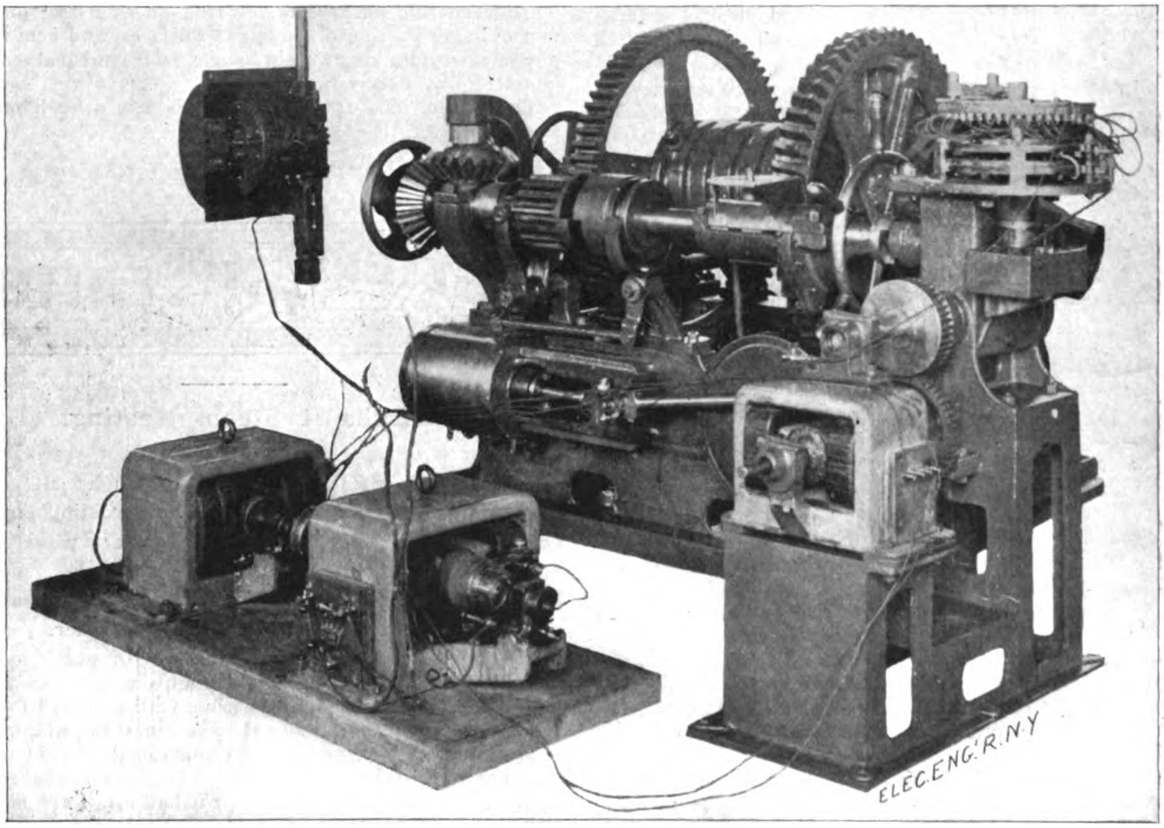
In adopting electricity for this purpose Mr. M. Pfatischer, of Philadelphia, has retained the mode of steering that has been followed for years. This method consists in turning a hand wheel which revolves a certain number of revolutions for bringing the rudder from hard a-port to hard a-starboard. The quartermaster or sailor working the steering wheel knew by giving it a certain amount of turn that his rudder would move accordingly; in adapting electricity for operating the valve of the steering engine, this modus operandi has not been changed.

Assuming now that the man operating the wheel has turned it, for instance, one-quarter of a revolution; the electric current will immediately begin to set in motion the small electric motor located at the steering engine, which motor turns the automatic shaft operating the valve of the engine. The person operating the steering wheel has no need to give any thought of closing or changing any circuit of the electric current; all that he does is to move the wheel in such direction as he desires the rudder to move.

As soon as the rudder has moved a sufficient distance corresponding to the amount of turn given to the steering wheel, the electric current is stopped automatically, therefore stopping the motor which operates the valve and which in turn stops the steering engine. The automatic control and adjustment of the electric power takes place no matter how far and in what direction the wheel is moved, the rudder following in direction and degree exactly the amount of movement of the steering wheel on bridge or pilot house.

The electric working principle of the apparatus is as follows: In turning the steering wheel through any angle an electric balance is disturbed which is only brought to equilibrium again by the rudder following to the corresponding point. No electric circuits are opened and closed in doing this and there is therefore no sparking.

The apparatus, which is illustrated in the accompanying engraving, consists of a rheostat forward and a corresponding rheostat aft at the engine, a ½ h. p. electric motor operating the valve gear and a small motor-generator. The function of the motor-generator is to produce the special current needed for the motor operating the valve. The primary current is taken from the ship's circuit and only a single wire is run to connect the two rheostats forward and aft. This single wire forms the balancing circuit, which is included in the field circuit of the motor driven generator.



THE PFATISCHER ELECTRIC STEERING GEAR ON BOARD THE U. S. BATTLESHIP IOWA.
(Built by Messrs. Williamson & Co., Philadelphia.)

Assuming now that the center arm of the forward rheostat—shown in the upper left hand corner—is moved one way or the other by the steering wheel, the electric balance is immediately disturbed, causing a small current to flow in the balancing wire. This current is transformed up to sufficient magnitude to drive the motor operating the valve and also to operate the center dial arm of the after rheostat, moving it in the same direction as the forward rheostat arm was moved. As soon as the after dial arm has reached the corresponding point the current is again balanced and the motor stops.

In transmitting the power of the small motor for operating the valve gear of the engine there has been introduced a safeguard in the form of a spiral spring device to prevent the stalling of the electric motor in case the steam engine breaks down or steam is turned off or turned on only gradually. These springs are strong enough to move the valve under

ordinary circumstances, but if occasion should arise in which the valve sticks, the engine breaks down or does not run at the speed to which the motor tries to make it travel, the power given out by the motor would then enter the springs and as fast as the engine runs the springs come back to their normal position.

If the valve does not start, the springs can be compressed, allowing the motor to travel hard over, compressing the springs; and then if the valve should start to move and the engine follow up, the springs would come back to the normal position as soon as the engine has reached the corresponding position to which the wheel in the pilot house is placed.

This electric steering apparatus illustrated is built by Messrs. Williamson Bros., engineers, of Philadelphia, and has been introduced on the United States battleship Iowa and on the monitor Miantonomoh, as well as on several Atlantic liners. The lowering of the records of several of the latter is acknowledged to be due to the use of this steering apparatus, which enables the vessels to be kept more accurately to their course than was possible by the older method.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued December 28, 1897.

Alarms and Signals:—

ELECTRICAL SIGNAL BELL FOR STREET CARS. J. P. Orr, Pittsburg, and T. F. Galvin, McKeesport, Pa., 596,085. Filed Aug. 3, 1896. Operated by electromagnets and automatically controlled.

SIGNALING CIRCUIT FOR FIRE AND POLICE SYSTEMS. A. Barrett, Kansas City, Mo., 596,134. Filed Sept. 9, 1897. Emergency calls are transmitted over the second wire, and the two wires are used as a telephonic circuit.

ELECTRICAL SIGNALING SYSTEM. J. P. Buchanan, Boston, Mass., 596,201. Filed Dec. 27, 1893. Block signal system designed to be operated by passing trains.

ELECTRIC SIGNALING SYSTEM. A. J. Wilson, Port Chester, N. Y., 596,226. Filed Dec. 21, 1895. Block signal system for railroads.

FIRE TELEGRAPH REPEATER. F. S. Skelton, Newton, Mass., 596,250. Filed July 3, 1893. Employs a supplementary battery and suitable contact devices connected to the several circuits for connecting the supplementary battery in circuits successively and momentarily.

ELECTRIC CALL BOX SYSTEM. W. T. Budds, Charleston, S. C., 596,356. Filed July 14, 1897. Details of construction.

MAGNETO ELECTRIC SIGNALING APPARATUS. A. S. Williams, Newton, Mass., 596,418. Filed June 5, 1897. Combines with the field magnet and armature, a key and a motor-spring adapted to successively move the armature in opposite directions, and a detaining device controlling and acting to delay the operation of the spring.

ANNUNCIATOR. A. D. Neale, Kittanning, Pa., 596,426. Filed March 17, 1897. Adapted to indicate a telephone call, an automatic drop-annunciator being released so that if the person called is absent the annunciator will inform him of such call upon his return.

SIGNALING CIRCUIT. J. J. O'Connell, Chicago, Ill., 11,645. Reissued. Filed March 3, 1896. Comprises a system in which the signal sending appliances at one station when actuated remain in their working position until the attendant at the other station takes proper action in response thereto.

Conductors, Conduits and Insulators:—

UNDERGROUND JUNCTION BOX FOR ELECTRIC CONDUCTORS. W. F. Bossert, Utica, N. Y., 596,229. Filed Feb. 17, 1897. Consists of a body portion, an insulating bushing held therein, a cap, an insulator bushing held therein and an elastic packing between the adjacent ends of the bushings.

Dynamos and Motors:—

SECURING DEVICE FOR COVERS OF DYNAMO ELECTRIC MACHINES. N. C. Bassett, Lynn, Mass., 596,135. Filed March 27, 1897. Designed for railway motors.

ARMATURE WINDING AND COIL. A. F. Batchelder, Schenectady, N. Y., 596,136. Filed Sept. 15, 1897. Embodies a coil having the sides to be disposed on the armature face united at least at one end by three end portions, two of which are involutes offset from one another, and the third a spiral.

DETACHABLE LAMINATED POLE PIECE FOR DYNAMO ELECTRIC MACHINES. H. Geisenhoner, Schenectady, N. Y., 596,152. Filed Oct. 11, 1897. Comprises a support provided with slots extending parallel to the shaft of the machine, laminated detachable pole pieces having projections inserted in the slots and held therein by expansion.

FOUNDATION FOR GENERATOR FRAMES. S. H. Short, Cleveland, O., 596,280. Filed March 13, 1897. Masonry foundations for large generator frames.

DYNAMO ELECTRIC MACHINE. P. W. Power, Pittsfield, Mass., 596,306. Filed Feb. 12, 1896. Comprises a rotating inductor having laminated polar projections separately fastened to the inductor core by dovetail fastenings.

Electro-Metallurgy:—

PROCESS OF AND APPARATUS FOR EXTRACTING METALS FROM ORES. W. E. Inglis, Mount Vernon, N. Y., 596,458. Filed April 20, 1896. A process of extracting tin from a refractory ore, consisting in liberating the sodium from a fused sodium compound, by the action of an electric current, and causing the freed nascent sodium to separate the tin without fusing it.

Measurements:—

INDUCTION WATTMETER. E. Thomson, Swampscott, and W. H. Pratt, Lynn, Mass., 596,190. Filed Sept. 7, 1897. Designed for single phase alternating current circuits. Details of construction.

ELECTRIC CURRENT METER. R. P. Wilson, London, England, 596,283. Filed March 24, 1897. Consists of a device by which current used at different periods of a day may be separately metered and automatically registered.

Miscellaneous:—

APPARATUS FOR ELECTROLYTICALLY PRODUCING ALKALIS. J. Hargreaves, Widnes, England, 596,157. Filed March 16, 1896. Provides the chamber with a boundary composed of a diaphragm impermeable as a filter in contact with a cathode of open texture, directing against the cathode a jet of steam which condenses and washes away the cathion.

ELECTRIC HEATER. H. Helberger, Munich, Germany, 596,160. Filed April 29, 1896. Comprises a body of conducting material, wire wound thereon, beads of refractory substance on the wire and a layer of insulating material outside the wire.

THERMOMETER. L. E. Hunt, Somerset, Ky., 596,162. Filed Sept. 21, 1896. A mercurial thermometer designed to close a circuit by the expansion of the mercury.

LEAD FOR ELECTRICAL SOUNDERS. J. Mohs, Brandenburg, Germany, 596,172. Filed Sept. 3, 1896. Comprises a body, a pair of contact devices, a shoe pivotally connected to the front end of the body and extending beneath, and means operated by the movement of the shoe for closing a circuit.

ELECTRIC GAS-LIGHTING DEVICE. A. L. Bogart, New York, and Le Roy S. White, Waterbury, Conn., 596,236. Filed May 7, 1897. Designed for Welsbach burners.

ELECTRIC BICYCLE. H. W. Libbey, Boston, Mass., 596,272. Filed Nov. 8, 1895. Propelled by a motor the current for which is supplied from primary batteries carried on the bicycle.

ELECTRIC BICYCLE. H. W. Libbey, Boston, Mass., 596,273. Filed Dec. 14, 1895. Similar to above.

ELECTRIC BICYCLE. H. W. Libbey, Boston, Mass., 596,274. Filed Dec. 14, 1895. Similar to above.

Railways and Appliances:—

ARRANGEMENT FOR PREVENTING ACCIDENTS ON RAILWAYS. H. Biermann, Breslau, Germany, 596,047. Filed May 21, 1897. Employs forked frames provided with rollers and surrounding the wheels-axles and engaging with the rails in case of wheel, axle or spring breaking with an electric circuit in the train and connected with safety and alarm apparatuses.

ELECTRIC RAILWAY. E. C. Crocker, Bridgeport, Conn., 596,054. Filed April 23, 1897. Comprises a supply conductor, a third rail consisting of insulated sections, and a power collector carried by the car.

TROLLEY. A. Travaglili, Philadelphia, Pa., 596,131. Filed Nov. 13, 1896. Designed for double track roads having a single conductor wire.

ELECTRIC RAILWAY. W. B. Potter, Schenectady, N. Y., 596,182. Filed Nov. 18, 1896. Third rail system.

TROLLEY BASE CUSHION. W. G. Wagenhals, Dayton, O., 596,193. Filed July 23, 1897. Comprises two pairs of helical springs having spiral grooved spring bushings and a trolley base mounted on and above the springs.

RAIL-BOND. F. H. Daniels, Worcester, Mass., 596,202. Filed July 26, 1897. Comprises a rod, each end of which is reduced and provided with a tubular terminal.

TROLLEY RAIL. W. A. P. Willard, Jr., Hull, Mass., 596,224. Filed Feb. 12, 1897. Third rail, comprising a conductor, a truck normally insulated therefrom and capable of a limited longitudinal movement into electric contact therewith and a contact-rail supported upon the truck and brought into circuit with the conductor.

TROLLEY RAIL FOR ELECTRIC ROADS. W. A. P. Willard, Jr., Hull, Mass., 596,225. Filed March 5, 1897. Similar to above.

TAKE-UP FOR CONTROLLING SLACK OR TROLLEY ROPES. H. E. Adt, New Haven, Conn., 596,439. Filed May 10, 1897. Details of construction.

TROLLEY FOR ELECTRIC RAILWAY CARS. E. Cone, Chicago, Ill., 596,456. Filed Dec. 11, 1896. Employs V-shaped guards at each side of the trolley wheel and means for holding one of the wings of the guards in substantially vertical position, above the surface of the trolley wheel.

Regulation:—

PHASE REGULATOR. C. P. Steinmetz, Lynn, and W. Rice, Swampscott, Mass., 595,186. Filed Sept. 9, 1893. An electrodynamic phase controller having inducing and induced members, means for increasing the self-induction of the induced member, and a source of power driving the controller above its normal speed.

Switches, Cut-Outs, Rheostats, Etc.:—

ELECTRICAL PROTECTIVE APPLIANCE. A. S. Williams, Newton, Mass., 596,197. Filed August 26, 1897. Designed for electromagnetic apparatus.

REMOVABLE FUSE HOLDER. J. T. Hunt, New York, 596,209. Filed July 12, 1897. Details of construction.

QUICK BREAK SWITCH. R. C. Demary, Buffalo, N. Y., 596,363. Filed Aug. 2, 1897. Details of construction.

COMBINED MANUAL AND AUTOMATIC SWITCH. R. L. Hailey, New York, 596,457. Filed Sept. 27, 1897. Details of construction.

Telegraphs:—

PRINTING TELEGRAPH. B. A. Brooks, Brooklyn, N. Y., 596,320. Filed August 11, 1894. Details of construction.

Telephones:—

TELEPHONING FROM CARS IN MOTION. H. W. Libbey, Boston, Mass., 596,276. Filed April 6, 1897. Embodies two electric rails carried by springs secured to the web of the rail, a wheel having rings of conducting material in or on its flange, trolleys running upon the rings in combination with a telephone and connections between the telephone and trolley.

CAXTON POWER BUILDING is a new enterprise for Cleveland, O. It will be equipped throughout with electricity and Mr. Wilson M. Day, of the Cleveland Printing and Publishing Co., is one of the active spirits in the enterprise.

SOCIETY & CLUB NOTES

NORTHWESTERN ELECTRICAL ASSOCIATION meets on January 19 and following days at the Hotel Pfister, Milwaukee, Wis.

THE STOCK MARKET

Year Opening Well.

The corner of the old year had barely been turned before the prices of bonds and stocks began to advance briskly, and at the present writing there is a marked display of confidence throughout the entire field of American investment. Railroad earnings are good, bank clearings again show gains, there is growing activity in almost every line of trade and industry, and business failures are both fewer and smaller, as compared with the years of distress. A remarkable feature of trade is the continued large demand for goods to export, each week seeming to find some new article that can be pushed with advantage abroad. In the engineering fields of work, there is notable activity and inquiry; while the big demand for iron and steel shows that construction of all kinds is going on or contemplated, upon the largest scale.

During the past week 58,252 shares of Western Union were sold up to 93⅛. On sales of 23,668 shares General Electric rose to 36⅝; while in Boston, American Bell Telephone stood around 265 on sales of 540 shares. There were rumors current of a proposed closer alliance between the Western Union and Postal Telegraph interests. There was considerable stir in Manhattan Elevated due to reports of a coming change to electricity.

TRADE NOTES & NOVELTIES

Magnolia Anti Friction Metal and Its Imitations.

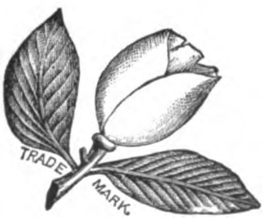
THE MAGNOLIA METAL COMPANY, whose trade extends to every part of the United States and Canada and to every civilized country in the world, have during the last two or three years had numerous suits with parties infringing their trade marks and patents. An injunction was granted on December 15, last, by Lord Chief Justice Russell in the Queen's Bench Division of the High Court of Justice, London, England, enjoining the Tandem Smelting Syndicate, Ltd., and restraining them from passing off their metal for Magnolia metal, it being made up so as to counterfeit Magnolia metal.

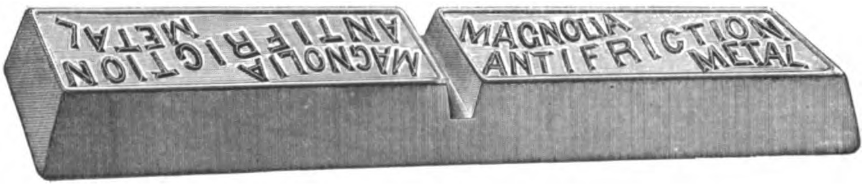
A few months ago the Globe Engineering Company, Ltd., of Manchester (now in liquidation), shipped a quantity of metal to a firm in South Africa that had ordered Magnolia metal. The metal sent to fill this order was made up into ingots as near as possible to represent the well known ingots of Magnolia anti-friction metal. They bore the words "Magnolia Anti-Friction Metal," but the trade mark, the magnolia flower, and the words "patented June 3, 1890" were not imprinted upon them. The purchaser brought an action in the High Court of Justice, at the Manchester Assizes, against the sellers, and judgment was given in his favor by the arbitrator to whom the matter was referred.

The Magnolia Metal Company has called our attention to the above and desires to warn the public against fraudulent imitations.

Genuine Magnolia anti-friction metal is made up into bars of which the accompanying engraving is a facsimile, and the trade mark, a magnolia flower, and name are always stamped on bars and boxes; and besides this the words "Patented June 3, 1890," and "Manufactured in U. S." are stamped on the under side of each bar.

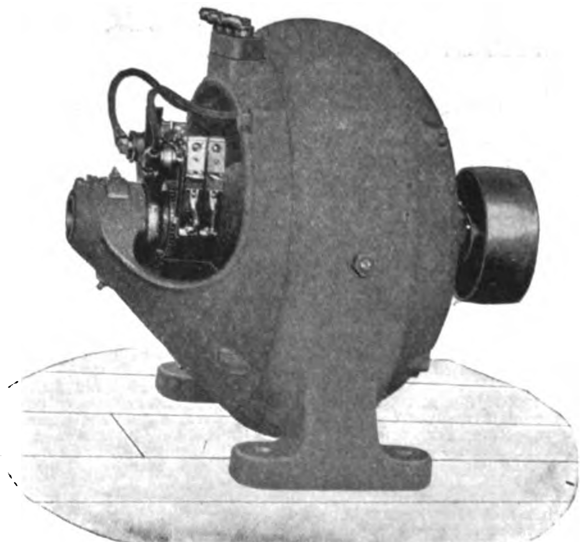
The Magnolia Metal Company, of 266 West street, New York, advise us that similar frauds are being committed in this country at this time, and they offer one thousand dollars reward to any party causing the arrest and conviction of any individual or firm infringing their trademarks or patents.





New General Electric Ironclad Bipolar Machines.

THE smaller sizes of the slow and moderate speed generators now being built by the General Electric Company, are of the bipolar type and while embodying the same style of construction as the four pole machines, differ greatly in appearance. They are known as I. B. (iron-clad bipolar) machines, and, as will be seen, have a field frame completely surrounding, and protecting from mechanical injury, both field spools and armature.



NEW G. E. IRONCLAD BIPOLAR MACHINE.

The small size of these generators, their compactness, and the small floor space occupied render them peculiarly suitable for small isolated plants, and being adapted for direct driving they make neat sets for small yacht and launch plants. The slow speed I. B. generators range in capacity from ¾ k. w. to 4½ k. w., the moderate speed from 1½ k. w. to 7½ k. w. All are wound for 125, 250, and 500 volts.

THE GENERAL ELECTRIC COMPANY desire to advise all holders of their complete Incandescent Lamp Catalogue No. 1012, of an error in the appendix, in the table on page 58. The figures .662 in the column "Life Factors" should be .562. They kindly request that all holders of the catalogue make this correction.

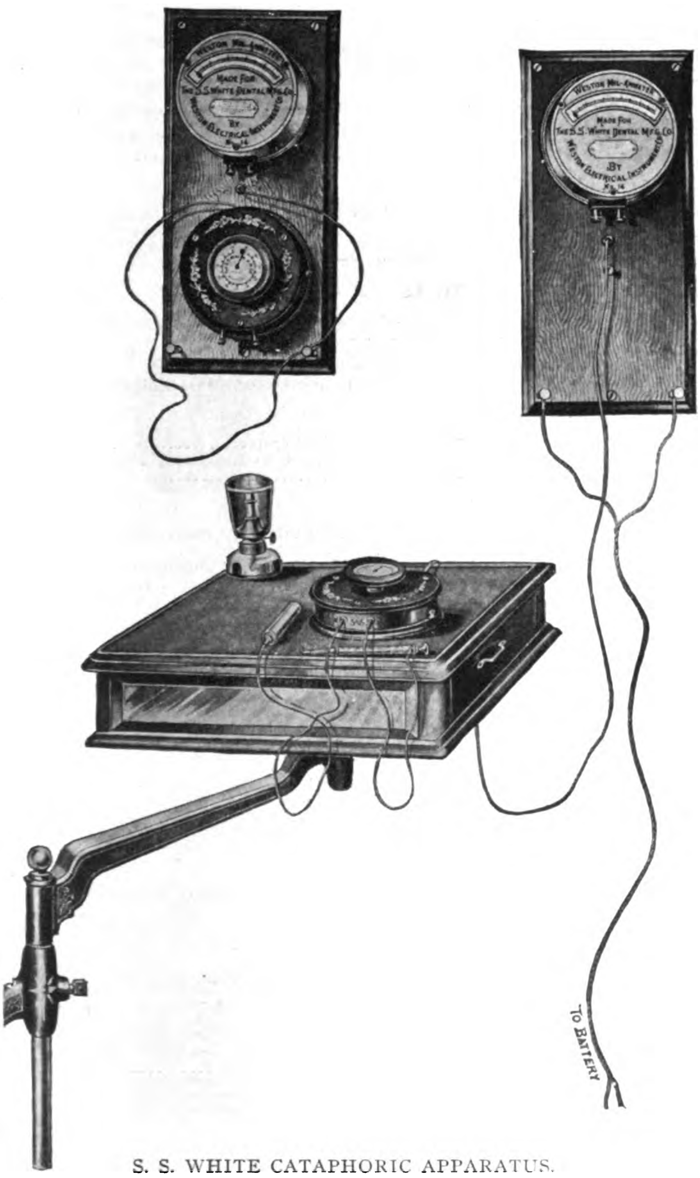
The S. S. White Dental Cataphoric Apparatus.

CATAPHORESIS as applied to dentistry has come to stay, and now no dentist can consider himself fully equipped for his work without a proper cataphoric outfit. Always abreast of the times, the S. S. White Dental Manufacturing Company has, after long experimentation, brought out a line of dental cataphoric apparatus which they have, by actual use, proved to be fully adequate to the purpose for which it was designed.

This apparatus consists of a battery, a current controller, cataphoric electrodes and a current measuring instrument.

The battery employed is a set of 18 or 24 dry cells, mounted in a neat varnished oak box. Dry cells have been selected on account of their cleanliness, and also for the reason that the amount of current required in cataphoresis is so small that a set of cells will last for one or two years even with the largest office practice.

One of the outfits is shown in the accompanying engraving,



S. S. WHITE CATAPHORIC APPARATUS.

the current controller or regulating rheostat being shown resting on the bracket table. This rheostat is, in a measure, the most important part of the outfit as the current must be applied to the patient by very small increments. In the present instance graphite has been selected as the resistance material, and prolonged tests by the S. S. White Company have demonstrated the permanence of the action of this type of rheostat.

The controller, shown on the bracket table, consists of a polished wood cylindrical case with black enameled slate top 5½ inches in diameter and 1½ inches high. The regulating wheel is raised 1 inch above this. Four cone socket connecting posts receive the cords from the battery and electrodes, and a switch on the side of the case cuts off the entire current. This latter is small and neat, and supersedes the separate switch previously used on the battery cord.

The regulating wheel is 2⅜ inches in diameter, and contains the scale protected by a crystal cover. The scale is graduated into 100 equal parts, which permits the conditions of an experiment to be exactly repeated, but does not give any electrical data. When desired, the scale is graduated to read the volts on the patient's circuit, and by a new method this holds good independently of the number of cells in circuit. Following the most approved practice the shunt method of connecting up the resistance has been adopted.

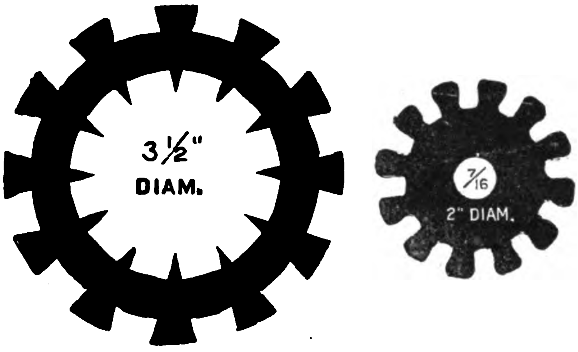
For measuring the current the Weston milliammeters have been adopted, which are specially made for the purpose.

The meters, one of which is shown hung up in the engraving, are about 5½ inches in diameter and 2⅞ inches high. They read five milliamperes divided to twentieths of a milliampere, and their movement is so delicate that an increase or decrease of one-hundredth of a milliampere can be detected. The outfit also comprises the necessary electrodes.

With the apparatus described, the dentist is in a position to treat his patient intelligently with the absolute knowledge, at every instant, of the condition of the treatment.

Mianus Armature Discs.

MANY who make dynamos and motors do not care to get out dies for making armature punchings. The Mianus Electric Company, of Mianus, Conn., make several sizes and carry them in stock, especially the small sizes of toothed



MIANUS PUNCHED ARMATURE DISCS.

punchings such as 1¾, 2, 3, 3½ and 4 inches. They also make larger sizes to order, both plain and toothed, from special soft iron rolled for the purpose. Our illustration shows two of the styles of discs furnished by the company.

The Cherry Electrical Instruments.

TWO valuable but inexpensive testing instruments for both students and practical electricians are now being manufactured and sold by the Cherry Electric Works, 25 and 27 Third avenue, New York, at the price of $1.50 each. These instruments are a voltmeter reading from 0 to 10 volts, and an ammeter reading from 0 to 10 amperes. They are not toys because sold at a low price, but are scientifically constructed instruments. For amateurs and others experimenting with batteries, dynamos, motors, or using current for any purpose and for whom the standard instruments are too expensive, these will be found to be just what is wanted. After the first of January these instruments will be constructed in hardwood cases which give them a very handsome appearance.

THE U. S. ELECTRICAL SUPPLY CO. have now moved from 120 Liberty street, to their new offices and factory in the Lexington Building, at 25th street and Lexington avenue, where they will manufacture apparatus for wireless telegraphy, X-ray apparatus, and Clarke's new combined stereopticon and vitascope, which is a model of compactness and operates without any of the noise which has been one of the principal objections to such apparatus in general.

ADVERTISERS' HINTS

THE PRATT & WHITNEY COMPANY, Hartford, Conn., advertise vertical and horizontal adjustable multispindle drilling machines.

THE CHERRY ELECTRIC WORKS, 25 Third avenue, New York, offer direct reading ammeters or voltmeters reading from 0 to 10 at $1.50, and reading from 0 to 25 at $5.00 each.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, New York, have something to say on the way the dollars get away and how it may be prevented.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, will send a sample two ounce box of the "Highland" soldering paste on receipt of twenty-five cents.

THE NON-POLARIZING DRY BATTERY COMPANY, 625 Broadway, New York, claim their "O. K." cell to be more efficient than the old fluid style, and cleaner, more compact and better in every way.

THE MONTAUK MULTIPHASE CABLE COMPANY, 100 Broadway, New York, advertise a new and marvellous electric cable for interior use which is said to be both fire and burglar proof.

THE SHAWMUT FUSE WIRE COMPANY, 93 Federal street, Boston, Mass., illustrate their style of fuse designed to fit the present 500 volt fuse-blocks.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., advertise circuit breakers.

TOWNSEND & DECKER, attorneys at law, 5 Beekman street, New York, may be consulted on all matters pertaining to U. S. and foreign patents.

THE ADAMS-BAGNALL ELECTRIC COMPANY, Cleveland, Ohio, have introduced a hanger-board complying with the requirements of the National Board of Fire Underwriters.

THE C & C ELECTRIC COMPANY, 143 Liberty street, New York, advertise all classes of dynamos and motors for lighting and power.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa., have sold the Western Union Telegraph Company 436 chloride accumulators, which it will install in its Memphis office, displacing 5,250 gravity cells.

NEW YORK NOTES.

THE GENERAL ELECTRIC COMPANY will be represented at the Northwest Electrical Association Convention at Milwaukee, by the following gentlemen from its Chicago office: Messrs. J. Scribner, R. A. Swain, P. A. Clisdell, F. N. Boyer, and Thomas Ferris, of Milwaukee. It will make an exhibit as usual at these conventions, which will consist of a full selection of wiring supplies, recording wattmeters, inclined coil instruments, new transformers, and long burning arc lamps for direct current, alternating current, railway and power circuits. Its headquarters will be in a special room at the Pfister Hotel, close to the Club Room where the meetings of the association will be held.

P. M. MOWREY & COMPANY, 318 Broadway, New York, have just issued a very neat and pretty little pamphlet devoted to their work in the Bowling Green Building, and supplemented by a long list of their public and private installations. They have a large staff, including Mr. E. H. Curtis, electrical engineer, and have a good deal of work ahead in 1898.

PHILADELPHIA NOTES

MESSRS. VALLEE BROS. & COMPANY, through their agent, Mr. D. B. Scarborough, have sold 40,000 feet of Armorite interior conduit to Wilkesbarre, Pa., parties to be used in the new Hotel Sterling now under construction there.

THE PENNSYLVANIA ELECTRIC COMPANY, of Marietta, Pa., are the happy recipients of an order for 500 telephones, complete, from one company, besides several smaller orders.

MESSRS. JOHN E. GRAYBILL & COMPANY, of York, Pa., who for several years have conducted a successful electrical supply and construction business, have recently added a well equipped machine shop, where they will manufacture switches and switchboards, rewind armatures, and do special machine work.

MR. ALFRED F. MOORE, Philadelphia, has issued for 1898 one of his handsome conspicuous calendars, with large figures which he who runs may read. It is a good thing for the office or factory.

G. F. BRUNT PORCELAIN WORKS, of East Liverpool, O., have issued one of the daintiest, prettiest sheet calendars of the season and one which will serve all through the year to keep in mind their porcelain for electrical purposes.

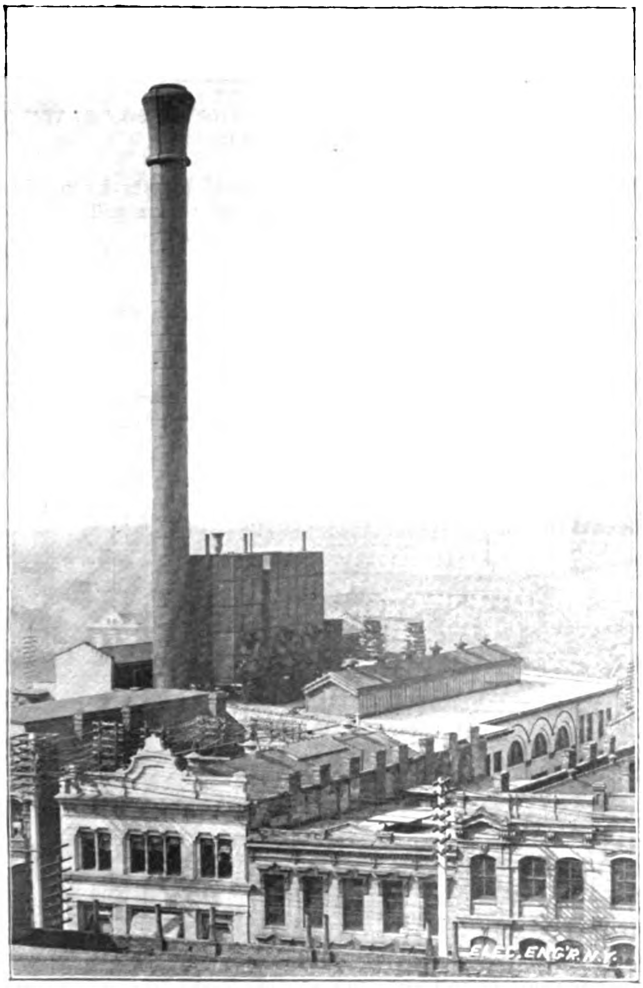
Vol. XXV. JANUARY 20, 1898. No. 507.

ELECTRIC LIGHTING

The New Station of the Edison Electric Co., of New Orleans, La.

WHILE one hears of constantly increasing indust·ial activity in the South and the introduction of electric light and power in particular, it must not be supposed that electrical work is of recent advent in that section of the country. On the contrary, some of our Southern cities were among the earliest to take up the electric light, and among them was New Orleans, where a company was organized as far back as August, 1886, under the name of the Edison Electric Illuminating Co. The work of the company progressed during each succeeding year, and in 1893 a reorganization was effected, in



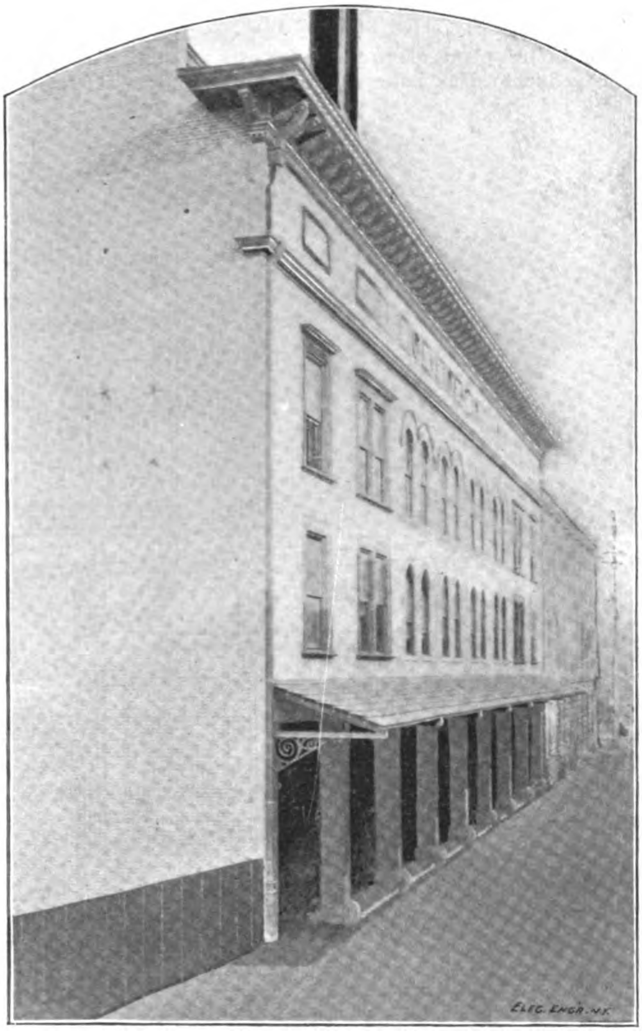
BIRD'S-EYE VIEW OF NEW STATION OF NEW ORLEANS EDISON CO.
(The view shows roof of office and station, with smoke stack and cooling towers.)

order to broaden its powers, when the present name was adopted.

The original equipment of the company naturally contained the best the art afforded at the period, but with the ever-increasing demand it became obvious some time ago, that greater economy could be effected by abandoning completely the old station apparatus and installing a modern plant throughout. The funds having been authorized for this purpose, work was begun on the new station during the early part of last year, and now the new station has begun its work with every prospect of meeting the high expectations of its projectors. The present article illustrates and describes its leading features.

THE STATION BUILDING.

The new station building is erected on a lot 138 feet long by 100 feet in depth. Owing to the nature of the soil the ground had to be piled, 933 50-foot piles being required to sustain the weight of the building and contents. After the piles had been sawed off level, 12x12 yellow pine stringers were laid on top, securely fastened to the piles by means of drift bolts.



FRONT OF THE NEW STATION OF THE NEW ORLEANS EDISON CO.

All the loose earth was then removed from around the top of the piles, and the spaces thoroughly filled in around with concrete flush to the top of the stringers. On top of the stringers and running at right angles to each other, 4x12 pecky cypress planks were laid, covering the entire area of the foundation. On the top of this timber grillage a bed of concrete three feet deep was laid. The engraving on page 74 shows the method of construction adopted.

It was found on driving the piles that at a depth of about 45 feet they met with great resistance, which on investigation was found to be a shell bank, thus insuring a perfect rest for the piles. The weight carried by each pile, including the building, coal and machinery, was calculated to be 13½ tons.

The building proper is a steel structure, the brick walls simply acting as a curtain to keep out the weather. The engraving, page 74, gives a good idea of the steel structure and

shows the coal bunkers in the boiler room and the electric crane in the engine room. The coal bunkers are carried from the roof trusses over the boiler room, and by them the load is transmitted to the steel columns of the building. The bunkers are built to carry 1,000 tons of coal. All the columns, which are of the Z-bar type, after being erected, were filled with cement mortar, one part cement and two parts sand. This has the effect of deadening the noise usually made by traveling cranes where the columns are left hollow, and helps to stiffen the columns.

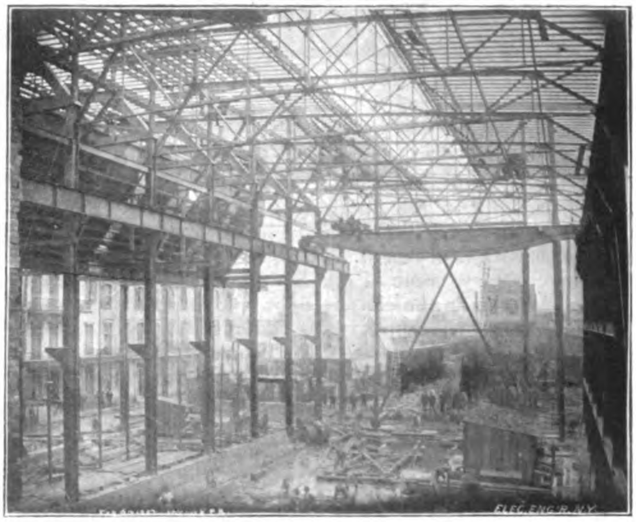
The steel work was built and erected by the Berlin Iron Bridge Company, of East Berlin, Conn. The piling and masonry work was done by James Stewart & Co., of St. Louis. The exterior of the building is finished with St. Louis pressed brick of a buff color, with terra cotta trimmings. The interior of the engine room is faced with white enamel brick for a height of 12 feet, above which it is faced with St. Louis pressed brick.

THE BOILER PLANT.

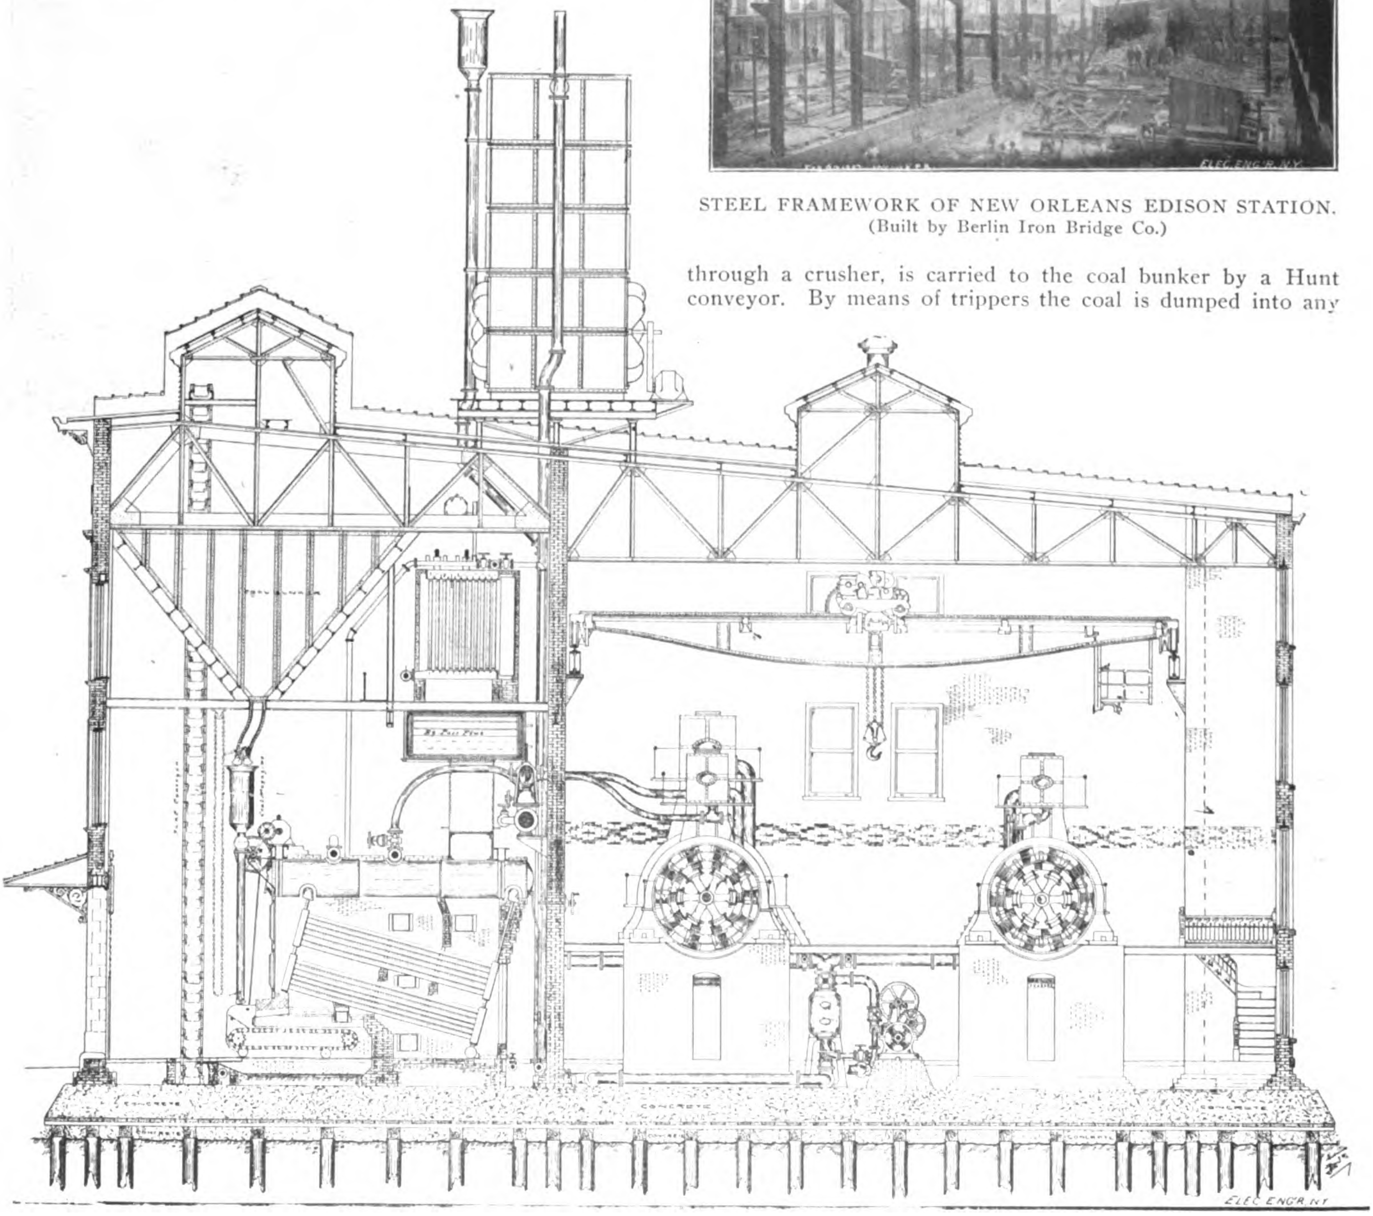
The boiler plant at present consists of four Babcock & Wilcox double deck boilers, set in two batteries. The boilers have forged steel headers, and are built for a working pressure of 180 pounds. Each boiler is equipped with a Babcock & Wilcox chain grate stoker, having 69 square feet of grate. The boilers have a total heating surface of 16,724 square feet. The normal rating of each boiler is 500 h. p., but will develop a maximum of 750 h. p. The boilers have brick settings, the facing being white enamel brick, which enables them to be kept perfectly clean, besides making a very pretty setting.

COAL HANDLING MACHINERY, ECONOMIZERS, ETC.

The coal, which will be Alabama run of mine, after passing through a crusher, is carried to the coal bunker by a Hunt conveyor. By means of trippers the coal is dumped into any one of the five pockets of the coal bunker. From these pockets the coal is dropped in a magazine, as shown above, where an accurate weight of coal consumed by each boiler is kept. From the magazine the coal is fed into the stokers as



STEEL FRAMEWORK OF NEW ORLEANS EDISON STATION.
(Built by Berlin Iron Bridge Co.)

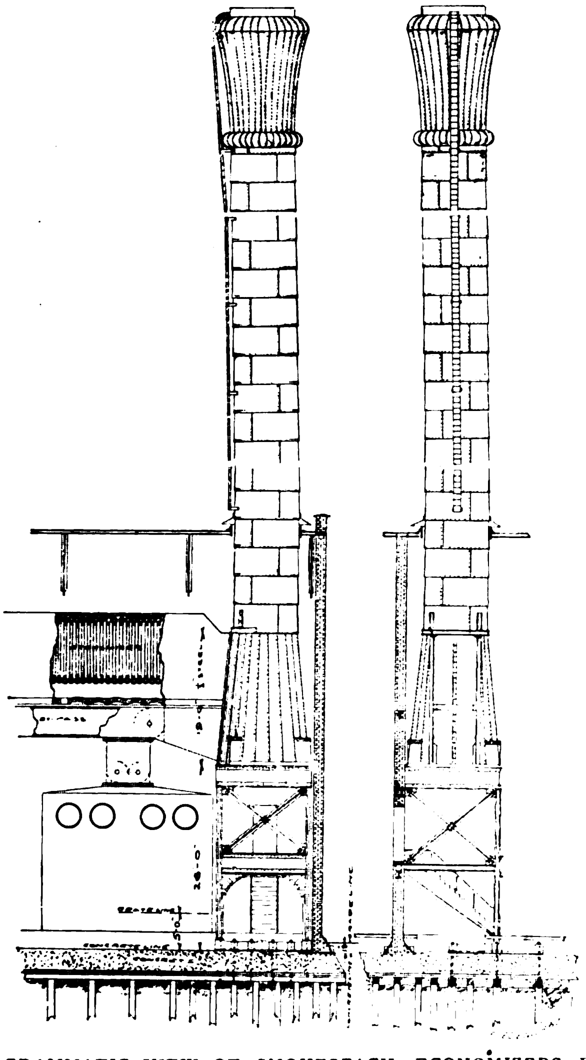


ELEVATION OF NEW ORLEANS STATION.
(Showing Engine and Dynamo Room, Boiler Room, Economizers, Condensers, Pumps, Cooling Tower, Etc.)

required. By this process there is absolutely no handling of coal except by machinery. The stokers, coal crusher and conveyor are driven independently by G. E. 1,000 motors.

Green economizers are located above the boilers, as shown in the sectional elevation opposite, and are arranged with by-pass so that they can bé cut out for cleaning or repair. They have a capacity of 2,000 h. p., and contain 8,640 square feet of heating surface. They are encased in a sectional sheet iron casing, lined with four inches of abestos instead of the usual brick setting. The iron casing was adopted for lightness and on account of accessibility and to reduce the cost of repairs. The economizer scrapers are operated by a G. E. 1,000 motor. The dampers are controlled by a Locke damper regulator.

The smoke stack, which is 200 feet high above the grate bars, is built of steel, lined with fire brick for a distance of 80



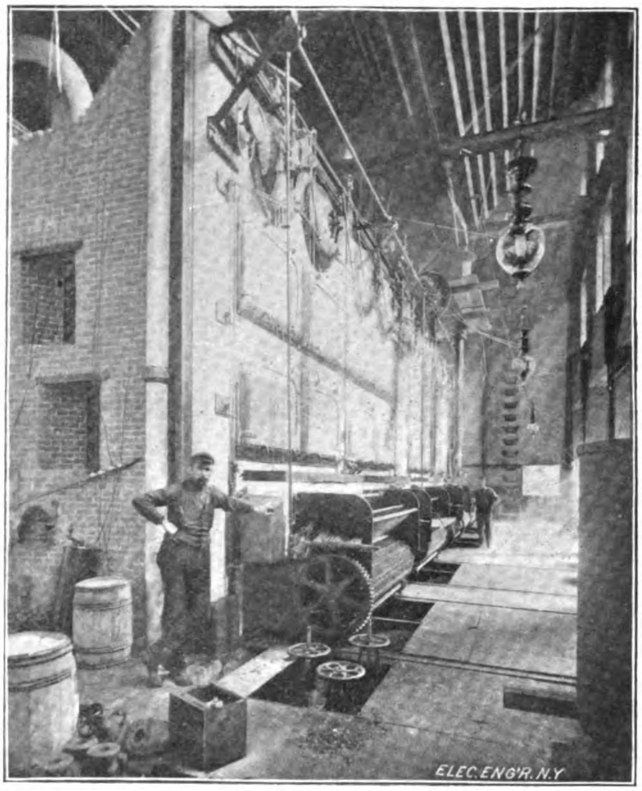
DIAGRAMMATIC VIEW OF SMOKESTACK, ECONOMIZERS, ETC.
(The stack is shown shortened.)

feet above the base. The stack is carried on a sub-foundation built of columns and securely braced, as shown on this page. Two of the columns in the center wall of the building carry half the weight of the stack, and the two other columns that carry the remaining half are fastened securely to the piling, provision being made for this when the piling foundations were put in. The stack is self-supporting and designed to withstand a wind pressure of 100 miles an hour.

The oil room is located in the boiler room, and the oil flows by gravity to the engines and pumps. The waste oil is collected in a tank in the basement and pumped back to the oil room, where it is filtered through a Turner filter. In the oil room are also located two Edminston filters for extracting the oil from the water from the hot well before entering the boilers. There is also a compressed air system for cleaning the generators, etc., an air pressure of 20 pounds being carried in the receiver, from which small pipes are led to the generators where a hose connection is made to clean the different parts of the machines. The air compressor is driven by a motor directly connected to the crank shaft.

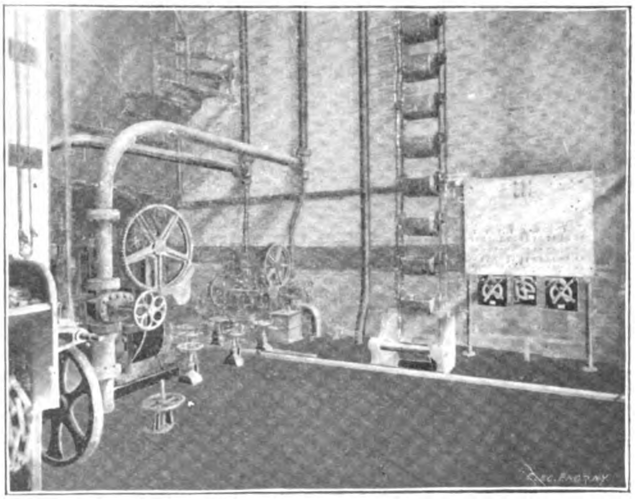
STEAM PIPING.

The steam piping, as will be seen from the plan, page 76, has been reduced to a minimum. The main header, which is built



BABCOCK & WILCOX BOILER PLANT, NEW ORLEANS EDISON STATION.

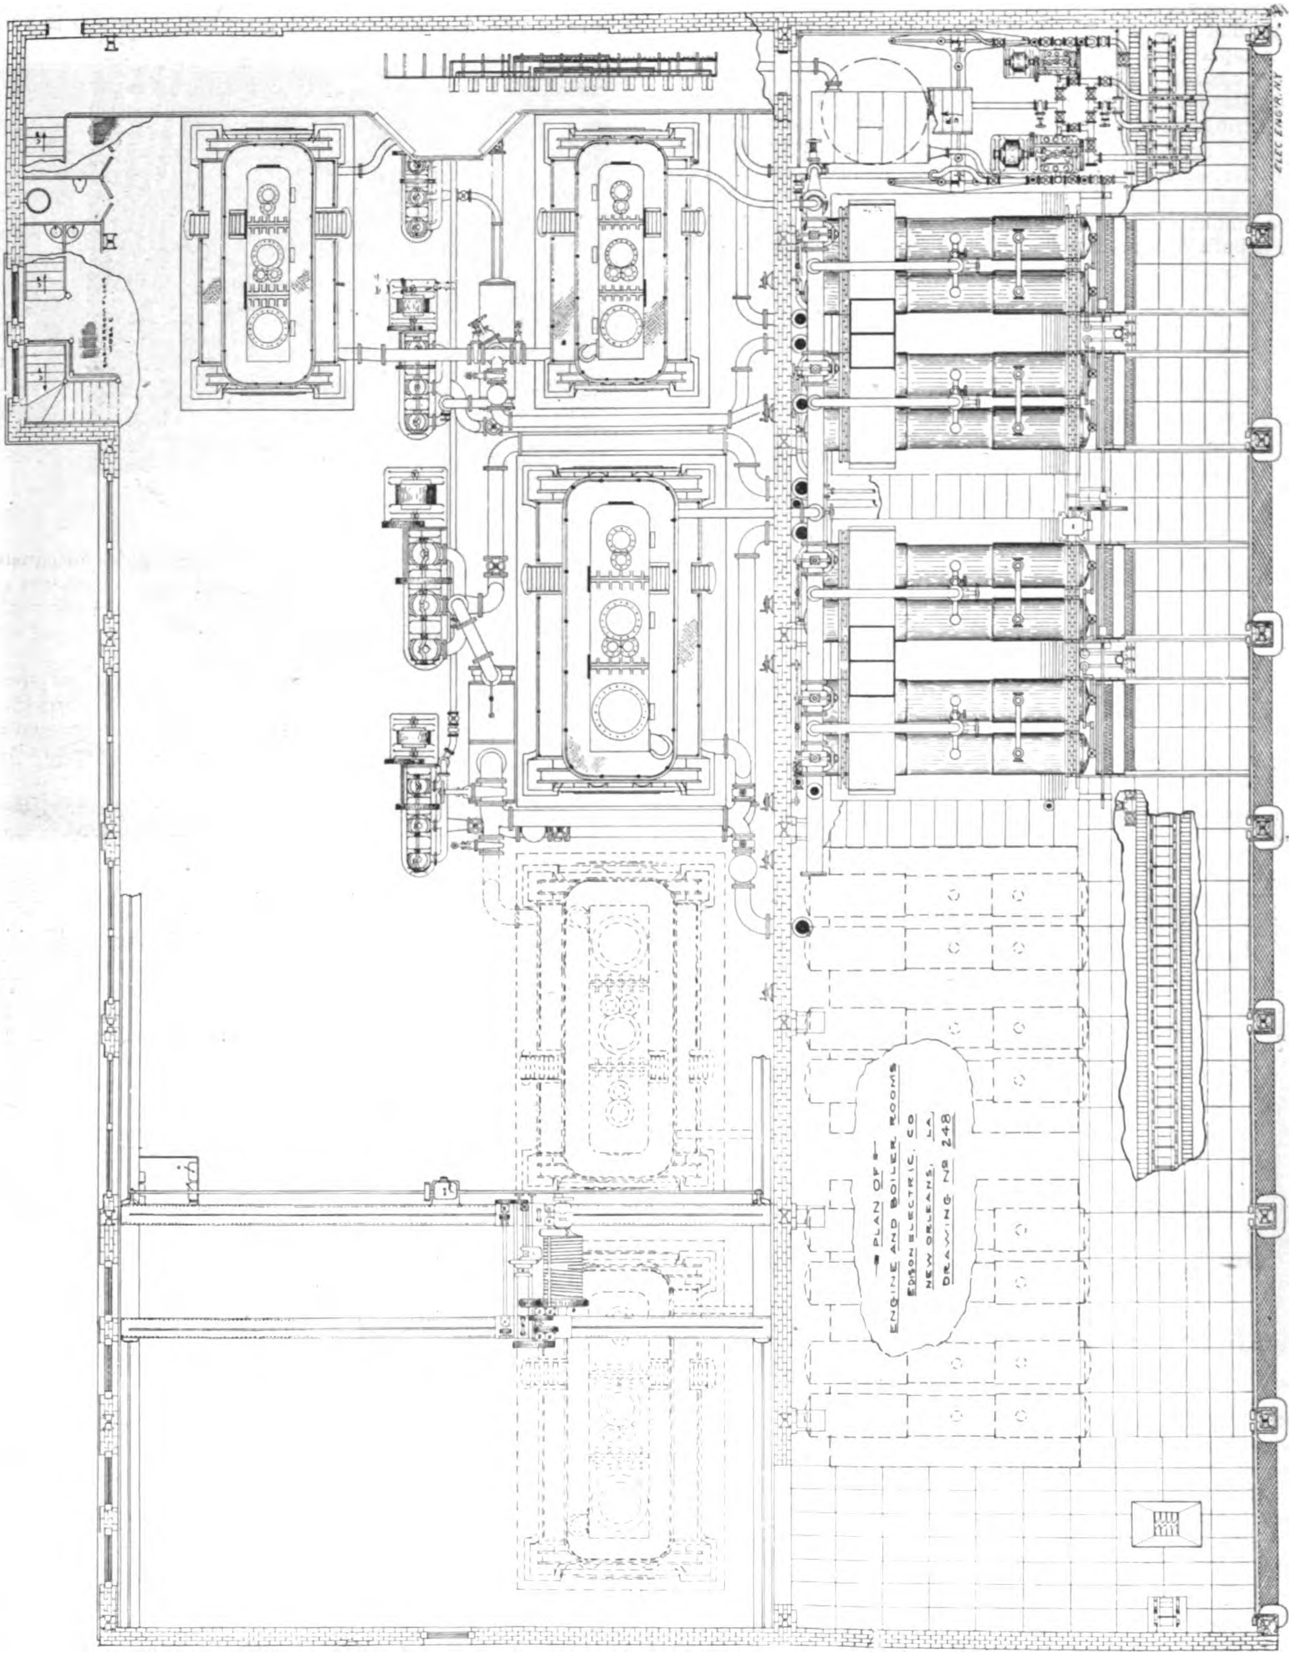
of cast steel, was made by the Penn Steel Casting & Machine Co. The use of cast steel does away with a number of joints and threads and makes a very compact and solid piece of work. The header is carried on brackets attached to the columns of the building, and rests on expansion rollers, which give ample room for expansion and contraction. The header is securely fastened in the center so that the expansion is reduced to a



CORNER OF BOILER ROOM, EDISON STATION, SHOWING PUMPS, ETC.

minimum. The connections from the boilers to the header, and from the header to the engines are copper bends, which allow of expansion and contraction. These bends and the header comprise all the live steam pipes. In the remainder of the

piping (exhaust and water) steel pipe is used with flanges peaned on. The flanges are made from steel forging, and after they are put on, the pipes are faced up so as to be true. The gaskets used throughout the entire system are corrugated



PLAN OF ENGINE AND BOILER ROOMS, NEW STATION OF NEW ORLEANS EDISON CO.

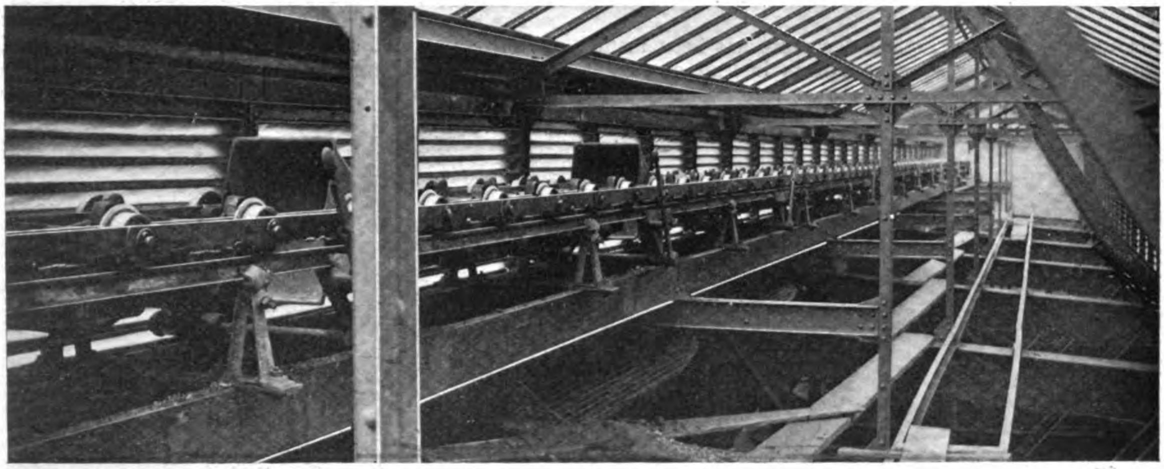
copper. The Shook, Anderson Mfg. Co., of Pittsburg, furnished and installed the piping.

THE ENGINES.

The engines, of which at the present time three are being installed, two 600 h. p. and one 1,200 h. p., are of the Williams triple expansion marine type with receivers, cylinders side by side, each acting on a separate crank with direct connected generators on either end.

The 600 h. p. engine has cylinders 14½" high pressure, 23" immediate pressure, and 37½" low pressure, by 28" stroke; speed, 150 revolutions per minute. The 1,200 h. p. has cylinders 21½" high pressure, 35" intermediate pressure, and 55½" low pressure, by 36" stroke; speed, 120 revolutions per minute. These engines give their rated power at about 25 pounds m. e. p., and are to operate condensing under 175 pounds pressure at the throttle.

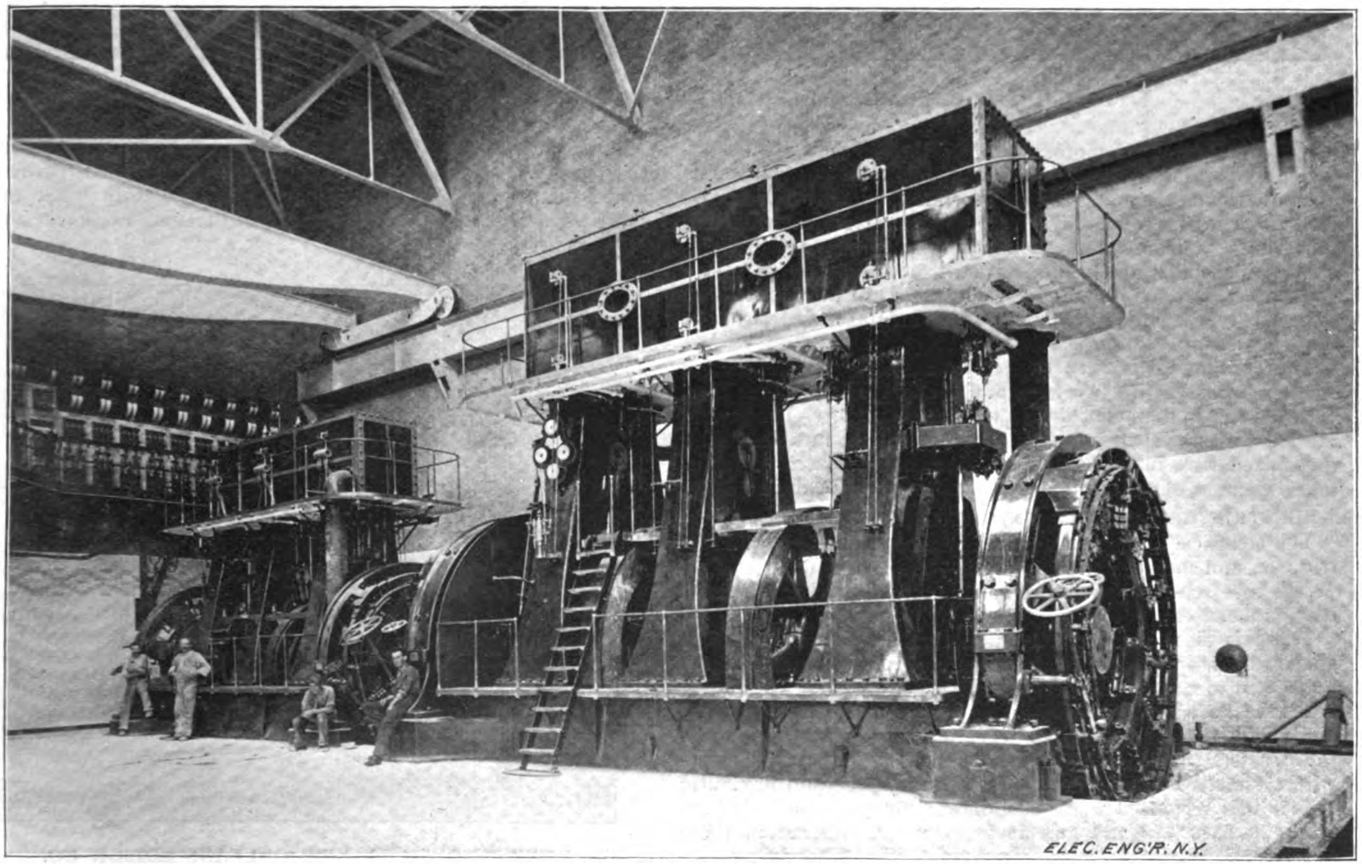
The shafts are larger than marine sizes and are provided with heavy flywheels between cranks, and are extended out each end to carry the armature. The weight of the armature and flywheel, being approximately the same, gives an even distribution of weight upon the several bearings, and the extreme rigidity of the shaft secures perfect alignment and freedom from undue straining.



HUNT COAL CONVEYOR SYSTEM, NEW ORLEANS EDISON STATION.

The valve system differs considerably from the usual marine practice. Piston valves with self-adjusting relieved packing rings are used for the high pressure cylinders. The same valves are used also in intermediate cylinders, and flat multiported valves are used for the low pressure cylinders, having separate steam and exhaust valves, driven by two eccentrics, one for steam and one for exhaust. Intermediate quarter-crank rockers are used on both low pressure valve gears also, in order to secure a wide opening with short traveling of valve. Double piston valves are used on the intermediate pressure cylinders, also on the high pressure cylinders, so as to secure small cylinder clearance with light weight of valve. Unusually large and free openings are provided for steam everywhere, and a very high mean effective pressure is maintained for any given number of expansions and consequent terminal pressures, thus insuring one of the main elements of economy in the use of steam in the steam engine. The throttle valve is of the flanged lever type and operated from the starting platform.

All cylinder cocks and their drains and by-passes are operated from the steam platform. The cylinders are provided with spring relief valves at the top and bottom, as a protection against water hammer. The receivers and the cylinders are protected with a non-conducting covering, over which there is a steel jacket held in place by bands. Steel jackets are provided for all cylinder heads, and reheating coils are placed in the receivers. These reheating coils are composed of 1¼ inch



VIEW IN ENGINE AND DYNAMO ROOM, NEW STATION OF NEW ORLEANS EDISON CO.

copper pipe. A boiler pressure of 170 pounds is admitted to all jackets and both reheaters. The general design of the engine, as will be seen on the page opposite, is massive, there being abundant strength and surface provided everywhere. The railings and posts are polished, as also are all connecting rods and all reciprocating parts.

PUMPS.

In the matter of pumps, a radical departure has been made, all pumps being driven by electric motors instead of steam. In the present installation there are two feed water pumps driven by slow speed motors, and different speeds can be obtained by varying the pressure from 230 volts to 115 volts. The air and circulating pumps are independent and are driven and controlled in the same way. The Wheeler Condenser & Engineering Co. installed the condensers and pumps, which include the installation of the Barnard cooling towers. Two condensers, of 1,200 h. p. and 2,400 h. p., are of the well known Wheeler type, while the pumps are manufactured by the Knowles Pump Works.

The cooling towers are 14 feet square by 30 feet high, the smaller tower having two fans, and the larger tower four fans, each ten feet in diameter, driven by electric motors. The towers are fed with a system of water distribution and furnished with galvanized wire mats, having sufficient cooling area to maintain a vacuum of 25 inches in the exhaust main of the engines.

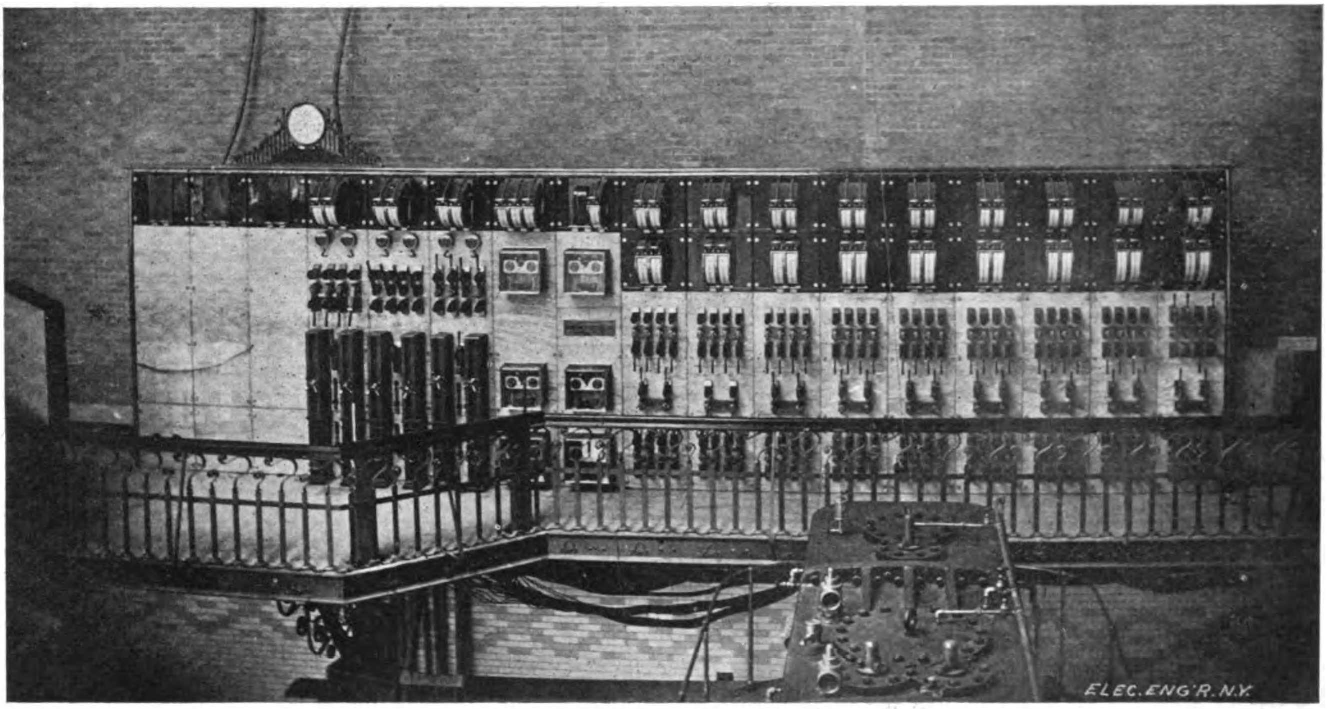
ELECTRIC GENERATORS AND AUXILIARY APPARATUS.

The electrical apparatus was furnished by the General Electric Co., and includes two M. P. 12— 400-120 generators, four M. P. 10— 200-150 generators and motors for driving pumps, fans, stokers, etc.

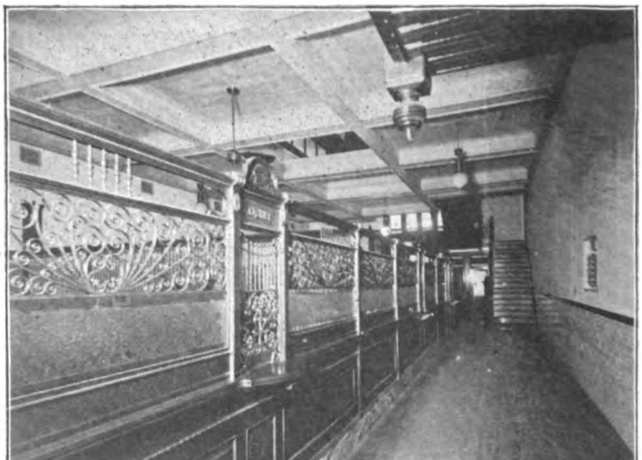
There is also installed a combination set consisting of a standard low frequency 150 k. w. monocyclic generator direct connected to a 250 volt multipolar ironclad motor. The motor will take its current from the station bus-bars, and the alternator will be used to supply alternating current for lighting in the districts which are beyond the reach of the present three-wire system. The considerations of floor space and flexibility render this set exceedingly economical for the conditions existing at New Orleans, and as a further consideration, there is a possibility that at some future time, when alternating current direct driven generators are installed, the set above referred to can be placed in some outlying part of the city and operated backwards; that is, with the alternator as a synchronous motor, to supply current to feed into the outside wires of the three-wire system.

In addition to the motor driven alternating generator a steam driven set of 300 k. w. is being installed, composed of a compound condensing Williams engine of the same type as those already described, and an A. M. 48-300-150 generator. This latter is chifly added to secure reliable service to the customers and used during the heavy load hours when the direct current units are loaded to their capacity.

The switchboard shown below was also built by the General Electric Co., and is made of blue Vermont marble highly polished. There are three bus-bars on it, so that three different pressures can be delivered from the board at one time. All switches are arranged so that when they are thrown up the pressure is increased on the feeders, and when thrown down the pressure is lowered, and the regulators work the same way. The instruments used are of the Van Vleck-Weston edgewise type.



SWITCHBOARD GALLERY, NEW ORLEANS EDISON STATION.



VIEW IN OFFICES, NEW ORLEANS EDISON CO.

The output of the station is registered on Thomson recording wattmeters, of which there are six, two for each bus-bar. The switchboard is elevated 15 feet above the engine room floor, where the attendant has full view of everything that is going on, and at the same time has all the working parts of

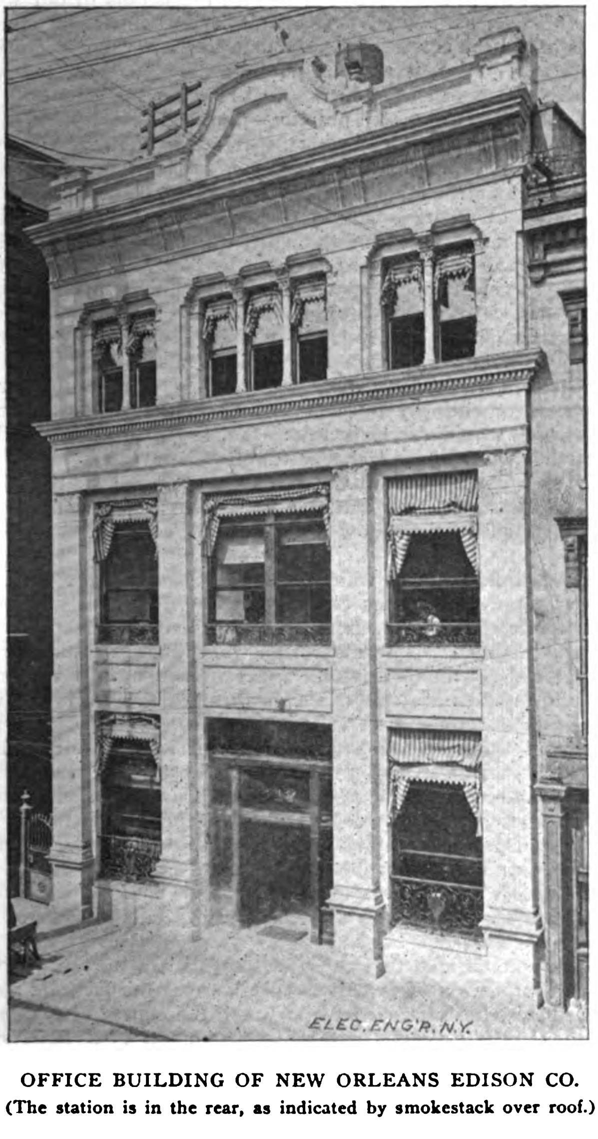
the board easily under his control, as the generator panels and testing instruments are within a radius of four feet.

While the Thomson recording wattmeters just mentioned indicate and record the production, there are means provided at every stage showing the economy in operation or the condition of the apparatus; namely, volt and amperemeters, wattmeters showing the energy consumed by the various auxiliaries, scales, water meters, showing the performance of boilers and engines, etc.

The engraving on page 79 shows the exterior of the office of the New Orleans Edison Company, which faces on another street but abuts on the station, being cut off from the latter by a fire wall, through which are openings conecting the two. The interior view of the office shows the accounting department. The meter department and daughting room are also located in the office building.

THE COMPANY'S OFFICERS.

The present officers of the company are: W. T. Hardie, president; Ed. L. Bemiss, vice-president and general manager; W. J. Kehl, secretary and treasurer. Mr. S. D. Greene, of the



OFFICE BUILDING OF NEW ORLEANS EDISON CO.

(The station is in the rear, as indicated by smokestack over roof.)

General Electric Co., is one of the directors. The building of the new station has been directly under the charge of Mr. J. B. Craven, the general superintendent of the company. Mr. Frederic Sargent acted as consulting engineer. To him and to Mr. John Kruesi and Mr. Craven is due the credit of the general design and layout of the plant. The result has been a most happy one, and the company is to be congratulated on the possession of a plant up-to-date in every respect.

Have read The Electrical Engineer for the last seven years and have always found it excellent.—W. P. M., Brooklyn, N.Y.

German Lighting Plant For Buenos Ayres.

A special cable dispatch from Berlin, of January 4, says: The German Trans-oceanic Electric Company, with headquarters here, has been formed, with a capital of 10,000,000 marks ($2,500,000), for the purpose of erecting electrical stations in America.

A central station will first be established at Buenos Ayres for lighting and general supply.

MECHANICAL

The Comparative Cost of Steam and Electric Power.—VI.

(Concluded.)

BY IRVING TAYLOR.

COMPARISONS.

In Table 7 we have gathered together the final cost results for both steam and electric power, so that they may be available for easy reference, and we have also plotted them out as curves in the accompanying diagram, so that their significance may appeal graphically to the eye.

Referring to the curves, the heavy solid lines show the cost of electric power; the light solid lines the cost of steam power with coal at $4 per ton; and the dotted lines the cost of steam power with coal at $2 per ton. It will be seen that, with the rather ideal case (case I, curves A and a) of a load factor of unity, the electric power has the advantage in cost over steam power, with coal at $4, until 25 h. p. is reached. Above this

TABLE 7—COST OF STEAM AND ELECTRIC POWER.

H. P. of Plant.	Description of Plant.	Load Factors. Ideal, Constant Load. 1.00	Variable Loads. .46	.18
		Cost of Power; Cents per B. H. P. H.		
	Electric motors	3.9	6.9	10.02
10	Engines; coal at $4	4.92	9.19	22.05
	Engines; coal at $2	4.32	8.18	20.
	Electric motors	3.58	4.06	7.98
25	Engines; coal at $4	3.47	6.1	14.28
	Engines; coal at $2	2.99	5.33	12.72
	Electric motors	3.46	3.87	4.96
50	Engines; coal at $4	2.54	4.47	10.22
	Engines; coal at $2	2.14	3.86	9.05
	Electric motors	3.41	3.79	4.87
100	Engines; coal at $4	2.14	3.41	7.56
	Engines; coal at $2	1.79	2.89	6.57

power steam is cheaper than electricity, and becomes increasingly cheaper as the load increases.

Comparing curves B and b (case II), it will be noticed that electric power has the advantage of steam power on the score of cheapness until 50 h. p. and 80 h. p., with coal at $2 and $4, respectively, are reached, after which steam power is a little cheaper. It will be remembered that this case II is what may be called the lower limit of variable load cost.

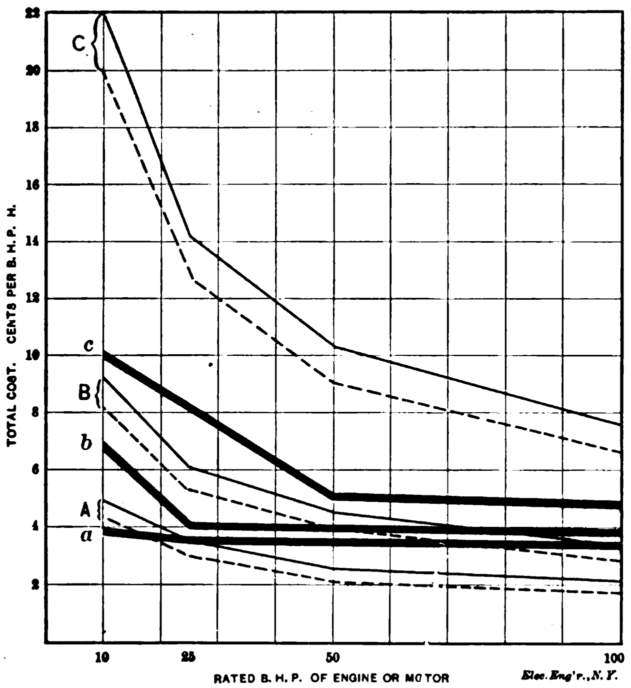
We will now consider the upper limit, which is case III. Comparing curves C and c, it will be seen at once that electricity has an enormous advantage throughout. The spaces between curves B and C for steam power, and between b and c for electric power, may be taken to include the cost of power for all cases of variable loading. A mere glance serves to show that, within the limits of power chosen, electric power, on the cost account alone, easily holds the field.

We are now in a position to view this question of the size of load factors from another standpoint, from which we may be enabled to understand why it is, even in those plants where more or less data has been obtained as to their working, that the load factors are generally thought to be much higher than they really are. This is due to the fact that the indicated h. p. is generally used as a basis of opinion and figures instead of the brake h. p. To illustrate our meaning we will take the case of the 10 h. p. engine, with a load factor of 46 per cent. in case II, and 18 per cent. in case III, and show how

much these figures are increased by calculating on the basis of indicated power instead of actual power.

It must be remembered that, as we have explained before, what we have called the "load factor" is in reality the factor of plant loading. As we wish to call attention to the actual load factor we will distinguish it by the term "actual," and the reader will understand that we designate by that term the ratio of the average indicated load to the maximum indicated load.

In table 3 B and 3 F, multiplying each of the amounts opposite "I. h. p. input" by the corresponding hours per day at that input, summing up and dividing by 10 (hours per day) we



COMPARATIVE COSTS OF STEAM AND ELECTRIC POWER UNDER VARYING CONDITIONS OF LOAD.

Steam Power.—Dotted lines, coal at $2 per ton; solid lines, coal at $4 per ton.
Curves A—Steam power, Case I.
Curve a—Electric power, Case I.
Curves B—Steam power, Case II.
Curve b—Electric power, Case II.
Curves C—Steam power, Case III.
Curve c—Electric power, Case III.
Most cases of variable load steam power will lie between curves B and C.
Most cases of variable load electric power will lie between curves b and c.

obtain the average I. h. p. of 8.9 in case II, and 6.1 in case III. Dividing each of these amounts by 14.3 (which is the maximum I. h. p. of the engine), we obtain a load factor of 62.2 per cent. in case II, and 42.7 per cent. in case III, as against 46 per cent. and 18 per cent. respectively, when the load factor was based on the brake h. p. output. If we divide the above figures, 8.9 and 6.1, by the maximum figures found opposite "I. h. p. input" in tables 3 B and 3 F, that is, by 12.3 and 8.3, respectively, we will obtain figures which are the actual load factors, based on the I. h. p. of 72.4 per cent. for case II and 73.5 per cent. for case III. Both of these actual load factors are what might seem, at a cursory glance, to be very satisfactory, the one in case III being even somewhat higher than that in case II. This is the reason why most men think their plants are operating under favorable conditions, when, as a matter of fact, if the results were reduced (as they ought to be) to actual brake h. p. they would shortly form a very different opinion.

It will be understood that these widely differing results are merely due to the constant internal frictional load of the engine, and apply with still greater force to that larger, external, frictional load—the shafting—which is only used in transmission, and may often be entirely discarded when electric motors are used. Following this line of thought, it may be said in a general way that, owing to the fact that most classes of machinery use power rather intermittently, a rather high load factor will oftentimes only indicate that there is a large constant loss of power in the transmitting devices; so that, on the very field in which electricity is at somewhat of a disadvantage on the cost score as compared with steam, it is often possible, by its use, to entirely overcome that disadvantage by cutting down the wasteful transmitting machinery. In fact electricians generally count on this fact, and it is an every-day occurrence to see a steam engine replaced by several motors with a much smaller total power.

On the other hand, if the load factor is very low, it generally indicates that there is not a large constant load of any kind, and that the chances of reducing the power actually delivered are rather slim. It will be noticed by reference to the curves, however, that, in this field steam power cannot compete with electric under any circumstances.

We must ask the reader to give our statements some breadth, as we have not ourselves done so, but have made them as precise as possible, so that, in proportion as they are valuable, they may make an impression which shall be definite. Nor have we gone deeply into litigious arguments concerning the truth of any statements, for fear that, having stated those conditions by which their truth should appear, they might seem thereby to be conditioned and not to apply to some cases or conditions which we may have omitted; but we have endeavored, as much as possible, to give the details of our work, and to leave, as it were, the scaffolding by which our conclusions have been erected, in order that, in the varying conditions found in practice, it may be possible easily to perceive what influence they will have on the final results.

It is hard to meet practice—practical experience—with "theoretical notions." Anyone will admit that, especially if he has tried it. And so it is a very difficult thing to meet power users with long years of practical experience, with the message that power is costing them something. Most of them think that it is not costing them anything to speak of; yet how is it possible that small, isolated plants can generate power so cheaply when business enterprises which make this their sole work, and deliver comparatively enormous amounts of power, cannot do it? It simply is not possible! One reason why it seems to be so is because the power account is such a small one that a large portion of it, averaged over a number of years, is unwittingly not charged against it. But the main reason, it would seem, is this: Isolated plants and modern central station practice charge for power on two entirely distinct bases; the one, on the rated horse power of the plant, and the other on the actual horse power. A glance at the curves A and C will show the enormous discrepancy between them.

Time alone will tell which is actually the cheapest mode of power supply, all things considered; for, though it may seem impossible to frame a convincing argument to meet this so-called "practice," it seems certain that what the Darwinians would call continuous natural selection will form a very convincing style of argument, and is forming it. Everyone who has been watching electrical development for ten years past has seen this. It has gradually forced its way along lines which have proven to be thoroughly substantial; and once it gets a hold anywhere it never lets go. And this same natural selection is gradually weeding out the antiquated things, and ways, and people, whether they realize it or not; for, as Huxley once said of the problems one meets at every turn in life, "They don't even give a word and a blow, and the blow first; but the blow without the word; and it is left to you to find out why your ears are boxed."

If anyone thinks that these statements are not based on a broad foundation of fact, it is only because the facts lie somewhat below the surface; let him watch the course of events for the next twenty years, for the best arguments of electricity are in its actual triumphs. Truly, the populace is right when it says that "electricity is in its infancy;" it is, as far, at least, as its application is concerned.

A Patent Office Record Broken.

A dispatch from Washington of January 3 says: Last Friday's business was the largest in the history of the patent office, the fees received that day amounting to $9,376. Friday was the last day in which inventors who had patents in foreign countries and desired to take out similar ones in this country could take advantage of the old law which protected these patents for the full legal term in this country. Nearly 48,000 applications for patents were received by the office during the year, 4,000 in excess of the largest previous year.

LETTERS TO THE EDITOR

The Action of Alternating Enclosed Arcs.

IN the Dec. 11, 1897, issue of the "Electrical World," there was published an article entitled, "Tests of an Alternating Current Inclosed Arc Lamp," by Mr. M. H. Baker. While no special criticism of this article is necessary, most of the information therein contained being already well known and understood by those experienced in these matters, attention should be called to one or two statements which are misleading in their character, and which Mr. Baker would probably not have made had he had more experience with arc lamps than he apparently has had.

The first statement is that regarding the use of solid carbons. The article says: . . . "but the use of two solid carbons is practically impossible on account of the tendency to extinguishment." This may be the result of such tests as Mr. Baker may have been able to make, but is not so in fact; on the contrary, it is perfectly possible to use solid carbons in the inclosed alternating arc lamp and with no greater tendency to extinguishment than with cored carbons, and with even better results, provided one knows how to do it.

Again, the statement is made that "the arc does not with the cored carbons tend to climb up the side of the carbon, as frequently occurs with solid carbons," and that "the flaming effect . . . is invariably the sign of too great a current consumption for the size of the carbon."

These statements are not borne out by experience. The flaming effect mentioned takes place equally as well and as frequently with cored carbons as with solid carbons and has nothing to do with the current consumption ratio to the size of the carbons and can easily be remedied and prevented in any alternating inclosed arc lamp; provided one knows how to do it.

Again, among the alleged reasons for this abnormally large current consumption, is the one of "a lower frequency than that for which the lamp was designed, the last reducing the choking effect of the inductive resistance, thereby allowing more current to pass."

Experience in this direction does not corroborate this statement. On the contrary, it is perfectly possible to design an inductive resistance or choke coil which shall enable an arc lamp to run equally well on all frequencies of alternating current from 7,000 to 16,000 alternations, without any change of coil or lamp, provided one knows how to do it.

The inclosed alternating arc lamp is a comparatively new thing and is a study in itself, and much time and thought has been given to it by many able minds, and much valuable information exists on the subject, but which it known only to the discoverers thereof and which is at present kept as stock in trade and not given broadcast to the public, for obvious reasons.

It is to be feared that Mr. Baker has met with certain anomalies and difficulties in handling lamps of this description, and in lieu of absolute facts to account for them, is guessing.

Defects in Electrical Specialties.

The article of Mr. H. N. Gardner in The Electrical Engineer of November 25 on "Defects in Electric Specialty Designing," calling attention to faults and flimsy construction is well timed, only some of these defects ought to have been cured years ago. The faults that Mr. Gardner speaks of are so glaring that if a wireman has to go four blocks from his shop he had better take along extra material; that is, if working on a six light job he had better take along seven sockets, cutouts, etc., so as to be on the safe side. A man is likely to find screws missing, more likely screws that are so loose that they will not hold. Then another great fault is the small wood screw holes in some switches and other specialties.

Let me call attention to most cutouts and other electric appliances that show that the people who design them don't have to use them. That is, the screws and washers that hold the fuses and wires are so close up to the rim or shoulder that it is difficult to pass a wire or fuse around the screw.

But the worst of all is in one well known type of transformer which has a porcelain block in the top with all the terminals on it. When you want to run your wires into this transformer you will find the terminals for the primary in a straight line with the hole and bushing. But the secondary terminals are offset to one side and you have to bend a short square turn in your large secondary wire and sometimes break the rubber bushing in the case.

Then, again, canopies on combination fixtures should be made deep and long so that they would cover neatly the insulating joint and cutout and, say, two inches at the nipple on the gas pipe.

Probably this doesn't come under the same head, but could not some manufacturer make a common, cheap testing magneto that was not so large and did not weigh 8 or 9 pounds like those used at present?

HENRY FARLEY.

Galveston, Tex.

OBITUARY

Burr K. Field.

IT is with feelings of deep regret that we announce the death of Mr. Burr Kellogg Field, vice-president of the Berlin Iron Bridge Company, who died at his home, Berlin, Conn., on Thursday morning, January 13, after an illness of less than a week. His death was so sudden and his sickness so short, that few of his friends were aware that he was ill. Burr K. Field was born in May, 1856. He entered the Sheffield Scientific School of Yale University in 1874, and graduated in 1877 as a civil engineer. Immediately after graduation he commenced practical work among the railroads of the West. His principal experience was in connection with the laying out and building of the Northern Pacific. Mr. Field had charge of the locating and building of the branch connecting the Yellowstone National Park with the Northern Pacific. In 1882 he was appointed Superintendent of Bridges in the city of Philadelphia, which position he held for something over a year, when he resigned to accept a position as Assistant Engineer of the Berlin Iron Bridge Company. His advancement in that company was very rapid, and at the time of his death he occupied the position of vice-president with general charge of all the sales. Since his connection with the Berlin Iron Bridge Company its business has been much extended and its sales have increased wonderfully year after year. Mr. Field had no small part in the making of the enviable reputation which the Berlin Iron Bridge Company now enjoys, and his death will be a severe loss to his associates. He was an indefatigable worker, not only for the company which he had so faithfully served, but in everything he undertook; a true friend of his fellow-men, a devoted and earnest worker in the church, a staunch friend to the cause of temperance; active and energetic in every public position that engaged his attention. Mr. Field had a most pleasing manner, and he enjoyed an enviable reputation for his business methods and rectitude among the manufacturing corporations of the country. People who knew Burr K. Field best trusted him most. He is survived by a wife and two small children.

BOSTON BELL BUOYS.—Steamship people are greatly interested in the efforts to have the government permanently establish electric bell buoys on State ledge and Nix's Mate Since the steamship companies discontinued maintaining these guides to navigation, illustrated and described in The Electrical Engineer, complaints have been frequent, and it is the earnest desire of steamship captains and the shipping community in general that the government take early action in this important matter.

"I like The Electrical Engineer better than ever, and would not be without it."—A. W. McWilliams.

VOL. XXV. NEW YORK, JANUARY 20, 1898. No. 507.

Warning.

WE wish to warn our readers against an unsigned circular issued by one of our contemporaries accompanied by a fac simile of a letter from the advertising agent of one of the electrical manufacturing companies. Further publicity to the letter has been stopped on investigation, by the president of the company, and its publication forbidden. The circular that accompanies it aims to injure the whole electrical press, except the journal issuing it. Such efforts have failed before, and this, the latest, is equally deserving of scorn and contempt from all honorable men. If necessary we shall go into the details of this matter. For the present, we deem it sufficient to expose one more trick, where others have been exposed before.

Mr. Dana Greene on the Consulting Engineer.

IN the early days of electric lighting, when power and other electrical applications of the current were discussed as mere possibilities, the customer who desired to install a plant dealt directly with the manufacturing electric company. There were no consulting engineers, for the simple reason that all those who had sufficient technical electrical knowledge to have acted as such, found good and remunerative employment with the manufacturing companies. The latter, on the other hand, finding themselves unrestricted in the matter of design, were enabled to carry out their own ideas as dictated by experience. and hence developed rapidly a standard series of machines which could be duplicated indefinitely at reduced cost, and which have enabled them to comply very well with most of the conditions met with in practice. We believe that those conversant with the progress of the art will admit that much of the enormous expansion in electrical current application in the United States is due to the fact that the companies were thus left unhampered and that open competition among themselves served to develop higher and higher standards of efficiency accompanied by a reduction in cost to the user. But as time passed, the consulting electrical engineer entered the field, and it cannot be denied that a point has been reached at which it seems desirable that, for the benefit of all concerned, a better understanding should be arrived at between the customer, consulting engineer and the electrical manufacturer. That the consulting engineer fulfills a useful and important function, no one will deny, just as the architect is the proper intermediary between the owner and the builder. But where conditions may be laid down in specifications involving a departure from the established manufacturing standards, it seems worth while to inquire whether some mutual understanding cannot be reached to put the manufacturer to the least trouble and expense, which, of course, must in the end be borne by the customer. This whole question is very ably and impartially treated in the paper read last week by Mr. S. Dana Greene before the New York Electrical Society. Mr. Greene makes the point, first, that the electrical engineer is too apt to hold aloof from the manufacturer, on the assumption that his motives for approaching him closer may be misconstrued, or that by consulting him he might endanger his own standing as to technical competency. The result, as Mr. Greene points out, is that requirements are often called for which put the customer to additional expense, but for which there are no compensating advantages. One of the remedies suggested by Mr. Greene is that consulting engineers should avail themselves of all possible opportunities to visit manufacturing establishments and confer with the engineers of the manufacturer. This is excellent advice, and as no self-respecting electrical manufacturer has anything to hide or pretends to the employment of mysterious processes in its methods of manufacture, the following out of such a practice by consulting engineers can lead only to beneficial results for both. In fact, one could hardly wish for a better opportunity to learn than to have placed at one's disposal the experience of our manufacturing companies, gained at the expense of hundreds of thousands of dollars in experimental work. Mr. Greene does not go so far as to say that every condition can be met by a piece of standard apparatus, but insists that much of the special apparatus called for in engineers' specifications is unnecessary, and to that extent leads to a needless expenditure of money.

In the discussion which followed the reading of Mr. Greene's paper it was only too manifest that manufacturers treated engineers' specifications with an amount of consideration inversely proportional to their length. Of course, some of the consulting engineers present took the ground that the conditions of each individual case varied so much as to make a standard rather difficult to carry out in practice; to which Prof. Crocker made the epigrammatic reply that if such were the case the remedy would be in changing the conditions. To meet the existing state of affairs Mr. Greene suggests that a national body, such as the American Institute of Electrical Engineers, take up the matter with a view to formulating a code which shall embody such rules and regulations as will constitute a standard for current generating and motor apparatus to be followed by all alike, whether as manufacturers or as engineers. In our opinion this plan is a most excellent one and ought to be carried out at an early date. Indeed, we understand that the Institute has just such a plan under consideration at this present time, and we hope Mr. Greene's paper will expedite the work. The valuable assistance given by the Institute to the standardization of rules for the wiring and installation of electrical apparatus is fresh in the minds of all, and has been a great boon to the whole industry. It can make its influence in, and value to, the electrical fraternity still greater if it will now lay down some plan which will enable the manufacturers of generating apparatus to meet one another on common ground. We imagine that the consulting engineer would be the last one in the world to object to such a code, as it would at once relieve him of certain responsibilities and place upon him the burden merely of ascertaining whether the recognized standards had been lived up to in the apparatus furnished.

The Coming Electrical Exhibition.

MATTERS in regard to the Electrical Exhibition, to be held next May at Madison Square Garden, New York City, are now quickly shaping, and some forecast of the affair may be made with approximate accuracy. The last show, so brilliant a success, is only two years away, and one might reasonably have supposed that exhibitors were hardly ready or anxious for another. The contrary is the exact truth. The management is beginning to be somewhat perplexed as to the due allotting of all the space already contracted or applied for, and the letters they have received from numbers of intending exhibitors prove that a very lively interest exists everywhere on the subject. Two years ago, when business was bad and dull, the show was a splendid stimulus to trade and general inquiry for electrical apparatus. Is it not fair to infer that now, when all the wheels of industrial machinery have been set going again, and when everybody's purse is fuller, the opportunity to push business and make sales is an even better one than it was then? We believe that the coming show will be a better chance to display and sell apparatus than anything that has ever presented itself in this part of the country, and it is

evident that scores of shrewd exhibitors think so, too. The wealth and brains and energy and respectability of the electrical field are back of this show, and they may be relied on to see it through to an even more successful finish than that undertaken with so many doubts and fears during the panicky days of 1896. The management of the Exhibition is comprised of well known men who enjoy the respect of the community, and their efforts are being ably seconded in every influential direction.

It will be very interesting to see the trend of electrical affairs as manifested now, compared with only two years ago. Perhaps there is no art or industry to compare with electricity for steady, permanent gains combined with an incessant change of front and outlook. We are certainly far away from the situation of 1896 in many respects; yet it has virtually all been gain, and there is an entirely new aspect of affairs in many highly important branches. Of such matters, this Exhibition may be expected, even more than the last one, to give the public an authoritative and well rounded idea. It will be no fault of the management if it does not; for, while they take willingly their chances of financial success or failure, we know them to be more animated with the ambition of promoting the common cause in the eyes of the public, which, after all, is the buyer, user, or patron of everything that bears the name of electricity.

At the last Exhibition, springing as it did out of the displays made at each convention, there was given to the work of the National Electric Light Association a noteworthy impetus, which is gratefully remembered by the supporters of that body. This time, in view of the extraordinary interest then shown locally, the management have joined hands, on invitation, with the New York Electrical Society, the oldest electrical body in the country, to help it in its excellent educational work; and we shall be very much surprised if this common endeavor to impress the many-millioned public of Greater New York does not bring, as desired, large accessions to the membership of this useful, hard-working and creditable local society. Dr. Pupin, the president and his associate officers, have, we know, large ambitions for the prosperity and growth of the organization; and they will certainly spare no effort to enlarge, through this golden opportunity, its sphere of influence and service, while adding largely to the active membership. The Society has always gone along modestly but steadily, and it will now be advertised in a way that will enable it to derive direct benefit from its long career, stretching clear across two decades. It sprang out of the technical yearnings of a handful of telegraphers, many of whom have achieved eminence; while to-day, when it is 400 strong, the most prominent electricians in New York, like the youngest, feel honored to belong to it, or to be among its officers. Indeed, the American Institute of Electrical Engineers owed its origin to the feeling among members of the Society that there ought to be a national body on similar lines, and there has always been a large proportion of local Institute members in its ranks. All this augurs well not only for the success of the coming Exhibition, but for the growth of the New York Electrical Society as a local institution, and we urge upon all its loyal members to make the most of the present occasion, for it may be a long time before they get such another.

Telephone Lines as Common Carriers.

IT would appear that under the laws of Massachusetts, any telephone company is obliged to give any person or corporation, a telephone or telephone service, on payment of regular charges. We confess our deep doubt until recently that such a principle could be, or was being, enforced; and we imagine that the news will startle a good many people who have been discussing the "common carrier" aspect of the relations between "old line Bell" and the new "independent" telephone companies. The question came up at the famous Detroit independent telephone convention last year, and it seemed to be taken for granted that exchange of business would have to be fought for, and was in every case a hard won concession rather than a right. For ourselves, we have been unable to see why a Bell manager should not take all the business offered him, so long as it was paid for, being just so much additional income, no matter what its source; and that it was good financial policy to invite custom rather than repel it. Noting that the People's Telephone Company, at Haverhill, Mass., was delivering business to the local Bell Company, we have inquired into it, and Mr. N. N. Spofford, the local manager of this independent company, presents us with his data and views in regard to this situation. It appears that about two months ago he went to Mr. Keller, the well known general manager of the New England Company, and asked for a telephone on the pay station basis, and while Mr. Keller at first thought he could not do so, he had the good sense to make a contract with the People's Company on the regular basis, so much per year, for telephone office; and this is now on the pay station basis. In this way the main objection to the "independent" service—of its strict physical limitations—is done away, while it is obvious that the New England Company is also thus deriving revenue from its rival. There are, we believe, a few independent exchanges elsewhere turning in business to Bell companies, but it is not our information that they are on a pay station basis; though some of them may be. Mr. Spofford takes pride in having an instrument of his company in the office of the Western Union Telegraph Company. The People's Company has nearly 200 instruments in use, with a growing patronage, and is reaching out into other towns and cities; though with pay station privileges over all the Bell lines, it would hardly seem necessary to go in for much "extra territorial" extension. As we said last week, in regard to New York, there is an entirely new telephone situation developing, as this further instance shows, quite disregarded by the daily newspapers that jump in or jump on the telephone art once in a while; and we venture to suggest to them and others that it is worth keeping an eye on the new adjustments that are coming rapidly with the new telephonic times.

Municipal Ownership in Atlanta.

THE campaign for and against municipal ownership at Atlanta, Ga., has been lively, and has been attended by a number of interesting developments. It will be remembered that Atlanta has one of the best private plants, and one of the best services in the whole South, justifying the challenge which we printed recently from Mr. Atkinson, president of the Georgia Electric Co., to name any municipal plant that could show as good a record as their private one. At a recent public meeting in the city, Mayor Collier, when speaking on the subject was reminded by one of his audience of Mr. Carroll D. Wright's remark that there were no reliable statistics on the subject; and that the mayor's figures in favor of municipal plants were all wrong. That did not "phase" the mayor at all. His Honor immediately replied: "I happen to know something about Mr. Wright which would taint with suspicion anything he might say on this question. The statement of his former business partner is enough to condemn Mr. Wright, and, personally, I believe the charges are true." Cheerful, to say the least, and deliciously vague as most slanders are, Mr. Wright's only crime has been his endeavor to set on foot an investigation by the Government, as to this whole municipal plant business; and the moment some of our municipal friends—not all of them—are invited to stand up and be sifted they break out in abuse of the disinterested and matter-of-fact investigator; while the private electric lighting companies are doing all they can to aid the Government in its work. A fair inference would be that the contention of the companies that they give as good service as the municipal plants, at a genuinely cheaper rate, is well founded; and that the fantastic figures of municipal economy on the other hand will not stand daylight. However, we shall see, when Mr. Wright gets through. Meantime, Mr. Collier is swallowing his words, and retracting his abominable insult to one of the best officers in the Government employ—for the country is served by good men as well as bad. We are glad to append, and give publicity in full, to Mr. Collier's groveling retraction, as printed in the Atlanta Journal: "In my remarks at the Chamber of Commerce dinner a few evenings since I made a statement upon information, reflecting upon Mr. Carroll D. Wright, commissioner of the Department of Labor. Upon investigation I find that the information upon which this statement was made was erroneous in ascribing the alleged breach of faith to Mr. Wright. I make this correction, without solicitation, in simple justice to Mr. Wright, who, I learn, is an honorable, conscientious and painstaking official." We will simply add our own comment, to the effect that Mayor Collier's data in favor of municipal ownership has all been as well founded as his assault on Mr. Wright.

ELECTRIC TRANSPORTATION

The New Heilmann Electric Locomotive.

BY L. BAYLY.

(Electrical Engineer, Paris.)

THE first of Mr. Heilmann's electro-steam locomotives described, was tried and approved of at the close of 1893 on the Chemin de Fer de l'Ouest. The experiment took place between Havre and Beuzeville, the locomotive pulling trains of 206 tons up the gentle incline separating these two towns, at a speed of 25 miles per hour. Perhaps it will be as well to mention that the maximum speed as yet attained has been 68 miles per hour. Concerning the economy and practical advantages of Mr. Heilmann's system there still remains a good deal to be said, and indeed at first sight it would seem almost impossible for any practical utility to be got out of a machine working in apparent defiance of all the laws of the conservation of energy. Here, however, another train of reasoning comes into play, and the specific disadvantages of ordinary railway engines have to be taken into account before attempting to pronounce judgment on the Heilmann locomotive.

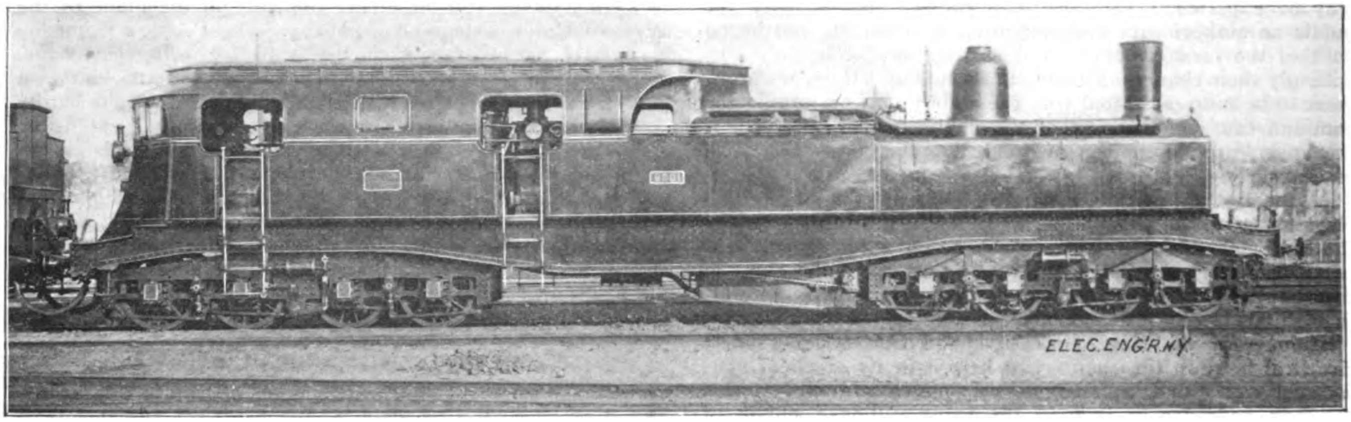

FIG. 1.—THE NEW HEILMANN ELECTRIC LOCOMOTIVE, WESTERN RAILWAY, FRANCE, CONTAINING A COMPLETE EQUIPMENT OF STEAM ENGINES, BOILERS AND GENERATORS.

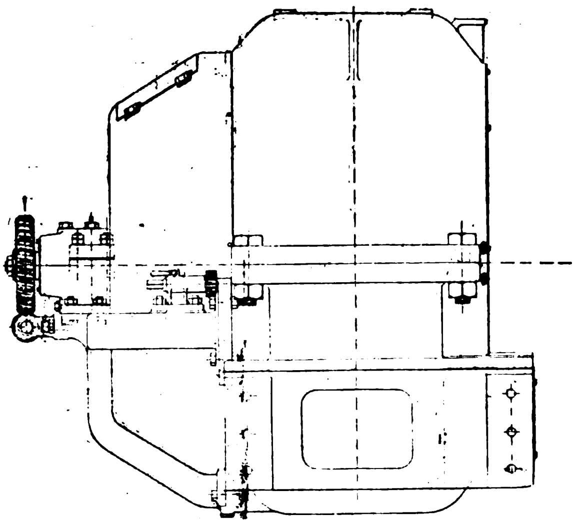
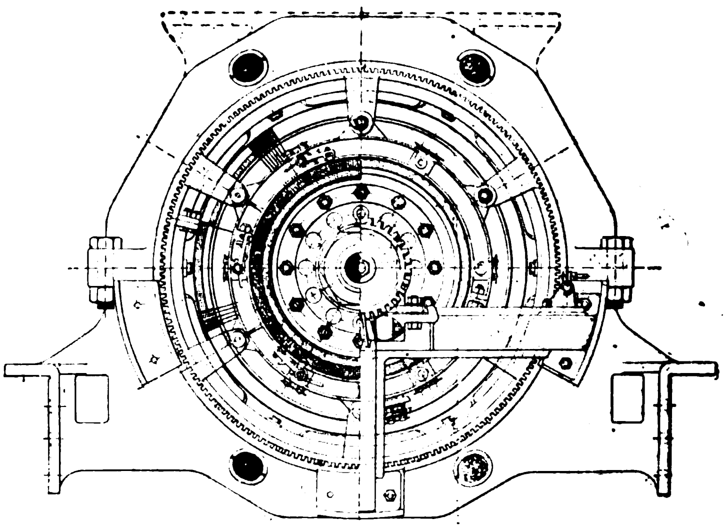
In fact, the popular idea about a miraculous speed being the aim and object of Mr. Heilmann's strivings is both erroneous and unfounded. Mr. Heilmann's desire has been to create a more perfect traction engine than any hitherto in use. A locomotive is, owing to its very nature, an uneconomical and variable contrivance. The principal aim of engineers has been to make it work economically between the largest possible limits. This aim is realized by the Heilmann locomotive.

The following is a detailed description of the latest type: Each engine, as will be seen in Fig. 1, is shaped something in the form of a 16-wheel bogie carriage. A tubular boiler of 185 square meters heating surface supplies motive power for two six-poled dynamos contained in the prow of the engine and capable of delivering a current of 1,000 amperes under an electromotive force of 450 volts. The engine in use is a six-cylinder one of 1,350 h. p.; the moving parts work in oil and the whole is concealed under a covering of steel, secure from dust and needing no especial attention.

The energy developed by the dynamos is communicated to 8 electric motors mounted directly on the axles of the wheels. These latter measure 45¾ inches in diameter and work independently of each other. As will be noticed from the illustration, one of the principal features of Mr. Heilmann's system is the evenness with which the weight of the whole structure is distributed over the axles, the maximum strain on each being about 3,300 pounds, instead of, as in the case of many other splendid engines, nearly three tons. The Heilmann locomotive, being built on the bogy principle, is also more flexible, and the enormously increased "grip" resulting from the large number of driving wheels, renders skidding impossible. The evenness of gait observed in the recent trial trips is partly due to the constancy of the motive power exerted on the axles, the imparted energy being uniform and invariable throughout the whole revolution.





FIGS. 3 AND 4.—GENERATOR OF NEW HEILMANN ELECTRIC LOCOMOTIVE, SIDE AND END VIEW.

As to the question of coal consumption, I might state that since the first experimental run between Havre and Beuzeville the consumption of fuel has diminished from 24.3 pounds to 13 pounds per mile. The Lentz type of boiler has, in the new form of Heilmann engine, been replaced by one of the

ordinary locomotive type. The following are some of the data of this boiler:

Grate area, 3.34 square metres; heating surface (furnace), 16.47 square metres; heating surface (tubes), 169 square metres. Total, 185.47 square metres.

Number of tubes, 351; exterior diameter of tubes, .045 metres;

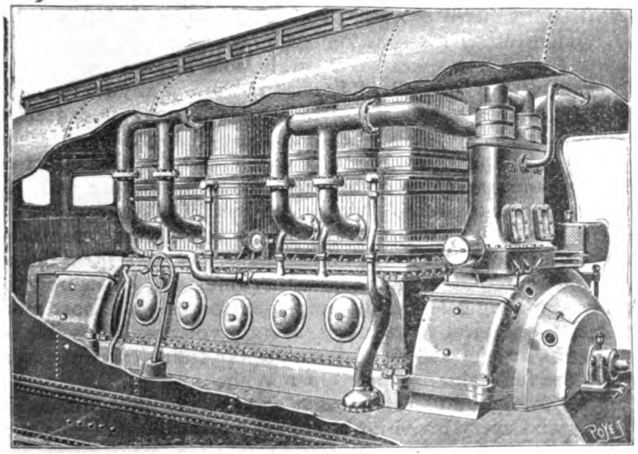


FIG. 2.—VERTICAL ENGINES ON NEW HEILMANN ELECTRIC LOCOMOTIVE.

length of tubes, 3.80 metres. The boiler is of iron and the draught is the ordinary locomotive exhaust draught.

The engines, which are shown in Fig. 2, are of the vertical pattern. This form was adopted partly with the intention of saving space, and of obviating the difficulties that might result from induced vibration in the bogy frame.

In employing a horizontal engine, more especially one working with its axis at right angles to the line of travel, complications need rarely set in, but in the case of a vertical engine they become almost unavoidable, the maximum inertia efforts taking place in a direction parallel to the oscillations of the engine frame on its springs. Should the strokes of the piston rods coincide even approximately with the swinging movements of the frame, the vertical vibrations may reach dangerous limits.

With a view to obviating this, the six-cylinder idea was

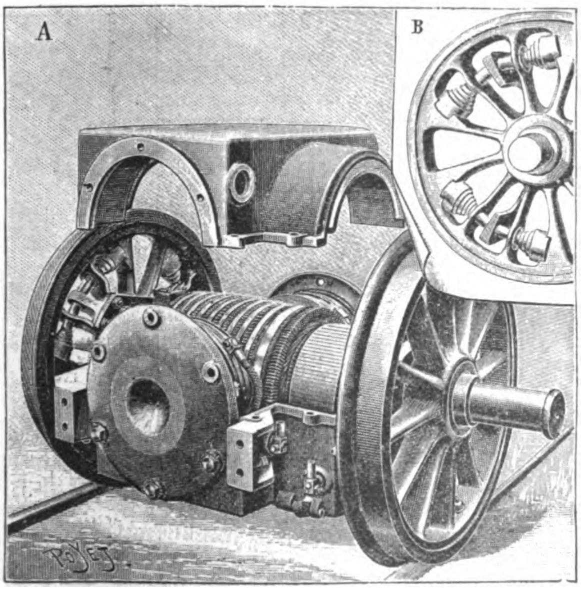

FIG. 5.—VIEW OF MOTOR AND SPRING CONNECTION WITH WHEEL.

proposed at one and the same time by Mr. Robinson and M. Mazen. The cylinders are each of them 13 inches in diameter and the maximum number of revolutions is 400. A governor of the centrifugal type is attached and the speed can be regulated between the limits of 100 and 450 revolutions per minute. The two dynamos are coupled direct, one at each end of the axle. They are from the workshops of Brown, Boveri & Co., and are coupled in parallel. They are 6-poled, the armature being a drum with the coils wound in parallel, air-spaces being left between the iron discs to insure ventilation. The current is collected by six sets of carbon brushes. The engravings, Figs. 3 and 4, show the construction of the dynamos. An auxiliary dynamo has also been added, serving both as exciter and for the purpose of feeding the train lamps. It is driven by a 28 h. p. Willans engine, and gives a current of 140 amperes under an electromotive force of 115 volts.

The motors are four-poled, wound in two coils. The magnets are of steel and are bolted direct to the bogy-frame. The upper magnet is removable, as shown in Fig. 5, thus permitting the inspection and repairing of the armature. The latter is multipolar series drum wound and the current, as in the case of the dynamos, is collected by carbon brushes.

The normal capacity of each motor when the locomotive is running at 75 miles an hour is 125 h. p., which corresponds according to calculation with an approximate pull of 748 pounds at the axle of each wheel. The maximum total effort exerted on each wheel axle during the trial trip amounted to 2,640 pounds. Fig. 6 shows the motor in sectional view. The motion of the armatures of the motors is transmitted to the wheels through the medium of a set of springs, as shown in Fig. 5 B. By this arrangement all shocks at starting are avoided. A controller allows the eight motors to be worked either in groups of four or all in series and a second switch gives a reverse movement by the reversal of the current in the armatures. Each motor has its own amperemeter, cut-out and fusible plug.

There are two cabs from which the engine can be worked,

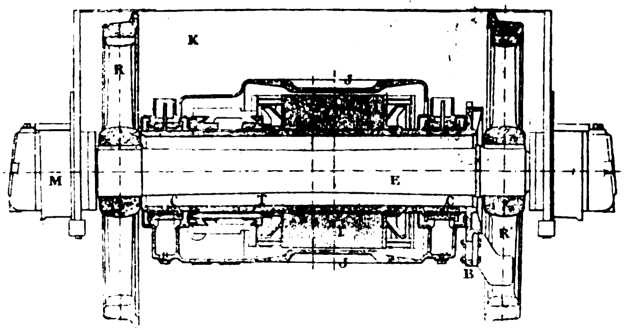

FIG. 6.—MOTOR MOUNTED ON AXLE, HEILMANN ELECTRIC LOCOMOTIVE.

one in the front of the steel prow, the second, as in ordinary railway engines, behind the boiler. The whole can, therefore, be worked both ways, but the first named method, viz., from the prow, is obviously the most convenient. The engraving, Fig. 6, shows the coupling of motor and shaft.

Following are the general dimensions of the locomotive: Length between buffers (total), 52 feet; distance between bogies, 39 feet; width of cab at prow, 8 feet 6 inches; extreme height (rails to funnel), 13 feet 5 inches. The efficiency of the whole may be figured as follows: The power delivered into the engine cylinders is estimated at 1,305 h. p. The efficiency of the engine is 90 per cent.; that of the dynamos 95 per cent.; that of the motors 90 per cent. This gives, taking all losses into account, including 2 per cent. in the conductors, a total of 1,154 h. p., or nearly 850 kilowatts at the dynamo brushes. These figures vary very little between the extremes of speed at which an express train is compelled to run.

If we now try to estimate the dynamic output of the engine, taking into account the amount of power absorbed by the machine itself, i. e., the difference between the power delivered at the wheel axles and that delivered at the draw bar, we find that this difference varies slightly with the speed, and with the weight of water, etc., carried.

The following are M. Drouin's figures: Supposing the locomotive to weigh 115 tons and to carry 17 tons of water. At a speed of 63 miles the pull exerted at the wheel axles will amount to 5,940 pounds. The energy necessary for overcoming the weight of the engine will be $(115+17)\times 7 = 2,032$ pounds. This gives a power of 3,907 pounds at the draw bar. Expressed in horse power, the available power at the draw-bar is 657 horse power and the output of the engine stands thus: $657 \div 1,350 = 47.1$ per cent.

The efficiency of any and every locomotive is at all times subject to considerable variation. The problem has been to construct an engine that will remain economical between the widest possible limits. This ideal has been realized by the Heilmann engine.

The Caffrey Trolley Road Wagon.

BY W. G. CAFFREY, RENO, NEV.

IN the consideration of the subject of motor vehicles of the trolley type as an economical method of freight transportation, several important points arise at once. Can a vehicle be produced to compete successfully with existing methods of transportation? This is the most important point and if settled satisfactorily it will surely point out the line of development to be followed. The resistance to traction of the average railroad, including the various curves, can safely be placed at 15 pounds per ton; the fuel consumption at 7 pounds of coal per h. p. hour; the average running speed of freight trains 20 miles per hour; the schedule averaging about 10 miles per hour, and the actual working time of engine and crew brings it to about 6 miles per hour. The cost of construction varies with the country traversed, the traffic to be handled and the weight and capacity of its rolling stock. A safe average assumption of cost of roadbed and equipment of a modern road would be about $50,000 per mile.

FIG. 1.—SIDE VIEW CAFFREY WAGON, SHOWING TROLLEY ATTACHMENT.

With this data as a basis to work upon, a careful calculation as to the probable cost per ton mile for freight transportation gives us at once the maximum amount which a motor vehicle could command; but if this cannot be reduced, it is more than probable that capital would not touch it. A careful analysis of the situation shows that the first cost or capitalization is a prime factor. Interest will keep running up when everything else has sense enough not to move.

The main cost of a railroad being its roadbed, eliminate this element from the motor vehicle line as much as posible. Grades in railroads occupy a large proportion of an engineer's thought not so much as to the cost of climbing them, but how steep a grade they can stand. In a motor vehicle system the thought is how much will it cost? To eliminate the roadbed feature of a railroad in a motor vehicle system suggests the existing highways, used in a manner not to interfere with their present use.

This brings us to the strength of the bridges and culverts along these highways and the present maximum loads hauled thereon; the character of the roads and the speed with which motor vehicles can safely and economically traverse them. These settled, and the tractive resistance to be encountered and the power required by this system can be closely approximated.

In the comparison of a motor vehicle with a railroad the tractive resistance immediately becomes an important feature. Spring suspension, roller bearings and wheels of comparatively large diameter and wide tires all tend to reduce it. Not being able to reduce it to an equality with railroad practice, we must then endeavor to meet the difference by producing power more economically than railroad practice shows. The result of this comparative analysis suggests a system as follows:

A system using the existing highways as much as possible, having the trolley wires on a single pole line on one side of the road, with wagons flexible enough to run anywhere along the road, of general appearances similar in a great degree to those now in use—using wheels of somewhat greater diameter and of considerable width of tire to increase tractive effort or adhesion and prevent mud and soft roads interfering with the traffic to a great extent; a moderate speed of about 6 miles per hour and vehicles not to weigh over 7 tons; tires smooth on the exterior, so as not to cut up the roads, but pack them down; utilizing water power wherever obtainable, and, when not, the best engineering talent to be employed to design a most modern and economical steam plant, using a voltage, if possible, of 1,000 volts instead of 500. Scheduling the trains carefully so as to get the full value of the copper in the system.

Such a system, utilizing the best engineering skill obtainable, and any and every invention designed to increase the efficiency of the system can transport freight in open competition and parallel any railroad in existence, and prosper on rates one-half less than any railroad can. For high speed express and passenger traffic the railroad will be the one par excellence. For moderate speed and cheap transportation of freight and passengers the motor trolley vehicle will be the result. Canals will again assume their former activity as freight highways for the motor trolley vehicle will take the place of the tired mule.

To carry out a system of transportation as herein contemplated, the writer has laid down the following requisites which he considers necessary for a successful solution of such an undertaking. The freight motor wagon will correspond to the following specifications:

Rear driving wheels, 8 feet in diameter, with smooth steel tire 26 inches wide; roller bearings to fit the spindle and geared to the motor. The rear axle to have a vertical movement, subject to the opposition of elliptical springs. There will be motors for each rear wheel and spring suspended from the main frame. Each motor at its intermediate gear is to have a band brake, which can be operated both at once or separately; also a clutch which can be used to throw both motors together when required.

FIG. 2.—REAR VIEW, CAFFREY ELECTRIC TRACTION WAGON.

Motors are to be of the regulation street railway type, but

rated differently and controlled by the regular series parallel controller; all the apparatus to be suspended below the body of the wagon. In front will be the controller lever, the band brake, levers, the clutch lever, the lever controlling the trolley cord and the air brake valve and steering lever or wheel.

The front axle will be pivoted at its center to a forging spring suspended from the frame and have a vertical movement at its outer ends of 12 inches. The wheel spindles to be pivoted as closely as possible to the hub, with arms extending forward for steering or turning. The front wheels are to have 4 feet diameter and 16-inch tires.

The trolley consists of two metallic frames connected together by an insulated lazy tongs arrangement. Each frame carries two trolley wheels running on top of trolley wire and kept there by two locking wheels beneath, which, when passing a pole recede in a horizontal plane sufficiently to pass the wire support. The wire supports are of malleable iron and attached to the side and insulated from the pole; on the side of the trolley facing the road four steel guides are attached to lazy tongs, to which the cord or cable conveying the current to wagon is attached. These guides keep the cord central and brace the trolley. The trolley cord or cable is of sufficient length to permit the wagon to run 200 feet away from the pole line and is reeled or unreeled from wagon.

An experimental wagon built to test the practicability of the scheme outlined above has been built and is illustrated in the accompanying engravings. Figs. 1 and 2 show the wagon in side and front views. This wagon operated very successfully. It ran within 2 feet of the pole line and 200 feet away, in and out among teams and in no case did it hit or scare any of the numerous teams. The wagon is equipped with a 2 h. p. crane motor of the Westinghouse pattern, controlled by a commutator controller. The power generator was a 5 h. p. Westinghouse dynamo. With this outfit on a level hard road we acquired a speed of 15 miles per hour with a load of 2,500 pounds on the wheels. Fig. 3 gives the details of a 30-ton wagon.

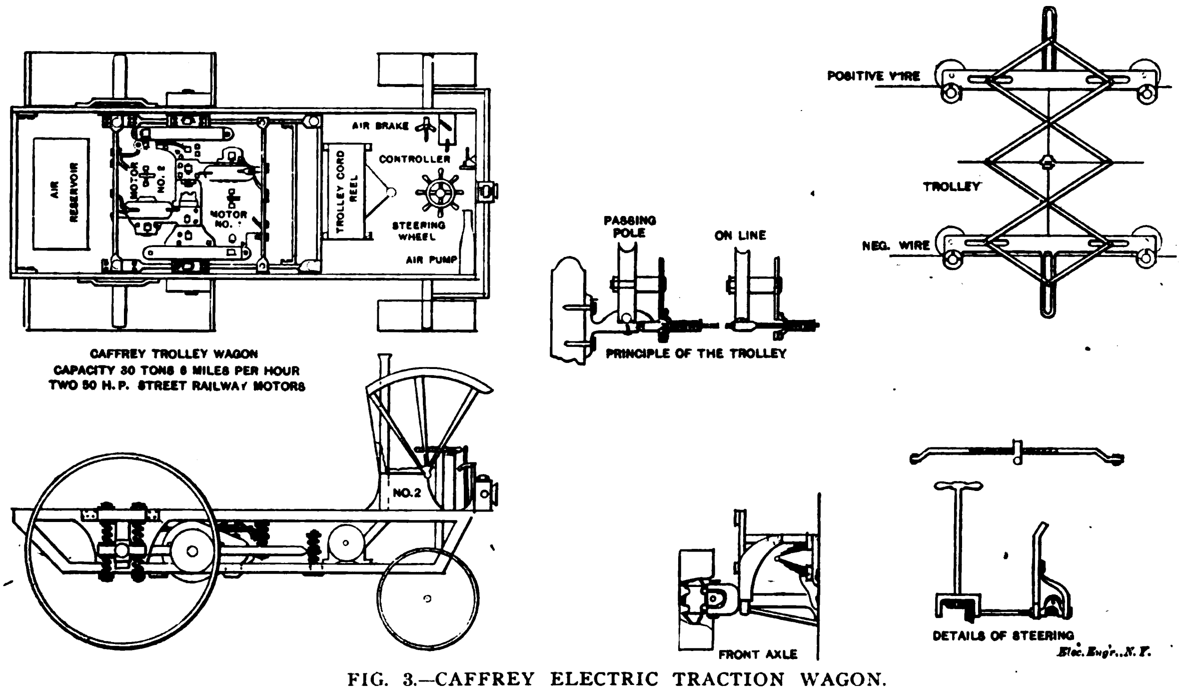

FIG. 3.—CAFFREY ELECTRIC TRACTION WAGON.
(Details of Construction of Motor, Trolley, Steering Gear, Etc.)

A Projected 34 Mile Road From Rochester.

There is a movement on to build an electric road between Rochester, N. Y., and Mt. Morris by way of Avon and Geneseo, a distance of about 34 miles. Capitalists of the above named places are considering the matter, especially at Geneseo and Mt. Morris, where the accommodations by rail are very poor. The Rochester Street Railway Co. published a notice in the daily papers a short time ago to the effect that they would do all possible to carry out the project. C. F. Whiting, superintendent of the Avon Electric Light and Power Co., of Avon, N. Y., is promoter of the scheme.

Data as to the Electrical Operation of the Proposed New York Underground.

We are indebted to the courtesy of Mr. W. B. Potter, engineer of the railway department of the General Electric Company, in response to our application, for the subjoined data furnished to Mr. W. B. Parsons, chief engineer of the New York Rapid Transit Railroad Commissioners, as to the cost of electrical apparatus and equipment for the proposed underground road:

We take pleasure in submitting herewith the data from which we prepared our estimate recently given you on cost of electrical apparatus and equipment for the New York Rapid Transit Railway. The train service specified between Post Office and 97th street consists of three-car local trains on one minute headway at schedule of 13 miles, including stops, with stations 1,500 feet apart; and also five-car express trains on two minute headway at schedule speed of 35 miles per hour, including stops, with stations 7,500 feet apart; the road to be four track between Post Office and 97th street.

North of 97th street the road to divide into east and west branches, both local and express trains from below 97th street running alternately on one branch and the other above junction point. The train service is similar for both branches and considering either branch by itself, there would be two of the three-car locals for each five-car express from below 97th street, this giving a headway between trains of one and one-third minutes for each of the branch lines.

The service on these lines for the three-car trains would be equivalent to a one-minute headway and for the five-car trains to a two-minute headway, both three and five-car trains running at schedule of 18 miles per hour, including stops, with stations 3,000 feet apart.

Based on the train service as above given, following is an estimate of power required for the different character of trains:

Route. Post Office to 97th street.

Distance, 7 miles.

	Character of train. Local.	Express.
Schedule speed, including stops, miles......	13	35
Number of stops..........................	25	5
Distance between stations, feet............	1,500	7,500
Headway between trains, seconds..........	60	120
Duration of stops, seconds................	10	15
Number of cars per train..................	3	5
Weight of train, loaded, tons..............	60	140
Maximum speed, per hour, miles...........	24	63
Assumed tractive effort per ton, pounds....	120	140
Corresponding watt hours per ton mile.....	127	159

	Character of train. Local.	Express.
Total tractive effort, pounds	8,000	19,600
Traction coefficient of motor car, per cent	10	12
H. P. per train at axle	38½	552
H. P. per train at power station	177	1,105
Total number of trains	65	12
Total H. P. at power station	11,500	13,300
Number of motors per train	4	8

Route above 97th street, East and West branches, both being similar, are considered together.

Distance, 7 miles.	Character of train. Local.	Local.
Schedule speed, including stops	18	18
Number of stops	12	12
Distance between stops, feet	3,000	3,000
Headway between trains, seconds	120	240
Duration of stops, seconds	10	10
Number of cars per train	3	5
Weight of train, tons	80	140
Maximum speed, miles	31½	31½
Assumed tractive effort per ton, pounds	85	85
Corresponding watt hours per ton mile	119	119
Total tractive effort, pounds	6,800	11,900
Traction coefficient of motor car, per cent	8½	7½
H. P. per train at axle	115	200
H. P. per train at power station	230	400
Total number of trains per branch	23½	11½
Total for both branches	47	23
Total H. P. at power station	10,800	9,200
Number of motors per train	4	8

Summary of service, Post Office to 97th street:

	Local.	Express.
Schedule speed, including stops, miles	13	35
Number of trains	65	12
Number of motor cars	65	24
Number of trail cars	130	36
Total H. P.	11,500	13,300

Above 97th street, including East and West branches:

	Local.	Express.
Schedule speed, including stops	18	18
Number of trains	47	23
Number of motor cars	47	46
Number of trail cars	94	69
Total H. P.	10,800	9,200

Grand total of system:

H. P. at power station	44,800
Number of motor cars	182
Number of trail cars	329

In preparing estimate on cost of investment, we have allowed for certain reserve, both in power station and in number of cars, as you will note. The investment is based on a single power station located on the east branch where it crosses the Harlem River. Have estimated on three-phase generating apparatus with rotary converter substations located at different points of the line, as required. The cost of power station equipment for stations of this size would not be materially affected whether one or two stations were built, nor would it be affected by the number of substations within probable limits.

The estimate as prepared contemplates eight or ten substations feeding directly into a third rail of 100 pounds cross section or larger, thus dispensing entirely with low potential feeder copper. The items of lighting equipment for the tunnel and stations, and also tools, are a matter of conjecture and subject to modification.

Estimate on cost of the electrical equipment and rolling stock, complete, ready for operation, based on previous assumptions, is as follows:

Power station, 50,000 h. p., at $63	$3,150,000.00
200 motor cars, at $10,800	2,160,000.00
350 trailers, at $3,000	1,050,000.00
Rotary converters and transformers, 50,000 h. p., at $16	800,000.00
High potential feeder line	360,000.00
Feeder ducts, insulators, etc	54,000.00
Third rail, 56 miles, at $3,500	196,000.00
Lighting equipment of tunnel and stations	25,000.00
Tools	50,000.00
	$7,845,000.00

The cost of power station, as given, does not include real estate, the items being made up as follows:

	Per H. P.
Building and foundations	$12.00
Engines and condensers, erected	18.00
Boilers, erected	15.00
Generators and switchboards, erected	11.00
Piping	4.00
Stack	2.00
Feed pumps, etc	1.00
Total per h. p.	$63.00

Bonding of track I have assumed at $700.00 per mile, which is rather in excess of usual cost, but the work in this case needs to be very substantially done.

Conduit ducts for feeder wire will cost from 12 to 18 cents per foot, depending upon number of ducts and labor incidental to laying them.

The motors for each motor car equipment have a nominal rating of 175 h. p. each. This rating, in accordance with standard practice, is based on a given temperature rise for an hour's run at rated load. Under operating conditions the motors will perform an average of from 20 to 30 per cent. of this rated horse power within safe temperature limits.

As regards cost of power, many modern power stations are producing it at the switchboard for four mills per horse power. Several records that we have give as low as 3.8 mills. This cost per horse power hour includes everything incidental to the generation of power, and comparing the operation account of a number of power stations in the vicinity of New York, with coal at $2.20 per net ton, I find that the average cost for the different items per horse power hour is about as follows, in percentages:

	Per cent.
Fuel	48.
Operation (labor)	35.
Operation (supplies, oil, waste, etc)	9.
Maintenance (labor)	5.
Maintenance (supplies)	2.5
Maintenance (building)	.5
	100.

There are numerous details regarding feeder distribution, train control, sectioning of third rail, etc., that I have not touched upon and, being details that are necessarily affected by plans as finally decided, presume you do not care for a discussion of them at present.

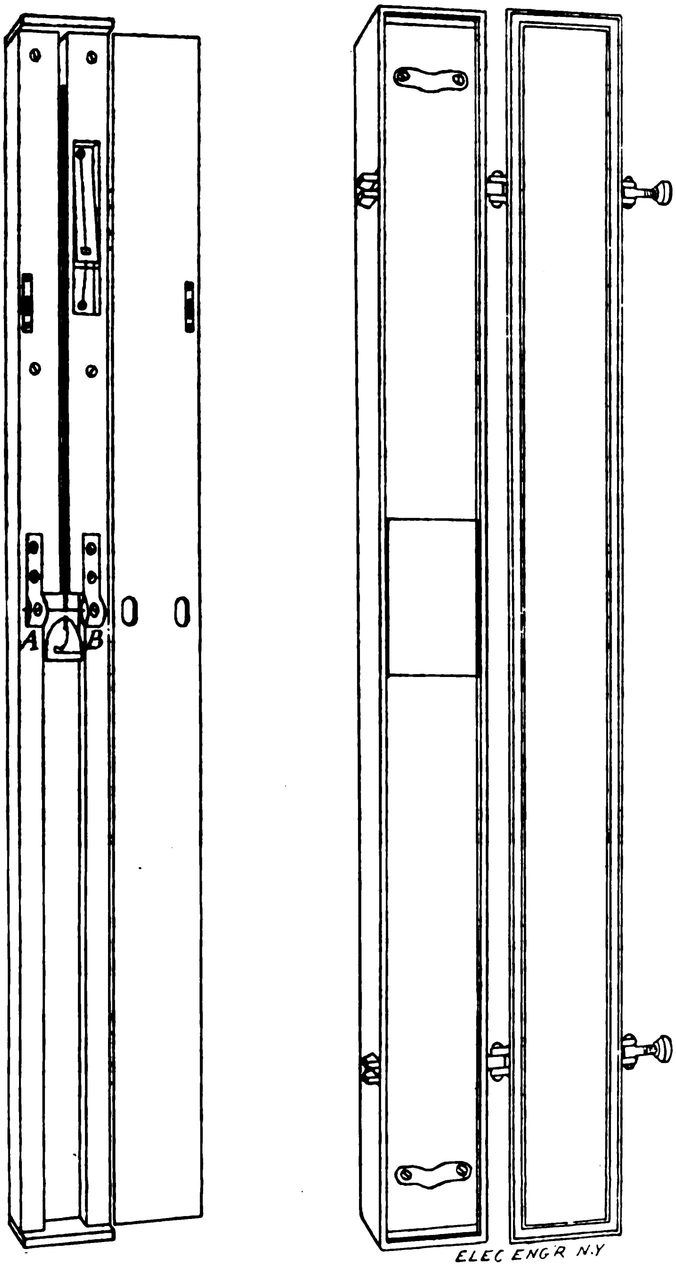
The Cravath Excessive Current Recorder.

It is generally admitted that a city electric road requires from 15 to 25 per cent. more energy to operate it than would be required were all the motormen to handle their controllers carefully and intelligently with a view to using as little as possible without getting behind time. No small part of this waste is due to a too rapid turning on of the power in starting, thereby spinning the wheels, throwing away the efficiency of the series combination on the series parallel controller and overloading armatures by cutting in field shunts too soon. This practice is also detrimental when carried too far, because with the sizes and types of motors commonly employed it results in overheating the motors, besides causing excessive fluctuations in the voltage and requiring the constant running of a large capacity of generating machinery.

The Cravath excessive current recorder is designed to afford an electric railway management a knowledge of the excessive use of current by various motormen without interfering with the operation of the road. It is a simple apparatus designed to go on each car and keep a continuous record of the efficiency of each motorman along the line indicated, and is the only instrument of the kind on the market. The presence of such a recording instrument has the practical effect of making all the motormen careful and efficient. This has been practically demonstrated on one road equipped with them where the saving in actual coal consumption amounted to 15 to 20 per cent. after the recorders had been on long enough to educate the motormen in economy.

The instrument consists of two parts. The recorder proper, Fig. 1, is given to every motorman before he starts out on his

run, is put in position on the car by him, and at the end of the run turned in by him at the office. This recorder fits into a recorder case, Fig. 2, which is a fixture on the car, and contains the car circuit terminals. The act of pushing the recorder into its case closes the car circuit through the recorder, and unless the recorder is in its place the car circuit is open and the motorman cannot run his car. The recording device con-



FIGS. 1 AND 2.—CRAVATH EXCESSIVE CURRENT RECORDER.

sists of two very simple elements, a horizontal German silver wire held between the terminals A B, and of such cross section as to be heated by the current operating the car, which flows through it, and a thin strip of alloy of low melting point. This strip of alloy is supported in vertical guides above the wire and held against the wire by a weight champed to its lower end, as shown in the illustration. When the temperature of the wire has reached a certain point due to the passage of current through it, the wire begins to melt its way through the alloy strip and the strip and weight descend. The amount of strip melted through in a day, divided by the car mileage, is used as a record of the motorman's efficiency.

In practice the hot wire is made of such a size that a good man under ordinary conditions will melt through but little of a strip, the strips being 17 inches long, while some of the more careless men will go through the full length. The proper size of wire is determined by actual experiment with a careful motorman in regular service, and of course will need to be varied with the weight of the car and local conditions. The instrument records according to the square of the excessive current flowing.

As to practical operation this recorder is ideally simple. When the motorman is called for his run he is given a locked recorder containing a fresh strip of alloy. As is seen by the illustrations it is a strong wood box. It contains simply a weight, an alloy strip, a hot wire and two terminals, which terminals are provided with switch lugs on the back which fit into switch jaws in the iron recorder case on the car, to complete the circuit when the recorder is pushed into position. It contains also an automatic short circuiting device as a precaution to prevent injury to the instrument or stoppage of the car should the hot wire melt under an abnormal current. This, however, seldom occurs.

It is but the work of a few seconds for the motorman to shove the recorder into the case, close the case door and be off. At the end of his run he turns it in at the office and the clerk unlocks and reads it at his leisure. If more than a small fraction of the strip is melted through a new one is put in and the old one thrown into the scrap pile to be sent back for remelting and rerolling. The cost of these strips is thus made nominal. The refilled recorder is then put in the pile ready to go out. A record of "miles run" and "inches melted" is kept for each man, and the clerical work is so slight that it can in most cases be done in spare moments by men already employed.

While a man may have bad luck as to delays and heavy loads one day, such things will not happen to the same man all the time, so that the comparative record is perfectly fair. This device is manufactured by the Cravath Manufacturing Co., 825 Monadnock Building, Chicago., of which company Mr. J. R. Cravath, the inventor of the device, is president.

Public Control, Ownership or Operation of Municipal Franchises?—III.

With Special References to Electric Lighting.*

By R. R. BOWKER,

(Vice-President and General Manager New York Edison Co.)

MUNICIPAL INDUSTRIES IN THE GREAT CITIES.

THE pages following give the facts and figures as to municipal industries in the great cities of the world, chiefly as to lighting, but with reference also to other industries, when the experience is significant or distinctive:

PARIS.

Paris has its gas supply exclusively from a private company, the Compagnie Parisienne, resulting from a consolidation a generation ago, covering the city and suburbs under an exclusive concession given in 1855, and extended under the contract of February 7, 1870, through 1905. This had in 1896, in addition to 93,044 burners for public lighting, 347,295 customers; the year's consumption was 318,020,060 cubic meters and the receipts from sale of gas 80,876,336 francs. Under the contract with the municipality, its price to private consumers is 30 centimes per cubic meter ($1.64 per thousand cubic feet) and to the city half that rate. In 1896 it paid to the city 5,470,187 francs in royalties of 2 centimes per cubic meter sold, 200,000 francs for sub-soil privileges, 8,800,000 francs as half of its surplus profits, in addition to 1,235,002 francs for expenses in the maintenance and care of street lamps—in all 15,705,189 francs;

*This paper is written from the point of view of the economist and citizen, but with the data and experience gained as the executive of the New York Edison Company. To my mind, this should not involve opposition of interests; as he most serves his party who best serves his country, so he most serves the interest of a public-service company who best serves the public. I mention the relationship, however, to forewarn readers of any unintentional bias. It is difficult for any outside the business cited, in an academic discussion, to obtain real bases of comparison.—Reprinted by permission from Municipal Affairs, the Reform Club Quarterly.

and to the State in various taxes, 1,095,720 francs; together, 16,800,910 francs, or the equivalent of 5.3 centimes per cubic meter, or 20 per cent, of its total receipts from sale of gas. Thus, out of $1.64 charged per thousand cubic feet, 28.6 cents is returned to the city of Paris in a tax actually paid by the gas consumer, without which the price would be $1.35 per thousand cubic feet. The Compagnie Parisienne has issued 336,000 shares of 250 francs, of which it has amortized 188,513, leaving 147,487 shares (or $7,374,350) present share capital; it has issued 553,332 obligations of 500 francs, of which it has amortized 237,136, leaving 316,916 bonds (or $31,619,600) outstanding. It has paid 5 per cent. on its bonds and in 1896 the enormous dividend of 26 per cent. on its stock, an extraordinary showing of what can be done by a private company occupying an exclusive field in a great city.

Paris has six electric lighting companies, each occupying a "secteur" of the city under a municipal concession for 18 years expiring in 1907-8, and a small municipal plant in the central market house. These seven systems supply 744 street and 7,056 commercial arc lamps and 416,000 incandescent lamps (chiefly 10 and 16 candle power) and there are 4,000 arcs and 286,900 incandescent lamps on private plants, making a total electric installation for all Paris of 11,800 arc and 702,900 incandescent lamps. There are but 500 electric motors in all Paris, power being supplied largely by compressed air. The municipal contract limits the price to 15 centimes per hektowatt hour (30 cents per unit) for lighting and 6 centimes per hektowatt hours (12 cents per unit) for power purposes. The average price is about 11 centimes per hektowatt hour without lamps, somewhat above the American maximum price of 1 cent per 16 candle power lamp, which includes lamps. The six private companies have a share capital of 48,000,000 francs and obligations of 15,500,000 francs, and one company has a floating debt exceeding 30,000,000 francs. Three of the companies pay 5, and one 4 per cent. dividend; one has never paid dividends, and one is just beginning.

The electric light companies have recently petitioned the municipality to extend these concessions for a further period of 25 years, and M. Charles Bos, a member of the Municipal Council, has presented (1897) a most careful and valuable technical report on this question. He states that the present price of electric current is practically equal to the price of gas burned in the ordinary way. The distributing system in Paris is chiefly under the sidewalks and the city retains the right to take over this "canalization" at a fair valuation. The city charge for replacing pavement is stated at 8 francs per square meter ($1.30 per square yard) for stone on concrete and 16 francs ($2.60 per square yard) for asphalt, and for sidewalks 5 to 6 francs per square meter. M. Bos states the cost of coal in Paris at 32 francs per ton, in Berlin at 21.5 francs and in London at 24 francs.

Paris also includes in its sub-soil system ducts for compressed air for power purposes, and a pneumatic service for postal purposes. The telephone system in Paris is in the hands of the government and is much behind the age; until recently calls were made by the name and address of the subscriber.

Oustide of Paris there are recorded in the French cities and towns 28 municipal and 378 company plants, now very important.

BERLIN AND OTHER GERMAN CITIES.[1]

Berlin has a municipal gas plant supplying the city except in the central district, which is supplied by a gas company organized in 1825 by English capitalists, whose charter proved to be an exclusive and perpetual privilege for the heart of the city. The municipal plant produced in 1895-96, 86,213,953 cubic meters, and the private company 31,528,804, together 117,742,757 cubic meters. The municipal price is 16 pfennigs per cubic meter ($1.08 per 1,000 cubic feet) for lighting and 10 pf. (67c.) for heating, and the price from the private company is 15.2 pf. ($1.02) for lighting and 9.5 pf. (64c.) for heating, the private company having kept its price 5 per cent. below that of the municipal supply.

Berlin has but one electric lighting company, the Berliner Elektricitäts Werke, which had in 1896-97 4,067 customers, 196,076 incandescent lamps, 196 street and 8,977 commercial, a total of 9,173 arc lamps, and 7,475 horse power in motors, etc. It delivered in the year, 14,200,000 units and had gross receipts from current of 5,134,300 marks, nearly $1,280,000. It paid to the city under its contract 513,430 marks, being 10 per cent. on the returns for current, etc., and 273,948 marks, being 25 per cent. of its surplus profit above 6 per cent. dividend, together 787,378 marks ($186,000) exclusive of taxes. It also paid into a reserve fund required by law 112,083 marks, into two employés' benefit funds 93,750 marks, and a dividend of 12½ per cent. on the share capital. The base price is 3 pf. (¾c.) per 16 c. p. lamp hour without lamps, being 15 cents per unit, and for power 16 pf. (4c.) per unit. Lamps are supplied at an additional charge of 5 marks ($1.20) per 16 candle power lamp per year. On incandescent light discounts are allowed of from 5 to 25 per cent. according to the number of hours' use of the lamps, and in addition from 5 to 20 per cent. according to the total amount of current consumed. The average return of the Berlin Company for all services, including a supply of current for three lines of electric railways, is about 9 cents per unit. In addition to the company's service there are 348 private plants with 3,690 arc and 85,000 incandescent lamps. Berlin also has a "blow post" sub-soil service in connection with its post-office and a governmental telephone service, which, like that of Paris, is much behind the times.

Outside of Berlin there are in German cities and towns 207 company and 41 municipal plants, the leading examples of the latter being in Frankfort, Dresden, Hanover, Dusseldorf, Cologne, Nuremberg, Bremen, and now in Munich. Vienna has had a gas company, organized by English capitalists, but the Socialist power known to us under the mask of anti-Semitic agitation has carried the point of erecting an operating plant, without taking over or making allowance to the gas company for its existing works, a striking example of municipal confiscation. Electric lighting is supplied by five or more private companies, one of these having one of the largest stations in the world on the banks of the Danube. Buda Pest is supplied by two electric lighting companies, one distributing high tension and one low tension current, and is especially noteworthy for its handling of the transportation question, having a trolley line operated by a private company through underground ducts, the first important installation of its kind, and a rapid transit tunnel electric railway operated by the same company.

LONDON.[1]

London does not own its water front, except along the embankments made during the past generation, and its magnificent system of docks is the work of several different corporations, one of which has a capital of £5,000,000.

London receives its water supply from eight private companies, the oldest, dating from 1608, and one other taking water from the river Lea, a third from chalk pits in the hills of Kent, the other five from the upper Thames, filtering the water through large settling pools. Water rates based on rental value must be paid by the tenant in advance; the house owner must lay the pipes communicating with the mains, except for houses renting under $50 per year, for which the company must on request furnish service pipes, charging for them an additional annual charge, in which case the owner is responsible for the water rates. The London County Council desires to take over the water supply, but bills have so far failed because of disagreement as to compensation. The Board of Works, and now the County Council, has safeguarded the interest of the public; no addition to share capital has been allowed since 1878, and the interest on debentures has since 1894 been limited to a rate that in the judgment of the Governor of the Bank of England would secure issue at par. The companies cannot pay more than 10 per cent. dividend except to make up lower previous dividends; the actual rate has ranged from 5 to 12½ per cent., and the price of the stock ranges from 150 to 420, reducing the actual return to from 2⅞ to 3½ per cent. on present investment value. Any surplus must be invested as a reserve fund in the hands of the City Chamberlain.

London is supplied with gas from three private companies, under close government regulation. The price is from 2s. 5d. to 3s. 6d. (58 to 84 cents) per thousand cubic feet of gas giving 15 candle power in a five-foot burner. Meters are tested by

[1]Die Berliner Elektrizitäts Werke bis Ende 1896, von G. Kemman (Springer, 1897); Die öffentliche Beleuchtung von Berlin, von Dr. H. Lux (Fischer, 1896); Berichte Berliner Elektrizitäts Werke; Elek. Zeitg., 1 Juli, 1897; Tech. Führer von Budapest, von A. E. Illes (Patria, 1896).

County Council officials at a charge of from 6 pence (12 cents) to 3 shillings (72 cents) or more, for which the gas company pays if the meter is inaccurate and the consumer if it is accurate.

London has ten electric lighting companies and four vestry municipal plants, occupying under "Provisional Order" charters, specified districts of London, in some cases exclusive, in other cases with two companies in competition. The price is limited by the Board of Trade to a maximum of 8 pence (16 cents) per unit. In practice the base rate of the companies varies from 8 pence (16 cents) to 6 pence (12 cents), not including lamps, with a sliding scale reducing the price as low as 4 pence for motive power, or in one case 3 pence if used during the daytime alone. The share and loan capital together of the ten companies exceeds £4,500,000. The sales in 1896 exceeded 18,000,000 kilowatt hours, and the returns £450,000, making an average rate of practically 6 pence (12 cents) per unit, or 6-10c. per 16 candle power lamp hour, which does not include lamps. The most successful, though not the largest of the London companies, received in 1896 an average price of 5.63 pence (11 cents), and its operating expenses were 3.34 pence (6¾ cents). Of the municipal plants only that in the parish of St. Pancras is comparable; its investment is about £109,000; its output in 1896 was 850,000 units; its average price 5.34 pence, and its average cost 4 pence. The other three plants in the parishes of Hampstead, Islington and Shoreditch, are small or new. The last, however, has been designed by enterprising private contractors, who have installed a "destructor" plant, utilizing the refuse from the streets for fuel, and a thermal storage apparatus of the Druitt-Halpin method. This plant was put in operation only in 1897, and no figures are yet available. It promises, however, to present one of the most favorable examples of municipal supply in the world. In the small Hampstead municipal plant the average price was 5.54 pence, and the expenditure of 7.38 pence, so that the ratepayers paid a third of the actual cost. The Crystal Palace private company also showed a loss.

The new County Council thoroughfares in London are supplied with several miles of subway tunnels, accessible from various points and providing access through manholes to the sewers as well as facilities for all kinds of subway service, including water mains, gas pipes, electric conduits and a hydraulic service for elevators and motor purposes at over 1,000 pounds pressure. From these subways alcove connections are made on either side between each pair of buildings.

MISCELLANEOUS

The Relations Between the Customer, Consulting Engineer, and the Electrical Manufacturer.[1]

BY S. DANA GREENE.

THE subject which I have chosen for this paper is an eminently practical one, and I shall endeavor in my remarks to call attention to certain causes of friction which at present exist between the parties in interest, and to suggest certain remedies which may serve to bring about a better understanding and to lessen this friction, which is, in my opinion, entirely unnecessary.

In order to discuss intelligently present conditions, it is advisable to trace briefly the development of the electrical business, and to do this one need hardly go back more than a dozen years. At that time electric lighting was still an experiment (from the commercial standpoint), electric railroading had not begun and electric power transmission was discussed as one of the possibilities of the future. Very few of our institutions of learning had established separate electrical courses, and such a thing as a consulting electrical engineer hardly existed in this country. The few men who had some theoretical knowledge were eagerly caught up by the manufacturing companies, who had difficulty to find men capable of solving the many pressing practical problems with which they were confronted, when they began to sell electric machinery. Thus the development of a practical generator and incandescent lamp immediately created a demand for suitable conductors and materials for outside and inside wiring, safety devices, etc., as well as close regulating engines, proper station appliances and many other things which are to-day regarded as "standards" in the business. It was less than a dozen years ago that the first fireproof switchboard was installed, in the Broadway Theatre. The specifications were drawn by a consulting engineer—a naval officer by the way—calling for a fireproof structure, and the manufacturer no doubt accepted the order thinking that he could use what had always been used before, viz., a wooden framework. In this he was mistaken, however, and after a year's wrangling a slate board was installed, much to the manufacturer's disgust, and at great expense to him. It is hardly necessary to say that this form of switchboard became standard immediately, and several years after, the manufacturer, happening to meet the naval officer, said to him, "Someone was a d——d fool about that switchboard and you were not the man." I well remember when I left the navy to join the Sprague Company in June, 1887, I found that the technical force of the company consisted of Mr. Sprague, an ex-naval officer, and Lieut. Crosby, who had just left the army. Upon explaining to the former how modest was my store of knowledge on the subject of "electric street railways," he at once reassured me by saying that we were all in about the same boat, and that there was a fine opportunity to learn! My opportunity came sooner than I expected when, about July 1, I was charged with the execution of a contract for the equipment of a 40-car road in Richmond, Va., which, under the terms of the contract, was to be in full and complete operation on the first of the following October.

Doubtless most of those present to-night can recall the remarkable growth of electric lighting and railway work, during the next five years, from 1887 to 1892, a growth that can fairly be called tropical. Plants sprang up in nearly every city and town in the country, and manufacturers sprang up with equal rapidity. There seemed to be unlimited money ready to invest in electrical enterprises, and the anticipated profits were such as to make the old established manufacturing industries seem very poor investments. During this period, which may be called the "forced expansion period," purchasers usually had to take what they could get and consulting engineers were few and far between. Specifications for apparatus or installations, when there were any, were generally prepared by the manufacturer, and the purchaser rarely knew whether they had been fulfilled or not. By the close of this period, however, the colleges and technical schools began to turn out men who had taken special courses in electricity and who naturally looked for a chance to make an honest living. The first great demand of the manufacturing companies for technical assistants having been satisfied, many of these young men found their way into local operating companies, or else established themselves as consulting or contracting engineers, in which positions they found plenty of work; for by this time the imperfections in the earlier installations and types of apparatus had become plainly evident, to the purchaser, as well as to the manufacturer, and there was a general demand for better workmanship and more rigid requirements in installation. It may be here noted that much of the "anticipated profit" of the business, both of the operating and manufacturing companies, was spent subsequently in making good these early defects; and while the business as a whole profited largely by this reconstruction process, it naturally dampened the enthusiasm of the early investors.

In 1893 came the panic, and for the past four years there has been a wonderful record of savings and economies, both in electrical manufacturing and operating companies, as well as a great improvement in quality of product. It has been, in fact, the "economic and reconstruction period." The operating companies have learned that they, too, are manufacturers of a product, electricity; and as these hard times have forced down the price of their product, they, like the manufacturers of apparatus, have to keep their heads above water and their companies out of receivers' hands by the introduction of more economical and improved methods of manufacture and of administration. During the past year there has been a marked improvement in the electrical business; it is to be hoped that this improvement is permanent, and that the past four years of retrenchment and economy have paved the way for a normal and steady growth on conservative lines. In other words, for a period of "natural expansion." The business to-day is on

[1]A paper read before the New York Electrical Society, at the College of the City of New York, Jan. 12, 1898.

much the same basis as in other industries, where prices are close, competition keen, and where a better article is furnished for less money than ever before.

The manufacturers of apparatus and the manufacturers of current are dependent upon each other to a large extent, and their relations should be close and friendly. The consulting engineer, as in other engineering trades, is a necessary and proper connecting link between the two, and I can say frankly that I believe he has a proper and permanent field of usefulness. Broadly speaking, his function is to see that his client who buys apparatus and installs it, selects first that system best suited to his particular local conditions, and then, in purchasing, secures the best (not necessarily the most) for his money. It is equally the duty of the consulting engineer to learn what the manufacturer can reasonably be called upon to make, to consult with him freely and to obtain the benefit of his experience; to give him credit for work well done, and to insist that bad work shall be promptly corrected. Many consulting engineers, especially those who have recently commenced practice, seem to think that it is improper for them to consult with the manufacturer, or to examine his plant, or to ask him for information or advice. Their idea seems to be that, by so doing, they may be accused of partiality or undue bias, or with lack of proper care for the interests of the purchaser; or they may feel that it is derogatory to their own dignity as independent engineers. The inevitable result is that specifications often contain provisions which are a source of annoyance and expense to the manufacturer and purchaser alike, and which have no compensating advantages, from either the engineering or commercial standpoint. In fact, some of these provisions are impossible or impracticable of fulfillment; and in such cases the honest manufacturer who wishes to meet the specifications and guarantees required, finds himself forced to ask the engineer or the purchaser (sometimes both) to modify them.. This is a proceeding which is always difficult and delicate to undertake, and often results in friction and trouble for all concerned. I am satisfied that if every consulting engineer would take advantage of opportunities as they occur, to visit manufacturing establishments, see the work there in progress and confer with the engineers, he would find himself well repaid for the visit, and his own work and practice benefitted thereby. I am equally satisfied that no reputable manufacturing establishment would refuse admittance, but on the contrary would welcome such visits as beneficial to both parties. The day of mysterious methods of manufacture, carried on behind closed doors, is passed in the electrical business, and I appeal with confidence for an endorsement of the opinions just expressed, to those consulting engineers who have already tried the plan suggested. I have said that I thought the engineer would find himself repaid by such visits. I think, also, that he will find himself in a better position to advise his client intelligently. A purchaser usually knows little or nothing of the relative technical merits of apparatus, and his final decision is governed largely by price and by paper statements and guarantees, which may mean much or little. The consulting engineer who has seen the apparatus in process of manufacture can advise not only as to whether the various bids comply with the specifications, but also what make or makes of apparatus are, from their design, construction and factory inspection and test, most likely to give the least trouble and expense in continuous service.

Some engineers seem to measure their value to the purchaser by the length of their specifications, and some of these formidable documents strike terror to the heart of a busy man confronted by a desk full of mail. The specifications not only specify what the conditions of service are, what apparatus is required and what tests shall be applied to it for acceptance, all of which are quite proper; but also how it shall be built, which is another matter. The electrical manufacturers of this country following the admirable precedent which has given American manufactured products (particularly machinery) a world wide reputation, have endeavored to establish standard lines of apparatus, whenever the permanency of type and the size of the demand warrant it. This practice not only tends to reduce cost (and with it price), but also enables the purchaser to secure quickly and at a minimum of expense, duplicate parts which are really duplicates and which can be fitted without the aid of a skilled mechanic. It is the American system of standard lines of machinery and interchangeability of parts, which has stood the test of time and which holds its own against all competitors. This system, however, is possible only where the same article is manufactured in quantity, since the expense of designs, drawings and patterns, special tools, jigs, dies, etc., is prohibitive unless spread over a large production. On the other hand, if special apparatus is required, it means a relatively large expense for these items which cannot be charged to a standard product, and which thus constitute a handicap both to the manufacturer and the purchaser. A machine is "standardized" only after long experience, both in manufacture and service, and other manufacturers (the builders of engines, trucks, etc.) as well as the users, are invariably consulted before such standardization. It would appear to be to the interest of both seller and buyer to use such standard machines wherever and whenever possible; and yet it seems to be a fact that the demand for special machines is increasing, rather than decreasing, as apparatus becomes more generally standardized. To prove this I can cite the experience for the past year of one manufacturing company, with which I am familiar. During this period, the designing engineers were called upon for estimates on special apparatus, as follows:

Direct current:
Number of estimates 300
Number of kw. of app. involved.................. 31,000
Alternating current:
Number of estimates 300
Number of kw. of app. involved..................131,200

These estimates were all embodied in formal propositions; besides these were between two and three times as many preliminary estimates required to answer inquiries of customers, which the engineers had to prepare.

This was in addition to their regular work on standard lines of apparatus, of which there are over thirty. Some of this work was undoubtedly due to new developments in the business and to new methods and inventions, a condition which, although unfortunate from the manufacturing standpoint, must exist for many years to come; but a great deal of it was also due to the fact that specifications call for special apparatus, or methods of construction, where standard apparatus and methods would do equally well. This experience I find is common among electrical manufacturers, and I attribute it largely to lack of touch between the manufacturer and the engineer drawing the specifications, whether he be regularly employed by the purchaser, or retained in an advisory capacity. Let the engineer see more of the manufacturer and his work and let him hold the latter responsible for results, as determined by proper tests, leaving the details of construction where they belong, in the manufacturer's hands.

This brings us to another phase of the subject, viz.: the tests and guarantees prescribed by specifications. Omitting from consideration matters which as already stated belong properly to the designer and builder, such as current densities in the windings or in brushes, methods of insulation, kinds of material, etc., etc., the tests necessary to determine a machine's quality (and hence its value to the purchaser) are few in number and can be enumerated under the headings of efficiency, heating, regulation, sparking and insulation. If the requirements under these five headings were formulated under some general rules, and if the methods of tests to determine results were uniform, the work of the consulting engineer and the manufacturer would be vastly lessened. Such, unfortunately, is not the case, and specifications on these points vary widely both as to requirements and as to the method of test. It seems practically impossible for the various manufacturers and consulting engineers to standardize these requirements and tests by any concerted action, and the only other solution of the difficulty is for some scientific, non-partisan organization to undertake the work. The American Institute of Electrical Engineers is just such a body, and it would render a great service to the entire electrical business if it would consider the matter. Without attempting in any way to suggest what action it should take, it seems proper to call attention to some of the points which most frequently give rise to misunderstandings and disputes.

1. Efficiency.—The proper distinction between electrical and commercial efficiency is not made. The latter is what interests the purchaser and it should always be specified. A clear statement of what losses must be included to determine it, and also a general statement of what constitute reasonable

and proper commercial efficiencies in well designed machines would be of great service. Such a statement should show the necessary difference between carbon and copper brushes, and between the voltages most commonly used in direct current work, viz.: 125, 250 and 500 volts, as well as between machines of various sizes. The formulation of such information on alternators is more difficult, but all manufacturers have certain standard lines of these machines and it is quite possible to make some intelligent general rules.

Electrical manufacturers are sometimes required to guarantee the combined efficiency of generator and engine (or other prime mover). This is clearly unfair and shifts the direct responsibility of guarantee from the maker of the prime mover, where it properly belongs.

2. Heating.—For all ordinary conditions of service, the safe heating limits for continuous full load operation can be determined with a fair degree of accuracy. The commutator heats more than any other part of the machine, particularly with carbon brushes, a fact which is often ignored. Sometimes the heating is measured by thermometer, sometimes by increase in resistance. There should be one uniform method followed. Overload guarantees (ranging from 25 per cent. to 100 per cent.) are sometimes required for a period within which the ultimate temperature of the machine is reached, and the necessary capacity of the machine is thus increased as certainly as though a larger machine were specified. It would seem that the time duration of overload tests should bear some relation to service conditions. If the service requires a 50 per cent. overload for eight hours or more, a larger machine is evidently necessary.

3. Regulation.—Specifications frequently call for a straight line compounding curve, a condition which is practically impossible until we discover a magnetic material which has a straight line saturation curve. Another common requirement in the case of lighting generators, is that a drop of, say, 2 per cent. in speed shall not affect the electromotive force more than 2 volts, which is also an impossible condition, even with a separately excited generator. A reasonable margin in either case, having due regard to the service for which the generator is intended, should always be allowed.

4. Sparking.—Modern design, and the use of carbon brushes, have greatly reduced the trouble from sparking, but machines are sometimes called upon to stand excessive overloads without sparking, which can be accomplished only by using a larger machine or by a distortion of design, which is bad practice. Any good machine, with carbon brushes, should be able to stand a variation from no load to full load without movement of brushes and without noticeable sparking; it should also stand a reasonable overload, say, 25 per cent., without injurious sparking.

5. Insulation.—This is a cause of frequent trouble and annoyance. The common practice is to specify an insulation resistance of so many megohms, regardless of the size of the machine and the voltage and conditions of service. Considering the fact that this resistance varies inversely as the area of surface to be insulated, and considering the enormous variations in size, shape, voltage and service requirements of different machines, it is evident that such a test is impracticable and means little or nothing. Insulation resistance is largely a question of dryness, and if an armature be baked for a sufficient length of time, almost any resistance within reason can be obtained. I have known a large 400 kilowatt lighting armature to measure a megohm resistance, as required by specifications, after several days' baking (which, by the way, permanently injures the structural strength of the insulating material) and yet it showed practically no resistance when it reached its destination, because it had been in the rain and dampness for a week or more, and the large surface naturally afforded an excellent lodging place for moisture. A day's run in a weak field, with the armature short circuited, quickly brought the insulation up again.

The only proper way to insure good insulation, with reference both to the material used and the method of construction employed, is by a high potential test applied when the machine is reasonably dry. This test should be intelligently gauged by the voltage of the machine and the service required. Thus a high potential test of 1,000 volts is ample to detect any insulation weakness in a 125-volt lighting generator, while a 5,000-volt test is ample for a 1,000-volt alternator, allowing proper factor of safety in each case. Recent careful investigations have developed the fact that the only correct way in which to determine the proper high potential test for any given machine is to consider jointly the time duration of test, the current frequency and the voltage of machine. As the latter rises, the margin between it and the test voltage necessarily decreases on account of the liability to permanent injury of the insulation when subjected to excessive voltages. Because 5,000 volts is found to be a proper test voltage for a 1,000-volt machine, it by no means follows that 50,000-volts is proper for a 10,000-volt machine, or that the apparent factor of safety should be the same as the voltage rises. There should be a careful formulation of proper high potential tests for different classes of apparatus, based upon scientific investigation and tests, and it is believed that it would not be a matter of any great difficulty to formulate such a schedule.

It is earnestly to be hoped that the Institute will consider that these questions come properly within its sphere of action, and that it will take action in a matter of so much moment to all concerned. It should be remembered that where special conditions are imposed which lead to distortion of design or to the manufacture of special apparatus, the purchaser, no less than the manufacturer, is bound to suffer, and it is the purchaser who pays the bills, directly or indirectly. If the purchaser finds himself involved in unexpected expenditures, the consulting engineer, too, comes in for his share of blame and dissatisfaction.

We come finally to the commercial requirements which have gradually found their way into specifications, and which are sometimes onerous and unfair. Perhaps the most important of these is the question of shipments. It is not uncommon for shipment to be specified by a certain date, under a forfeiture of so many dollars a day for each day's delay thereafter, and the award of the contract is often largely affected by such promises. The manufacturer starts the work in his shops, and if the time is short he is apt to work overtime. About the time the apparatus is ready for shipment, and without any previous warning, word comes to withhold shipment because the purchaser is not ready to receive it. There were recently fifteen carloads of apparatus lying in the yards of one of our manufacturing establishments, besides a number of large machines stored in the shipping and testing departments, which had been made on time contracts and held at the last moment by request of the customer. It is difficult for one not in this end of the business to realize the resulting demoralization throughout the shops, and it is a condition which could easily be remedied by the exercise of more foresight on the part of the purchaser and his engineer. In all cases where a penalty for delay in shipment is imposed, it is fair and reasonable to ask that a similar bonus should be awarded if shipment is made in advance of promised date, or if the purchaser is unable, through no fault of the manufacturer, to receive the apparatus on that date. It is sometimes required that the consulting engineer shall have full access to the shops at all times while the apparatus is in production. Such permission is impracticable if proper shop administration and discipline are maintained, and these visits should be made at certain specified stages of the work. It is, of course, always proper for an engineer to be present when the apparatus is finally tested.

A clause is commonly found in specifications providing that the consulting engineer shall be sole judge of the true intent and meaning of the specifications; and in case of any dispute thereunder his decision shall be final and binding. It is true that this clause is common in architects' and builders' contracts, but it is doubtful whether it could be enforced at law, in case of a dispute as to facts, and it certainly seems fair that in case of such a dispute, where the two parties honestly disagree, provision should be made for a third, disinterested party to act as arbiter.

While there are many contracts executed which involve one or more of the provisions (technical or commercial) mentioned above as liable to cause trouble, and where no trouble is experienced, due to the common sense and good judgment of both engineer and manufacturer, still the cases where trouble does arise are not infrequent, and the best specification is one so fair and so clear that no dispute or misunderstanding can arise, except with malicious intent, and which requires no arbiter to interpret its true intent and meaning.

In conclusion, let us hope that the customer, the consulting engineer and the manufacturer will, in the future, consult each other more freely and frankly, by personal interview or by cor-

respondence; and that all of them will unite in indorsing any intelligent attempt to standardize such tests and technical requirements of electrical apparatus as are matters of common usage in our daily business intercourse.

PERSONAL

Officers of the New Anchor Electric Co.

AMONG the most progressive of the younger electrical firms in New England is the Anchor Electric Company, of Boston, recently reorganized. The president of the company, Mr. George O. Proctor, is a native of Rockingham, Vt., where he first saw the light of day fifty years ago, being descended from the well known old New England family whose name he bears. He obtained his earliest education in Rockingham and later in the Chester, Vt., Academy. Farming and lumbering engrossed Mr. Proctor's attention until 1874, when he removed to Boston, and entered the grain business with his brother, under the firm name of Proctor Bros. This firm is still in existence and is among the largest hay and grain concerns in the vicinity of Boston. Mr. Proctor was honored by an election to the Massachusetts Legislature in 1892, being appointed on the Committee on Street Railways. He was re-elected in 1893, and placed on the Committee on Cities. Mr. Proctor is conspicuous in many social organizations and in Freemasonry circles, and is, besides, a director of the Somerville National Bank; president of the Lynn Trust Company, and a member of the Boston Chamber of Commerce. Mr. Proctor's long business and financial experience is everywhere noticeable in the company's management.

Mr. Guy H. Proctor, vice-president of the Anchor Electric Company, is the son of G. O. Proctor. His first business connection was with the Boston Rubber Company, in whose factory he mastered all the practical details of the rubber business. Thus qualified, he was placed in charge of that company's Chicago branch office, in which capacity he came in contact with the largest buyers of rubber goods in the country. Later Mr. Proctor accepted a position with the Conant Rubber Company, of Boston, whose selling agent he was prior to his connection with the Anchor Company. Besides an inherited business ability, Mr. Proctor has a considerable inventive faculty. Among other devices he designed, in connection with Capt. Samuel Abbott, of the Boston Protective Department, the protective cover now largely in use, and also numerous and valuable improvements in rubber goods. He brings to the Anchor Company the vigor and enthusiasm of youth, with a good business record behind him.

Mr. Norman Marshall, the company's treasurer, was born in Hampstead, N. H., in 1864. At sixteen he entered the office of an architect and civil engineer, thus following an early bent. Desirous of further perfecting himself in his chosen profession, he entered the Worcester Polytechnic Institute, from which he graduated as civil engineer in 1886. Immediately thereafter he entered the service of the Marr Construction Company, and took an active part in the erection of some of the earliest Edison stations in the country, finally becoming superintendent of the Marr Company. Among the stations erected under his supervision were those at Altoona, Pa.; Dayton and Columbus, O.; La Crosse, Wis.; Birmingham, Ala.; Fort Worth, Gainesville, Marshall and Houston, Tex. On his return from Texas, in 1889, Mr. Marshall took charge of the Marr Co.'s New England office, and later was appointed district engineer of the Westinghouse Company for New England. Desiring to engage in manufacturing, Mr. Marshall resigned his position in 1892, and organized the Iona Manufacturing Company, in Philadelphia, which in 1894 removed to Boston. From a plant employing a dozen men the business was increased until upon its merging with the Anchor Company, three years ago, it carried fifty employés on its factory pay rolls. Mr. Marshall's attention has heretofore been exclusively engrossed by the factory, but he now assumes, in addition, the duties of the treasurer and the company's financial management. We may add that the Anchor business has doubled since its organization three years ago.

George O. Proctor.

Guy H. Proctor.

Norman Marshall.

A Farewell Dinner to Messrs. Murray and Kimball.

It having been decided to remove the accounting department of Westinghouse, Church, Kerr & Co. from their New York to their Pittsburg office, and as this necessitated the change of residence from the East to the West of those who are in charge of this department, the engineering force of the company tendered a farewell dinner to Messrs. Warren L. Murray and Gardner W. Kimball on the eve of their departure on January 5. The affair was held in one of the private dining rooms of Mouquin's Fulton street restaurant, and was planned as a surprise for both guests, proving a most enjoyable affair in all respects. Plates were set for twenty-two, there being but a single absentee who was out of town. Mr. Walter C. Kerr, vice-president of the company, sat at the head of the table, with the two guests of the evening on either side, and Mr. Otis L. Williams, treasurer, at the other end. The bill of fare had been gotten up by several of the brightest members of the engineering force, who substituted mechanical for the usual French terms, to the amusement and in some cases to the consternation of their brother engineers. After the dinner had gotten well under way, Mr. Williams as toast master allowed no individual to escape, and there were in consequence twenty-one responses in regular order, besides several which were interpolated.

Mr. Kerr, in a few early remarks, expressed his pleasure at meeting the force in this form for the first time, and suggested that an annual dinner, or, perhaps, one more frequent, would not be a bad idea.

Mr. Murray has been in the employ of Westinghouse, Church, Kerr & Co. for fifteen years and Mr. Kimball nearly as long, and the New York office felt great regret at their leaving the East in the call of duty. A number of presentations were made to the two departing guests as tokens of esteem from their fellow-employés.

SOCIETY & CLUB NOTES

A Notable Meeting of the New York Electrical Society.

(Arrangements made with the Electrical Exhibition.)

ON January 12, the New York Electrical Society had its 184th meeting at the College of the City of New York, where most of its meetings this season will be held. President Dr. M. I. Pupin, of Columbia University, was in the chair. Mr. S. Dana Greene read a valuable and interesting paper on "The Relations Between the Customer, the Consulting Engineer and the Electric Manufacturer," printed elsewhere in this issue. The aim of Mr. Greene in this paper was to assist in bringing about that better understanding between these departments of the industry, on which so much of its welfare and prosperity depends.

Messrs. Max Osterberg, Gano S. Dunn, C. O. Mailloux, H. B. Coho and Drs. C. E. Emery and F. B. Crocker took part in the discussion.

The following resolution was duly presented and adopted:

Resolved, That in view of the excellent suggestions and recommendations on standardizing apparatus embodied in Mr. S. D. Greene's paper, the society hereby express its approval of efforts in that direction, and invites the American Institute of Electrical Engineers to consider some comprehensive plan for such standardization of American apparatus for electric light and power."

The new members elected were Otto Rothenstein, F. K. Vreeland, F. V. Henshaw, S. L. Griswold Knox, John Neilson, Putnam A. Bates, E. E. Higgins, Thomas A. Edison, Jr.

At the request of President Pupin the secretary, Mr. G. H. Guy, read the following announcement:

"For some time past the New York Electrical Society has been considering means for enlarging its scope of usefulness. and addressing a larger clientage among the citizens of New York, so as to bring the public into more intimate relations with the scientific aspect of all classes of electrical work. The proposition to hold an Electrical Exhibition at Madison Square Garden next May appeared to the Society to afford it the needed opportunity for putting itself prominently before the public, as the oldest electrical body in the country, and the recognized local Society, aiming by papers and discussions to diffuse the best electrical information.

"The Electrical Exhibition has very promptly and generously met the views of the New York Electrical Society, and has not only apportioned it space in the exhibition hall, for a booth and rendezvous for its members and friends, but has also placed at its disposal a contribution of funds for its educational work. This amount will be increased by a percentage of the admission receipts of the Exhibition, which is to be held 'under the auspices of the New York Electrical Society.' Members of the Society will be admitted to the Exhibition at half-price.

"It is believed, from what is already known, that this Exhibition will surpass anything of the kind ever done in this city, and will during the continuance of a month, not only do much to promote electrical interest, but enable the Society to reach a great many thousand people who should know of its work, and many hundreds who should unquestionably be in its membership.

"The Electrical Society is now organizing committees, and laying plans for a hearty and active co-operation in the work of the Exhibition, and looking, of course, to its own increase of membership and its fuller recognition as an authoritative, influential body.

"It is hoped and expected that this will mark the beginning of one of the most successful moves ever undertaken by the Society, and approving comments of friends and members encourage the Executive Committee to believe that they will be enthusiastically supported in the programme, the sole object of which is to increase and extend the Society's usefulness. The officers would, therefore, not only urge the members of the Society, individually and collectively, to assist in making the Exhibition as brilliant a success as possible, for the direct benefit that such success will confer on the Society, but wish also to impress on members the desirability of active co-operation with a view of increasing the membership (a membership which, now standing at 400, should be at least 1,000 before the year is out).

"It has been suggested that the Advisory Committee of the Society, representing its interests with the officers of the Exhibition, and for other exhibition purposes, should consist of the present officers and all the living ex-presidents, namely, Messrs, Francis W. Jones, John M. Pendleton, Dr. Francis B. Crocker, Joseph Wetzler, C. O. Mailloux, John W. Lieb, Jr., Dr. C. E. Emery, all of whom, it is understood, will gladly co-operate in this movement to develop work, to which they themselves have so actively contributed in past years."

The following resolution was put to the meeting and unanimously adopted: "Resolved, That having heard the report of the officers of the Society, in regard to the arrangement effected for co-operation with the approaching Electrical Exhibition in this city, the members hereby express their hearty approval and pledge themselves to active work, that shall make the most of this opportunity for promoting the interests of electricity and the welfare of the Society."

Henry Electrical Society.

The next meeting of the Henry Electrical Society will be held at Columbia University, Engineering Building, Room No. 302, on January 21, 1898, when Mr. D. R. Lovejoy will deliver a lecture on "The Induction Coil and High Potential Discharges." The lecture will treat of the practical design of the induction coil and will be illustrated by many experiments showing the various effects obtainable.

THE STOCK MARKET

A Strong Front to Business.

All the favorable business conditions noted of late remain in full force, and have had such an effect that the stock market has scored some remarkable advances, despite genuine uneasiness about the desperate situation in Cuba and Spain. Railroad earnings for December of leading roads, increased 13 per cent., while for the year 111 roads, with 100,000 miles of track, showed 7.5 per cent. increase over 1896. The Northwestern roads are already beginning to feel the Klondike spring rush, which bids fair to swamp them. Bank clearings for the first week in January gained 37 per cent. over the 1897 week, and 56 per cent. over 1894. Business failures were only 323 as compared with 478 in the first week of January, 1897. The iron market is conspicuously active and hopeful. Export trade continues large. Such indications speak for themselves as to the general revival, while the great easiness in the money market is creating an immense demand for investment bonds and good stocks.

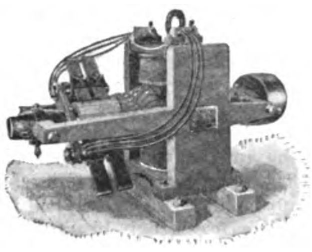
During the week, 39,918 shares of Western Union were sold around 90⅝ to 93⅝, and 17,060 of General Electric from 34 to 36. Bell Telephone is again very strong on the Boston market, and went up to 271 on sales of 665 shares.

Copper shows a rising tendency and was up to 11 cents last Friday. Steel rails are quiet at $18.

Kessler & Co., of New York City, offered last week at par $250,000 8 per cent. preferred stock of the Electric Vehicle Company, the issue having been underwritten by a guarantee syndicate. The authorized capital stock of the company is 50,000 shares of 8 per cent. non-cumulative preferred stock of $100 each, and 50,000 shares of common stock of $100 each. Six hundred shares of the preferred stock have already been issued, 2,500 shares are now offered, and the rest remain in the treasury of the company. The entire amount of $250,000 is to be expended for the benefit of the company, no part of it for patents, franchises or underwriters' commissions. Any dividends declared after the common stock shall have received 8 per cent, are to be divided prorata between the common stock and the preferred stock then outstanding. The subscribers will receive, in addition to each share of preferred stock, one share of full paid non-assessable common stock.

TRADE NOTES & NOVELTIES

The Mayer Motors and Lighting Dynamos.



We herewith illustrate the Mayer motors and dynamos, manufactured by Maxwell M. Mayer, Second avenue and 121st street, New York City. Although his plating dynamos have been in the market for over three years, and are well known as standard apparatus in that line, he has but recently gone into the manufacture of motors and lighting dynamos on any scale, although quite a few are running for a number of years. These machines are built on the same general lines as the plating dynamos, having a two pole iron-clad steel frame, cast in one piece with removable field coils. The armatures are of the slotted drum type, finely laminated to avoid heating. The commutators, which are of ample proportions, are made of tempered copper and insulated with sheet mica. The brushes are carbon in a self-feeding brush holder. The mechanical construction is of the very best. The shafts are large and run in self-oiling bearings. The machines are efficient, smooth running and noiseless, are made to last, and will no doubt meet with as much favor as the plating dynamos of the same make. They are built in four sizes from ½ to 4 k. w.

G. E. Improved Slow and Moderate Speed Belt Driven Generators.

The General Electric Company announces in a recent bulletin a line of new and improved slow and moderate speed belt-driven Generators, former types of which have proved so uniformly successful and efficient that they have come into very extensive use for both lighting and power purposes. The features of excellence which have tended to this result have all been retained, and the new line, somewhat different in appearance, embodies also all the improvements suggested by experience with the older types.

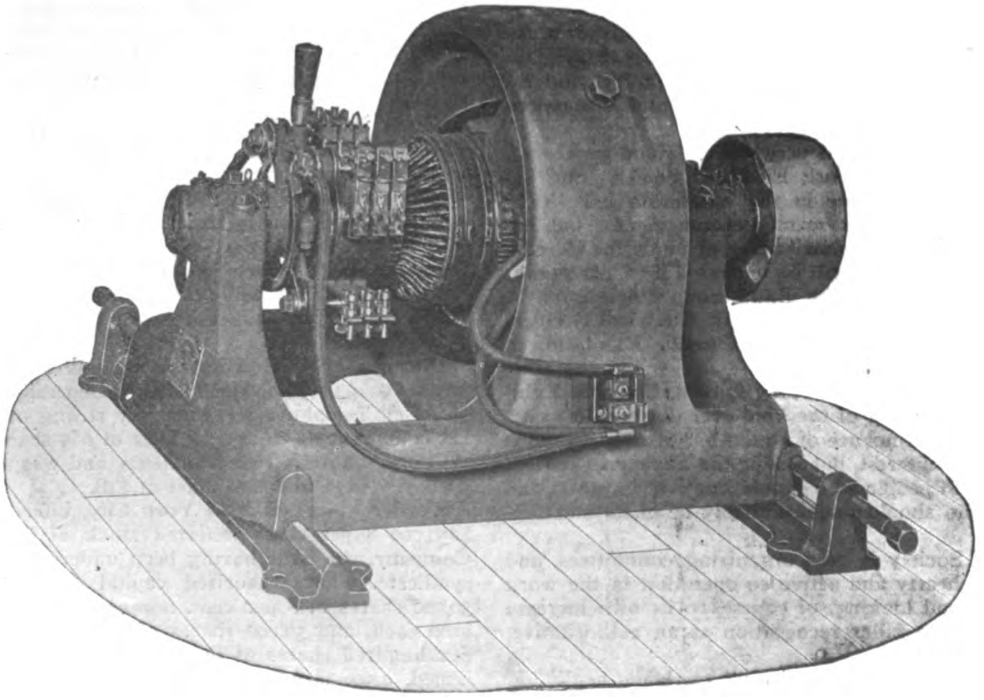
These machines are of the four-pole type. This construction allows of an extremely economical distribution of the magnetic material, while by shortening the magnetic circuits the exciting current is reduced and the efficiency increased. Reduction in speed implies increase of weight if the same output and efficiency are to be obtained, but low speeds with small weight per k. w. is possible in these machines owing to the economy in material effected by the adoption of the four-pole type. As the frames are of the highest quality of iron and the pole-pieces of special soft steel, these generators are lighter than even others of the same output but higher speed.

The floor space occupied is small; the frame is strong, rigid and graceful, and the dimensions are as small as possible consistent with stability. The mechanical construction of the bearings, shaft and oiling devices is such as to make the operation of the machines safe and easy, even to unskilled attendants. The comparatively low belt speed even in the smallest machines, results in less wear and tear of belts and bearings and noiseless running.

The pole-pieces are of special soft steel of the highest magnetic permeability. As they are detachable from the frame, the field coils are removable without disturbing the armature. The armature is built up of japanned sheet iron laminations assembled on a cast iron spider. Air ducts separate the laminations into groups and provide for thorough circulation through the windings, core and spider. The windings are copper wire coils, formed and insulated before assembling on the core.

These generators are sparkless and the brushes being of carbon require no shifting in changing from no load to overload. The only wear on the commutator is that due to friction, and the use of carbon brushes reduces this to a minimum. The rise in temperature in any part of the machine, except the commutator, will not exceed 45 degs. C., after continuous full load run of ten hours. The temperature rise of the commutator under the same conditions will not exceed 55 degs. C. All parts of the machine are interchangeable, and as the substitution of new parts requires no special skill or knowledge, any change can readily be made by the attendant.

The four-pole machines of the slow speed type are built in capacities from 6.5 k. w. to 75 k. w.; of the moderate speed type from 9 k. w. to 85 k. w. They are wound for 125, 250 and 500 volts. Many of them can be adapted for direct coupling to engines by mounting the machine on an extension of the engine bed, and connecting the armature to the engine shaft through a coupling.



NEW G. E. BELTED MEDIUM AND SLOW SPEED GENERATOR.

MR. F. M. LAUGHLIN, prominent in the Solar Carbon Co., of Pittsburg, was a busy visitor to New York this week.

Menominee 1898 Fans.

The Menominee, Mich., Elec. & Mechanical Co., manufacturers of general electrical supplies and fan motors, are making an entirely new design for their 1898 fans, in which beauty and high efficiency are taken into consideration, as well as the necessary and essential features of high efficiency and durability, which are just as fully kept in view as ever. Mr. Henry Tideman writes us that they have taken special pains this year to design a motor of high art and finish. Two dolphins of artistic design, resting on a fantastic base, hold the motor, which can be swung into any desired position. The effect is very charming and pleasing. All the machines are nickel plated in every part. The company will be glad to receive inquiries on the subject.

Recent Large Sales by Walker Co.

The Walker Company is now building at its Cleveland works a 1,600 k. w. direct connected generator for the Union Railway Company of New York City. This, with the two now being completed for the Brooklyn Heights Railroad Company, will make three of these 1,600 k. w. machines finished in as many months. In addition to this generator for the Union Railway Co., the Walker Company is building for them 40 double No. 4-A street railway equipments. The equipments are to be fitted with the new type "S" solenoid blow-out controller which has attracted so much attention. The current for these motors will be fed to the line from a Walker switchboard, now being built at New Haven.

The Metropolitan Street Railway, of Kansas City, which is now operated by a 1,600 k. w. Walker generator, is about to increase its plant by the addition of a generator of 1,200 k. w. capacity, and as a contrast to these immense machines it may be mentioned that the company is building a 25 k. w. lighting generator for Mr. J. J. Astor's new yacht.

The foreign shipments during the next few months will include 100 double 3 S street railway equipments, with 200 controllers, for Dresden, Germany; 6 double 3 N equipments with Type "S" controllers, and two double 3 N equipments.

Besides these railway motors and accessories there will be one 150 k. w. belted railway generator with its switchboard and a 75 k. w. belted booster for Japan, also with a switchboard.

This makes over 7,500 h. p. in street railway motors alone that are being built at the Cleveland works, to say nothing of the horse-power output in generators.

Warning Against a Sharper.

We have received a communication from Messrs. E. P. Roberts & Co., of Cleveland, requesting us to warn the engineering profession against a sharper operating under various aliases. His favorite method is to obtain money on bogus checks on a Utica, N. Y., bank, under the plea of having lost his pocketbook.

The man is described as apparently having considerable engineering information, and to be very shrewd and a good talker. He is about 45 years of age, 5 feet 8 inches or 5 feet 9 inches in height and probably weighs about 170 to 180 pounds. He is thick-set, carries himself erect, and has a quick, brisk walk. He has a dark complexion, dark hair, streaked with gray, a very square jaw and when last seen had a small pointed beard and moustace streaked with gray. A most prominent characteristic is a mark on his forehead resembling a burn or a bruise. The mark is approximately circular and about one inch in diameter.

SOUTHERN NOTES

MR. GEO. A. CRAGIN, agent of Washburn & Moen Mfg. Co., at 1015 Franklin avenue, Houston, Tex., favors us with a neat leather double pocket purse, in which money can be kept securely as long as his company's specialties are kept out of sight.

THOS. H. DALLETT & CO., Philadelphia, Pa., manufacturers of machine tools, have recently installed in the Brooklyn Navy Yard several of their portable electric drills. They manufacture also hand drills, electric portable planers, flexible couplings, etc.

WESTERN NOTES

MR. GEO. P. REX, Chicago, manager of the Columbia Incandescent Lamp Company, St. Louis, has recently closed some nice orders for lamps, among them being a contract for 15,000 Columbias for a large isolated plant in Chicago. The Columbia Lamp Company are working night and day to meet the increasing demand for their celebrated product.

THE OMAHA EXPOSITION is to have a special series of stamps, of a commemorative nature, issued for the occasion by the United States Post Office Department.

ALADDIN LIGHT COMPANY has been formed at Chicago by F. H. Fuller, A. P. Daniel and W. B. Reed, with a capital stock of $10,000 to make electrical goods.

McKINLOCK & CAMP, agents of the successors of the Metropolitan Electric Company, are handling the new Standard dry battery, which is manufactured by Wm. Roche, a pioneer dry battery maker. It is claimed to be superior to any dry battery on the market, and that a sample test will verify this statement.

WHEELER ELEC. AND MFG. CO., Dayton, O., whose dental machine we illustrated recently, have been incorporated under the laws of Ohio, for the manufacture of electrical goods and sundries. The officers of the company are: J. T. Dean, president; W. E. Wheeler, secretary and treasurer.

ACTIVITY IN SUPPLIES.—At this season of the year the amount of iron line material that enters into the business of a large supply house is indeed surprising. The Electric Appliance Company, Chicago, state that they are carrying a stock of these goods that will enable them to make prompt shipments of anything up to a carload, and yet their capacity has been taxed on these goods. The iron mills throughout the country have had a large amount of business this season, and it has at times been very difficult to get iron line material. The Electric Appliance Company, however, anticipated this condition and during the season have been able to keep their stock in shape so that all orders for this material could be shipped promptly. They state that their stock is still being kept up and that customers wanting iron construction material promptly from Chicago stock will not be disappointed.

AMERICAN RHEOSTAT CO., of Milwaukee, Wis., have opened quarters in Chicago, the George Cutter Co. being their agents, 1104 Rookery Building. They are enjoying an excellent demand for their specialties and expect to do even better throughout 1898.

RASTER CARBON RHEOSTAT COMPANY, of Chicago, have just started in business introducing their novel carbon rheostat which possesses many valuable and new features. These people are greatly gratified at the progress they have made in such a short time. They have already got behind in their orders.

MURRAY IRON WORKS, builders of Corliss engines, Burlington, Ia., have issued bonds for the purpose of making additions and improvements in their plant and have executed a trust deed to secure same. They have brought a libel suit for $20,000 damages against a credit agency for stating that the trust deed was to secure preferred creditors. The company say they have no debts and therefore no creditors to prefer.

PHILADELPHIA NOTES

OTTO GAS ENGINE WORKS, Philadelphia, report that they now have installed the two 120 h. p. gas engines for running electric lights at Sisterville, W. Va., and two 50 h. p. engines at Mannington, W. Va., for the same purpose. Business with them is excellent.

CHARLES WIRT.—We have received from Charles Wirt, Philadelphia, copy of pamphlet printed for a Japanese company, which is intended for distribution in the Flowery Kingdom.

MR. H. C. ROBERTS, formerly with Vallee Bros. & Com-

pany, notifies us that he will continue in the electrical trade, and that for the present he can be reached at the Franklin Machine Works, 32 North Fifth street, or 1019 Filbert street, Philadelphia, Pa.

NEW YORK NOTES.

MR. C. R. HUNTLEY, of the Buffalo General Electric Company, was a visitor to New York City last week, deeply interested in plans for power distribution in his city. He states that Messrs. Stillwell, Emmet and Townley have been in consultation there over various aspects of the question.

ROCHESTER ELECTRIC MANUFACTURING COMPANY, of Rochester, N. Y., has been formed with a capital stock of $50,000 to make the cut-out invented by Mr. L. W. Miller. The officers of the company are: President, Hon. W. E. Werner; vice-president, J. M. Kelly; secretary and treasurer, G. A. Brayer; general superintendent, L. W. Miller.

THE FERRACUTE MACHINE CO., Bridgeton, N. J., have just issued a large circular illustrating a number of their presses, and are mailing them to all parts of this country, and a large number abroad. The circular shows a cut of each kind of press, a number of which are especially adapted for electrical work. They will some months hence issue a new catalogue, which will probably be larger and handsomer than anything they have previously published.

MR. MINOR M. DAVIS, a well known electrician, and a tried official of the Postal Tel.-Cable Co., has been appointed traffic manager of that company, with headquarters at the New York main office, 253 Broadway. He is in receipt of hearty congratulations from a host of friends.

MR. A. A. THRESHER, Thresher Electric Co., of Dayton, O., was in New York City for several days past on important power transmission work.

ALBERT B. HERRICK, the consulting electrical engineer and expert, 150 Nassau street, American Society Building, formerly of Herrick & Burke, wishes to notify his clients who wish to consult him without previous appointment that he can always be found at his office on Mondays and Fridays each week; his out-of-town engagements making this necessary.

THORBURN REID, 120 Liberty street, has recently been retained by several large concerns as consulting electrical engineer. Mr. Reid makes a specialty of designing and supervising light and power plants, also designing and guaranteeing the performance of direct current dynamos and motors, alternators, transformers, rotary converters, synchronous alternating motors and induction motors, etc. Mr. Reid solicits correspondence on the subject.

NEW ENGLAND NOTES

THE WALLACE BARNES ESTATE, Bristol, Conn., have turned over the spring manufacturing business to the Wallace Barnes Company, who are now running it under the latter firm name. The management is the same, the manufacturing business being separated from the real estate. The firm report having added several thousand dollars' worth of new machinery to their fast-growing plant, and are now in a position to offer small springs and to do similar special work on order, for concerns in the electrical and allied fields. Inquiries and correspondence are welcomed in regard to goods in this line.

THE BERLIN IRON BRIDGE CO., of East Berlin, Conn., have a contract for a new drawbridge over the South Shrewsbury River, in Monmouth County, N. J. This bridge is to be 180 feet in length and 40 feet wide. The Berlin Company have the contract for both the substructure and superstructure.

W. H. BOWDLEAR & CO.—The insulating compound manufactured by W. H. Bowdlear & Co., 149 Pearl street, Boston, is meeting with good demand throughout the trade.

AMERICAN CIRCULAR LOOM CO., Boston, have issued a pretty colored picture of the old "Constitution" warship, now laid up at Kittery, Me. The picture is from an original by F. Wetherbee.

ADVERTISERS' HINTS

THE PRATT & WHITNEY CO., Hartford, Conn., advertise turret head machines in ten styles and forty-four sizes, with the latest improvements.

THE C. W. HUNT CO., 45 Broadway, N. Y., advertise coal handling machinery of every description, steam and electric hoisting engines, industrial railways, and the famous "Stevedore" manilla rope for transmission and hoisting.

ZIMDARS & HUNT, 127 Fifth avenue, New York, say their knife switches are built for business. Their catalogue and prices may be obtained by writing.

THE PENNSYLVANIA ELECTRIC CO., Marietta, Pa., are making low introductory prices on their telephones, the "Crescent," which they claim to be a strictly up-to-date instrument.

THE CENTRAL TELEPHONE & ELEC. CO., St. Louis, Mo., advertise their instruments as having the latest improvements.

THE UNITED CORRESPONDENCE SCHOOLS, 154 to 158 Fifth avenue, New York, offer a course in electrical engineering which costs the subscriber but seven cents per day.

THE MANHATTAN GENERAL CONSTRUCTION CO., 11 Broadway, N. Y., advertise the "Manhattan" electric projector, with any method of control and of any candle power.

THE HART & HEGEMAN MFG. CO., Hartford, Conn., have something to say regarding the style of contacts and the patent self-adjusting handle embodied in some styles of their switches.

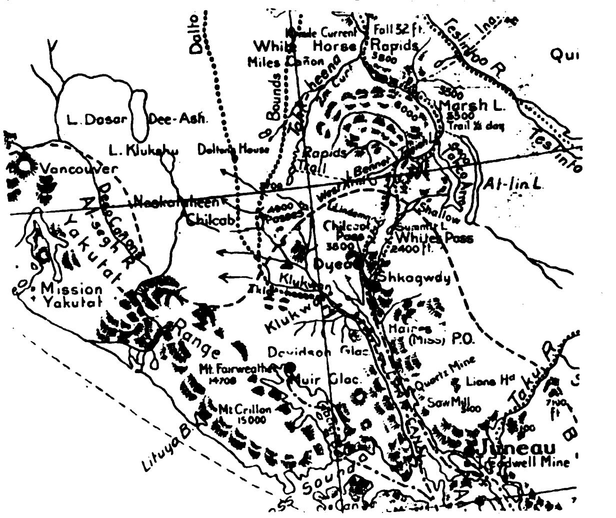
Vol. XXV. JANUARY 27, 1898. No. 508.

POWER TRANSMISSION

Operating Electrically A Klondike Wire Rope Tramway.

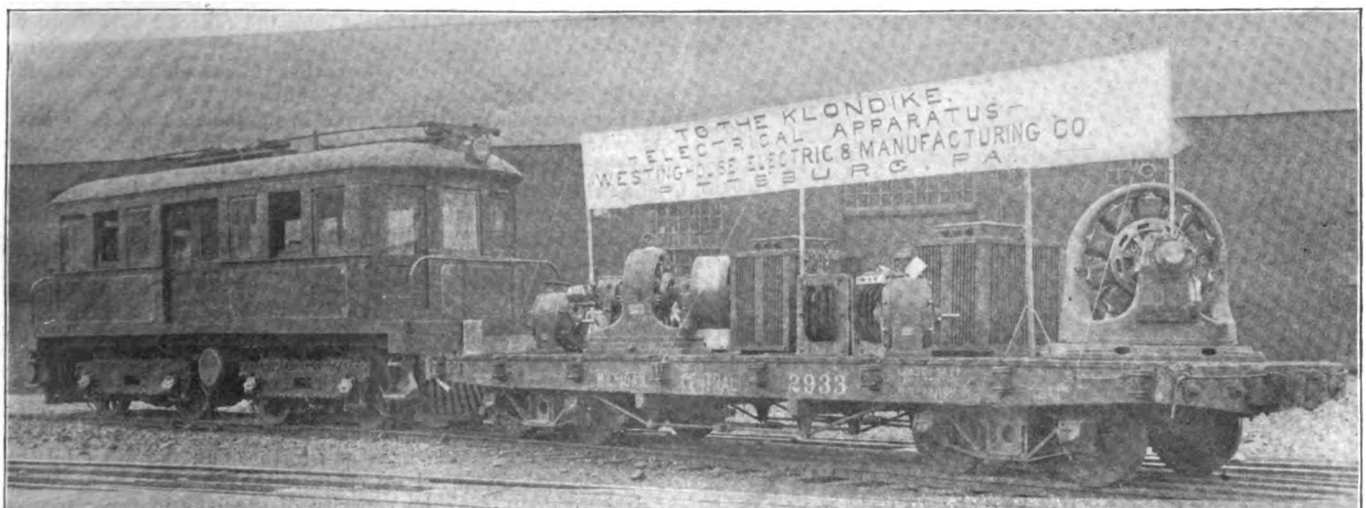
JUST how many people will pour into the Klondike region this spring, to rob its fastnesses of their hidden gold, it is hard to predict; but 100,000 is regarded by those who know as a very conservative estimate. Mr. C. O. Baker, Jr., the well known platinum merchant, who has just returned from the Pacific coast, informs us that he found cities like San Francisco and Seattle thrilling with excitement over the subject, and all kinds of preparations being made by hosts of people to move into the golden land just as soon as there was the slightest possibility of getting there with any degree of safety and certainty. How to get into the region is one of the great problems, even after one has landed on the bleak and inhospitable Alaska shore. There are four overland routes, as we understand it, from that point, and those by the Chilkoot and White Passes are the nearest to the headwaters of the Lewes River, where passengers and freight embark on the long waterway. For the present, the Chilkoot Pass remains the most popular of all the routes, as the all-water route through the mouth of the Yukon River is not much patronized; and there will be a great stream of Chilkoot travel this year.

But how to get over the terribly stiff and troublesome Chilkoot Pass has been a difficult question for everybody until recently, when it was decided to erect and operate a wire rope tramway for the purposes of transportation. In view of the tremendous interest in the subject all over the world, we are very glad to be able to show on this page an illustration of the electrical equipment that has just been shipped off to the Pass, for the Dyea Klondike Transportation Company, and which will soon be in full operation as the motive power for the two tramways along the line of travel. This plant has been built by the Westinghouse Electric and Manufacturing Company, of Pittsburg, and comprises one 45 k. w. two-phase alternator, with the accompanying exciters and switchboard; one 30 h. p. type "C" Westinghouse motor; one 15 h. p. type "C" motor; two 25 k. w. raising transformers and four 10 k. w. step-down transformers. Owing to the icebound nature of the region, steam will be the prime power, but as there is plenty of coal on the coast, the cost of operation should not be high. The distance of transmission is 13 miles. The line potential will be 5,000 volts, three-phase. One of the two tramways will be driven by the 30 h. p. motor, 12 miles from the generator, and the other one mile further by the 15 h. p. motor. In this way, the toil of the gold seekers will be very materially lessened, for one of the well established facts about the Klondike, outside its undoubted stores of gold, is that the Chilkoot



MAP SHOWING LOCATION OF CHILKOOT PASS, NEAR DYEA, ALASKA. (Elevation of Pass 3,500 Feet.)

is one of the toughest pieces of climbing to be found on the American continent. Hereafter, anybody willing to pay the fare, and a good many will be, can be swung along the electrically operated wire rope tramway, which is but one more graphic illustration of the flexibility and availability of electrical power methods.



CARLOAD OF APPARATUS TO OPERATE ELECTRICALLY WIRE ROPE TRAMWAY IN THE CHILKOOT PASS.
(Car Is Being Hauled Through the Westinghouse Yard, Brinton, Pa., by Electric Locomotive.)

The Great Northern Electric Grain Elevator at Buflalo N. Y.

BY O. E. DUNLAP.

THE Great Northern grain elevator built last year in Buffalo is one of the largest structures of its kind in the world, as well as the most novel in design and construction. To obtain great capacity for storage; to handle the grain going in and out with the greatest possible ease and economy was the study of the builders, and this they have accomplished in a manner that commands admiration. This success in construction is largely due to the full conception President J. J. Hill,

of the Great Northern Railroad, has of the needs and requirements of a great elevator, supplemented by the efficiency of D. A. Robinson, the builder.

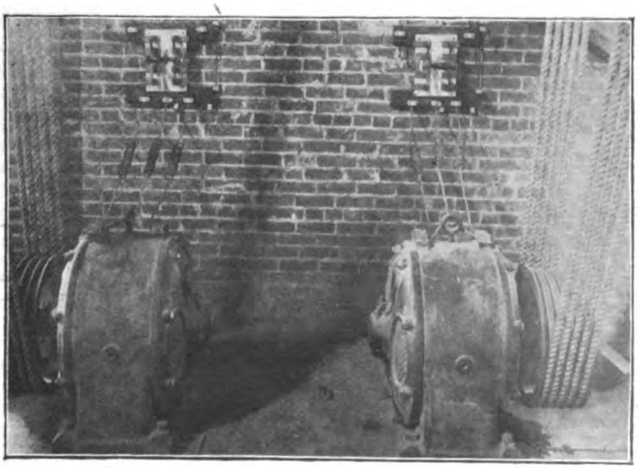
The elevator is situated on Ganson street and the Blackwell ship canal. From the outside its appearance is very like that of other elevators, its size and substantial appearance com-

GREAT NORTHERN STEEL TANK GRAIN ELEVATOR, BUFFALO, OPERATED BY ELECTRICITY.

manding attention. Its length is 396 feet, width 150 feet and height 177 feet. The interior construction is shown in one of the engravings appearing in our issue of August 19, 1897. The storage capacity of the elevator is provided for by large steel bins, cylindrical in form and having cone-shaped bottoms. In all there are 48 of these bins, together with 18 small shipping tanks. Thirty of the bins are 39 feet in diameter, 85 feet high, each having a capacity of 80,000 bushels. There are 18 bins 15½ feet in diameter, 85 feet high with a capacity of 18,000 bushels each. The 18 small shipping tanks are 9 feet 9 inches in diameter and 60 feet high. The combined storage capacity of the elevator is 3,000,000 bushels.

About 600 girders are used to support the bins, the height of the bottoms of the large bins from the ground floor being about 11 feet. The general girder plan is circular in shape after the ideas of Mr. Hill. The steel used in the construction of the bins is from ¼ to ½ inch in thickness, and in their construction about 6,000 tons were used.

The power used in operating the elevator is electricity transmitted from Niagara Falls. The elevator is fitted with 10 inside legs, and each of these is driven by a 50 h. p. motor by means of a rope drive. Each leg is 177 feet high and carries two rows of buckets capable of handling 15,000 bushels of grain an hour. In addition to this each leg has its separate



MOTORS DRIVING CONVEYOR BELTS.

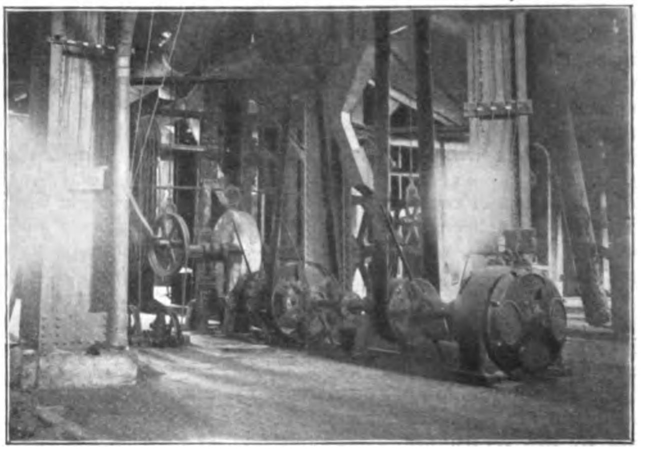
scales and hopper, which weigh the grain before it is stored. All the 50 h. p. motors are placed in a row on the south side of the floor over the bins, and in the line with them there is a motor of 100 h. p. which operates fans and dust collectors. There are also 10 double-jointed distributing spouts connected with the bins and scales, and two similar spouts are used to carry the grain from the cleaners to the bins.

The conveyor belts run along the north side of the building over the bins. They are two in number, each 60 inches wide and 740 feet long, and are said to be the largest belts of the kind in the world, having a capacity of about 40,000 bushels per hour each. They are provided with Robinson's patent reversible self-moving trippers, and are run by two 20 h. p. motors which stand at the west end of the floor. These motors are reversible. On the various floors of the cupola are located the elevator heads, the gearing for reducing speed, 27 steel garners each with a capacity of 1,500 bushels, 10 steel hopper scales, each of the same capacity as the garners.

In looking along the ground floor one sees the great cone-shaped bottoms of the big bins overhead. This floor is paved with brick, and along the north side runs a railroad track slightly depressed. At the west end of the building a spiral stairway leads to the upper floors, while at the east end there is an electric elevator which runs to the scale floor. This elevator is provided with a 10 h. p. motor. The floor is so arranged and provided with openings that it can be flushed at will, the drainage being into the canal at the side.

In the northwest corner a vault-like room is provided for the switchboards, transformers, etc., and in the southwest corner a similar room is devoted to the office of Superintendent John Lane, who is one of the best posted and capable elevator men in the country.

In the center of the ground floor stands a 50 h. p. motor devoted to operating dust collector fans, and operating the



50 H. P. MOTOR AND MACHINERY IN THE CENTER OF GROUND FLOOR.

cable under the building whereby the company are enabled to do their own car switching from the railroad yards and at the side of the elevator by electrical power. This motor also runs the cable by which the marine towers on the canal side of the building are moved back and forth.

These marine towers are three in number. They each have 32 wheels and are operated on two railroad tracks of the standard gauge laid on the dock along the Blackwell canal. The width of dock between the elevator and the canal on which the towers stand is 24 feet. The dock is built of stone, and the towers of steel. Each tower is provided with a marine leg capable of elevating 20,000 bushels of grain an hour, thus the three towers can elevate 60,000 bushels an hour, or 600,000 bushels in a day of 10 hours.

In each tower there is a 100 h. p. electric motor, the switches and starters being mounted over them. Trolley shoes are used, and the current for operating these motors is obtained from three trolley wires which run along the outside of the elevator for its entire length at a height of about 40 feet from the dock. The towers are moved back and forth along the dock by the same method employed on cable railways.

It is evident from the capacity of the legs in these towers that the unloading capacity of the elevator is excellent, but its shipping facilities are none the less so. Double tracks run along the building under a protective awning of steel on the north side, and on either of these tracks nine cars can be loaded at a time, or about 400 cars a day. At the west end a slip provides room for canal boats, by which 100,000 bushels can be shipped daily. Added to this, 200,000 bushels can be shipped daily by vessels on the Blackwell canal side.

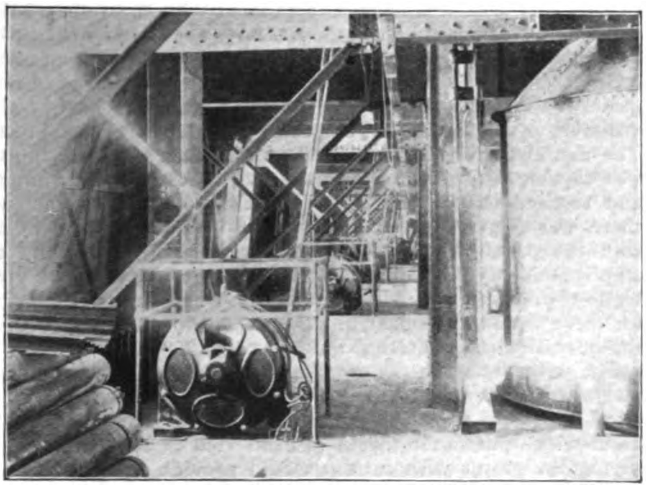
The Cataract Power and Conduit Company are the distributing agents for Niagara power in Buffalo. The power they supply to the Great Northern elevator is transmitted over 30 miles from the point of generation to the point of application. It passes over the pole line to Buffalo at 11,000 volts, and is conducted throughout the city underground to a new transformer station on Ohio street, where the voltage is reduced to about 2,200, and it is at this voltage that it is supplied to the Great Northern Elevator Company.

At the elevator it is passed through two transformers, each of about 600 h. p., and the voltage is still further reduced to 440 volts, at which it is used. The current comes to the elevator at three-phase and is used as two-phase.

Four cables, each of 1,000,000 circular mils, connect the transformers with the main switchboard, which is of white marble and has nine panels. Upon each of these panels are mounted the starting and controlling devices for two of the motors.

The motors and electrical equipment were supplied by the Westinghouse Electric and Manufacturing Company, of Pittsburg, Pa. They are of the induction type, 6-pole, 440 volts, and make 500 revolutions per minute. With the exception of the marine tower motors, all the motors are started and stopped from the main switchboard. The motors being sparkless, there is no danger of their igniting the grain dust, which is an important factor of danger about a grain elevator.

The wiring of the building is of open work construction with single wire cleat supports, flexible cable, rubber covered. There are 420 lights in the building, and they are run on the two-phase system. All of them are controlled from the light



LINE OF 50 H. P. MOTORS USED TO DRIVE THE INSIDE LEGS OF THE ELEVATOR.

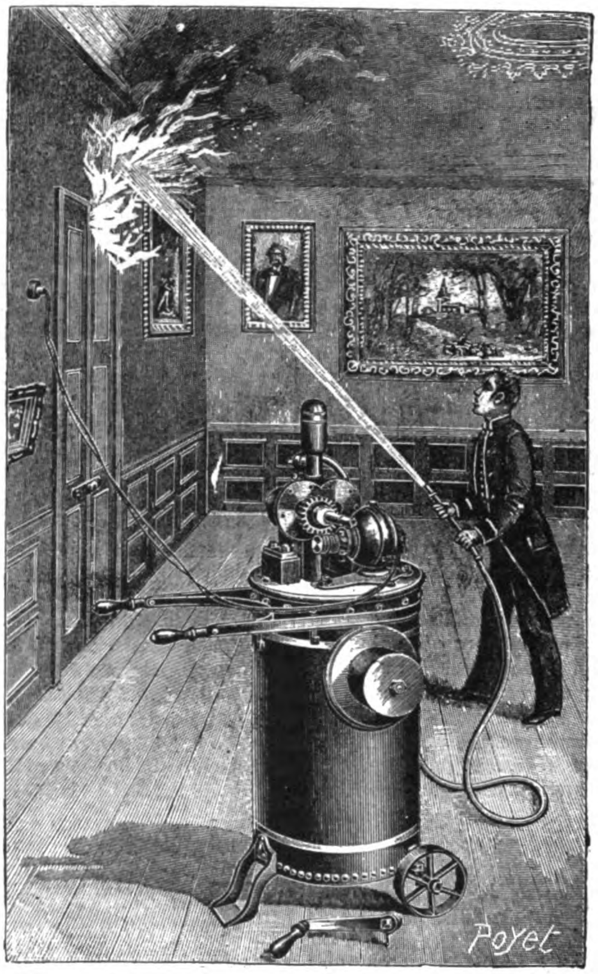
board in the transformer room and by distribution boxes for each 10 lights. A system of call bells and telephones has been established throughout the elevator, and all has worked with complete satisfaction.

The owners of the building are the Great Northern Elevator Company, of which W. C. Farrington, of Buffalo, is president and general manager, and Frederick W. Bobbett, of New York, secretary-treasurer. The plant cost about $500,000, which is but a small part of the Great Northern's interests in Buffalo. It will be operated in connection with the Great Northern Railroad and the Great Northern Steamship Company, the boats of which latter company are the finest on the great chain of lakes. To the business ability of President Hill, of the Great Northern Railroad Company, the world is indebted for this modern, up-to-date consumer of the power of the great cataract.

COLUMBUS, MISS.—The Electric Lighting Co. of Columbus, Miss., write us: "We hand you herewith our check for $4.50 for another year's subscription to The Engineer and for a want ad. We are now installing duplicate machinery—a 100 h. p. Skinner engine and boiler, a 50 k. w. Stanley alternator, switchboard equipment, etc."

The Merriweather Portable Electric Fire Extinguisher.

WE illustrate herewith a very ingenious use of the electric motor for the purposes of a portable fire extinguisher in houses, hotels, factories, etc. It is the design of Merriweather & Son, of Greenwich, England. As will be seen, an



PORTABLE ELECTRIC FIRE EXTINGUISHER FOR INTERIORS.

iron-clad motor of the Lundell type is mounted on top of a small rolling tank which will hold about 120 liters of water or extinguishing chemical, and it can be plugged into any floor or wall receptacle at a second's warning; when the pump at once begins work and directs a sharp, strong stream against the incipient blaze. The motor need be of but small size, and the capacity of the tank also need not be considerable as it can obviously be replenished or else the fire will have attained proportions beyond the ability of any small house apparatus.

Prices for Street Arcs in New York City.

The New York Gas Commission met recently to decide on the city lighting for 1898. The Brush Company was awarded 975 arc lights at 40 cents a night each. The Mount Morris Company got 630 arc lights at 40 cents a night each and 194 arc lights at 45 cents a night each. The Manhattan Company got 840 arc lights at 40 cents a night each and 10 lights at 50 cents a night each, 100 incandescent lights at $1.87½ a month each and 24 incandescent lights at $2.50 a month each. The Harlem Company got 66 arc lights at 40 cents a night each and 19 arc lights at 50 cents a night each. The North River Company got 1,052 arc lights at 40 cents a night each. The Edison Company got 360 double lamps at 50 cents a night each and 524 arc lights at 40 cents a night each.

PROF. LENARD, of Heidelberg, who first discovered the cathode rays, has received from the French Academy of Sciences its prize of 10,000 francs.

ELECTRIC LIGHTING

Circuit Breakers and Their Use in Power Transmission.

BY W. H. TAPLEY.

Chief Electrician U. S. Government Printing Office.

When the application of individual electric motors to driving machinery became firmly established in the manufacturing world, and was conceded to be a more economical method of power transmission than belting with long lines of shafting, second only to the motor, and how properly to connect it to the machine which it was to operate, was the subject of suitable protection both to motor and machine.

The first thing that suggested itself, and naturally, was to protect the motor in the same way as lighting circuits, namely, to introduce a suitable fuse. This was done, and where motors were belted, the results attending overloads were rather of an annoying and aggravating nature than anything which could really be called serious; yet when gearing and the direct application of armature to the main driving shaft of a machine began to supersede the belt, it was only a short time before the fact that a fuse was not an adequate protection became forcibly impressed upon the advocates of electrical power transmission.

As the art advanced, the thing to which the electrical engineer would turn for a rational solution of the problem was the electric current itself. How well this has been accomplished is shown by the successful introduction of the circuit breaker, now so universally used in all large power plants. That the magnetic property of the electric current was the means best adapted for the actuation of the protective device, and gravitation the most reliable force for governing its operation, is seen by the great superiority of the circuit breaker which depends entirely upon these forces, over those in which the effect of the actuating current is subject to variation due to extraneous conditions.

PROTECTION AND WHAT IT SHOULD BE, AS APPLIED TO A LARGE MANUFACTURING PLANT.

In treating of this subject the tendency of the engineer has been to regard it almost entirely from an electrical point of view, incidentally, if at all, considering that which affected the real success of the manufacturing establishment employing motors; namely, constant service and lowest cost of production. Before entering further into this matter, let us see what is absolutely required to give a manufacturing establishment protection worthy of that name, when using electrical power transmission.

First: To secure protection of the electrical apparatus from motor to generator.

Second: To provide a method which will afford ample protection for the machinery to which electric motors are attached.

Third: To secure a freedom from interruption of production, and avoid the exasperating delay which is experienced in replacing any part of the protective device after the same has been called into service.

Fourth: After protecting everything in the shape of machinery, the safety of building and electrical apparatus and providing against the stoppage of production; the matter of reducing to the lowest possible point the liability of accident to the operators required to handle either motors or machinery must be considered, as indeed this is a matter of supreme importance.

That all the above mentioned features are ever present, confronting the engineer, who is responsible for the successful operation of a manufacturing plant, is confirmed by the large number of so-called protective devices already offered to the public.

At present a very large part of the labor of the electrical engineer and the manufacturers of this kind of electrical apparatus has been directly in one line, that of protecting the electrical apparatus from the effects of over-heating and the building from fires which might occur from heavily overloaded circuits.

As this feature is commanding a large share of attention in the electrical press and manufacturing world, it would seem best to devote our time in this article to the field suggested in the last three of the foregoing propositions, which, if satisfactorily solved, of necessity cover all the ground now under consideration by engineers, on the subject of proper and positive protection to electrical apparatus as applied to transmission of power.

The pronounced success during the past two or three years of the direct application of electric motors to all kinds of machinery has put this method of power supply so far in advance of other methods, that, notwithstanding the comparatively high first cost, it is now considered the most economical method and should be adopted by every large manufacturing plant where the work is, in any sense, of an intermittent nature.

Let us now look from the electrical side to that of the manufacturing plant, proper, and see if protection is not even more important and imperative here, where very much larger sums of money are invested, and until now have been wholly neglected except by insurance from fire.

To suggest something which may form a topic for discussion, let us take the case of a printing press to which is directly connected an electric motor. The cost of the printing press is, roughly speaking, $3,000.00, and that of the motor equipment $300.00. (These are nominal figures which vary with the class of press used and character of work required from it; the cost of motors also varies considerably, but these figures are conservative and fully within the figures for which good apparatus can be purchased.) Allowing the electrical to be one-tenth the cost of the mechanical installation, does it not seem strange that it has always been the motor which it has been the sole idea of the engineer to protect, notwithstanding that its cost is insignificant as compared with the value of the machine to which it is attached? Is it any wonder that the manufacturers of costly machinery, such as printing presses, have looked with doubtful eye upon the method of direct motor application, whether it be by gearing or having the armature of the motor keyed to the main shaft of the press? The manufacturer well knew that for a short time the motor was capable of producing perhaps five times its rated output, and realized that if this period covered only a few seconds there was a great probability that it would be sufficient to ruin the press should anything occur which would tend to stop it suddenly. He did not feel that there was even the protection which is afforded the presses when driven by belts, for these would slip when called upon to do much more than the normal work of driving the press.

The writer takes the same ground as the machinery builder, and when the representatives of companies manufacturing electrical apparatus were asked about this matter, they invariably assured the purchaser that a fuse inserted in the circuit supplying the motor with current would provide against all possible trouble of this kind. It was tried; the fuse worked in some cases and we began to take courage, thinking that perhaps we were too particular and that the fuse afforded the required protection. It was seen, however, that the blowing of the fuse might serve to protect the motor but not the press.

It is impossible to change over from one method of operating machinery to another without meeting failures, due perhaps to nervousness on the part of the operator when called upon to do a thing for the first time; and certainly it was so when motors were first used in this manner. The sudden turning on of the controller naturally blew the fuse, which too often was sufficiently increased in size to prevent this annoyance. But at its best the fuse served only to protect the motor, the requirements of the motor-driven machine being altogether overlooked. To better appreciate the shortcomings of the fuse in this respect, it is only necessary to understand the conditions under which it operates to open the circuit in which it may be placed.

The effective energy which must be supplied to the fuse is made up of the following quantities: First, heat sufficient to raise the temperature to that of the melting point of the fuse; and, second, an additional amount of heat proportional to the mass and latent heat of fusion of the fuse, while in addition to this, the heat, being radiated by the fuse and its terminals, must be supplied. It will be seen from a consideration of these facts, that the fuse requiring a relatively large excess of energy to effect its operation, will permit a proportional excess of

power to be supplied to the motor. The damage which may result from this may perhaps be more readily seen by an example. Suppose a foreign body gets into the working parts of a machine which is directly connected to a motor. The power supplied by the motor is now expended in the wrecking of the machine, the weakest parts yielding first to the strain. Only a very short time is necessary for the execution of great damage. The possibility of damage is then limited only by the energy required to blow the fuse.

It was only upon the advent of the modern circuit breaker that protection worthy the name was secured for motor-driven machinery. Owing to the much lessened energy required in the operation of this device, the time required upon the occurrence of an abnormal flow, for the opening of the circuit, is minimized, while, in addition to this, the heavier overloads are made to contribute some of their energy to the acceleration of the circuit-opening switch, thereby still further decreasing the time of opening.

It may thus be seen that by the use of a properly constructed circuit breaker, the excess of power which may be communicated to the machine is vastly reduced as compared with the fuse. In fact, the time element is so lessened that the possibility of damage to machine as well as to motor is practically limited to that due to their combined momentum. What this is in each individual case, makes it necessary to decide whether an auxiliary break to take care of the same is necessary or not. This is a question for the mechanical engineer to solve, but, whatever this may be, it does not affect the principles set forth above, and only serves to bring out more clearly how necessary it is to shut off the current instantly and thus prevent the machine from acquiring any additional momentum.

As the question of machinery protection has been given so little consideration, it was deemed advisable to bring to the reader's notice, in rather a minute way, all the possibilities that it may have, in order to give to the subject the importance which we feel it deserves. In the foregoing, a reference was made to the comparative cost of a printing press and that of the necessary electrical equipment to drive the same; i. e., $3,000.00 for the former and $300.00 for the latter—a relative value of ten to one, which justifies the statement that the protection of machinery is a much more important consideration in electrical transmission than that of the motor. Can the electrical engineer afford to neglect this important feature of machinery protection and still hope that his customer will secure satisfactory results? For, after all, it is necessary that the new system as a whole shall be made more productive, and thereby more profitable, than the old.

It may be assumed that our third proposition is intended more especially for the manufacturer than the engineer, but, taking the ground that that which is of importance to the buyer concerns the seller also, we believe it is worthy of the close attention of both. As the writer has had an extended experience upon the application of electricity to printing machinery, he hopes to be able to treat this branch of a manufacturing business in a more positive manner than he could do should he endeavor to extend its scope into a more general or theoretical field.

Referring once again to the printing press, with its electrical equipment cost (which we assume to be respectively $3,000.00 and $300.00), let us see what the production of such a press should be when it is running for three hundred days in the year on a fairly good class of printing, and what costly affairs stoppages of presses are, no matter what the cause. A press should earn an average of $10 day or $3,000 a year. This is not intended to express net earnings but simply the average gross earnings for the press on commercial work, and we assume that it is running on such work continuously. It will be seen that delays caused by an accident to a press may prove much more expensive to the manufacturer than the actual cost of the repairs to the press itself, as a delay of a week means a loss of ten dollars a day or sixty dollars, and serious accidents often mean a month of working days or two hundred and sixty dollars, aside from the cost of repairs, which experience has shown are not to be lightly considered.

Nor is it to be forgotten that the press, to which an accident usually occurs, is generally running on a piece of work which must be completed within a given time. This means that we must lift the form and place it upon another press which has to be "made ready," perhaps interfering with other work, and all this additional cost must be borne by the manufacturer without any return for the same. Is not the manufacturer fully justified, then, in demanding that his machinery and output be equally considered with that of the electrical apparatus in the matter of protection? If the protection of apparatus worth $300.00 is deemed so important as to occupy, as it undoubtedly does, the attention of the foremost electrical engineers, are we not justified in taking the position that protective devices should be so constructed as to fully protect the manufacturer at all points, and not stop with the electrical equipment alone?

By the use of the highest grade circuit breaker now offered to the public, which fulfils in a very satisfactory manner all the requirements thus far considered, such a saving may be made, not only to the motor but to the machine which it drives, that the loss occasioned by stoppages and on account of repairs will be practically eliminated, and the device will pay for itself many times in the first year.

The delays incident to the blowing and replacement of fuses are perhaps more annoying in newspaper and publishing offices (where mails have to be met and where the time for the completion of a particular piece of work is limited), than in most classes of manufacturing, but in any case the saving is so important as to amount to very much more than the cost of adequate apparatus. Indeed, it would seem to be the best paying insurance which the manufacturer could possibly obtain. Such delays as we have been considering are practically unknown when the fuse is replaced by a thoroughly mechanically and electrically constructed circuit breaker.

With the more universal adoption of the individual motor in electrical power transmission, comes also the question of protection to operatives employed in handling the machinery. This is of so much importance that most of the States in this country have appointed inspectors to visit all manufacturing establishments and see that the proper precautions are used, and every means employed to lessen the danger to the employees, of whatever nature it may be. With all the precaution taken to prevent accidents, it is impossible to do away with them entirely. Strange as it may seem, the carelessness or fool-hardiness of the employees themselves are mainly responsible for most of the accidents which occur to-day, thanks to the hearty co-operation of inspectors and employers in their endeavors to make accidents practically impossible. Yet I know of nothing to prevent a man from placing his hands in close proximity to running gears, and if he happens to have a piece of waste in his hands and the same gets caught, the resulting damage is only limited by the quickness with which the machine can be stopped. Several such cases have come under my personal observation and only the prompt opening of the circuit breaker prevented very serious results. In one case a man's fingers were pulled into a train of gears, he endeavoring to clean the press while in motion. His fingers were badly jammed, but the opening of the circuit breaker stopped the press before any serious damage was done, and thus saved the man three fingers. Another case was that of a man who got his arm caught between the two cylinders of a press. He was fixing the packing on one of the cylinders and motioned to the feeder to reverse the press. Instead, he started it ahead suddenly, with the result that his arm was drawn in between the revolving cylinders, and again owing to the instantaneous opening of the circuit breaker the pressman escaped with a severely bruised arm, instead of crushed bones as we had all expected.

These serve as examples upon which to base a requirement that protection to operatives is not a matter of minor importance and should not be put aside with the remark, "Let the employees keep their hands out of the machinery—we cannot protect everything and everybody." To be sure, we have no electrical or mechanical device which will make brains for the ignorant or prevent careless operatives from getting hurt, yet devices can be made, as we have seen, which reduce the results of such carelessness to a minimum, and their employment should become more general as the successful operation of them becomes better known.

Having thus considered in detail the protection demanded by a large manufacturing plant using individual motors as the method of power supply, we are confronted with the proposition—can these demands be met to the satisfaction of all concerned—to the builder of machinery, as well as of electrical apparatus, and to the manufacturer using them? If such is

the case, what is the device necessary to fulfil the requirements, and is it commercially obtainable?

With reference to the fuse, we have only to read any of the scores of valuable papers written upon their action to fully justify us in writing against it "not satisfactory" and passing on. As the current itself may be the means of protection, as well as that of propulsion, the method of opening the circuit electrically should be employed. This has been successfully accomplished in the modern circuit breakers which operate on the inverse time element rather than the constant time limit.

The ultimate requirements of a circuit breaker are that we can rely upon it to do all that we have shown it should do, and operate successfully, not once, twice, or for a month, but always. When this ceases to be the case, the magnetic circuit breaker will be superseded by some other means of protection.

To produce such an instrument, the highest skill, electrical and mechanical, is required. Long study of the existing state of the art and the conditions under which circuit breakers operate is necessary, and the closest attention must be given to every detail of manufacture.

With this an accomplished fact, such results are not the only reward, however, nor should they be. The public will cheerfully pay, not only for the labor and material used in its production, but also a profit sufficient to encourage the maker and enable him to continue the work, for the perfect is never obtainable and is only reached approximately. In electrical science, perhaps more than in any other, we are never able to write the word "Finis."

Public Control, Ownership or Operation of Municipal Franchises?—IV.

With Special References to Electric Lighting.*

By R. R. BOWKER,

(Vice-President and General Manager New York Edison Co.)

OTHER ENGLISH CITIES.

OUTSIDE of London there are recorded eighteen private electric light companies and thirty municipal plants, the trend being evidently toward municipalization. The largest systems are those of Manchester, a municipal plant which last year produced 1,748,000 units at an average price of 5.25 pence and an average cost of 3.01, or fifty-seven per cent. of receipts; Liverpool, a private company, with 1,185,000 output, average price of 7.3 pence and average cost of 3.49 pence, or forty-seven per cent., and Glasgow, a municipal plant, with 1,090,000 output, at an average price of 5.58 pence and cost of 4.12 pence, or seventy-three per cent. Birmingham, noted for its municipalization of industries, decided to permit the new industry of electricity supply to go into the hands of a private company for the parliamentary period of fifty years. Of the private companies one, and of the corporations eight show greater expenditures than receipts, these being mostly small systems, only one having more than £3,000 income. At Blackburn, a municipal plant, the average price is 5.91 pence and the expenditures 10.1 pence, or 171 per cent., so that the taxpayers pay 4.10 pence on every unit sold to consumers. At Dover, a private company, the average price is 4.75 pence and the cost 8.80 pence, or 185 per cent., so that the shareholders pay 3.05 pence toward each unit sold to consumers. The highest price charged by a private company is 7.76 pence; the highest price charged by a municipal system is 6.50 pence; the highest costs are 10.1 pence at Blackburn, and 8.8 pence at Dover, an excess of cost of 1.3 pence on the municipal plant. The lowest cost is 2.72 pence in the Yorkshire private company and 2.66 in the Whitehaven municipal plant, a difference of .06 pence—practically the same. Comparisons even here are not accurate, because, though the Board of Trade returns are on closely parallel lines, they are not entirely the same, and the variants of locality cannot be considered. The closest comparison possible, perhaps, in the world, is between Manchester and Liverpool; the Manchester municipal plant, though installed so late as 1893, is of an old and almost obsolete type; the Manchester output is fifty per cent. greater than Liverpool and the cost is correspondingly lower. The figures show practically a "drawn game" as between private companies and municipal plants in England.

England has had rival telephone systems, that of the National Telephone Company and that of the government. Competition has been keen. The government system has held but 1,000 out of over 100,000 subscribers. Almost all the government exchanges have been abandoned, and the most important one existing, that at Newcastle-on-Tyne, has but one-third the number of subscribers of the private company. The government postal service was so much affected by the telephone system that Parliament passed a bill authorizing the Post Office to take over the trunk or long-distance lines, so that these lines are now maintained and operated under the direction of the postal authorities, and subscribers between the exchanges of the private telephone system are connected through the government postal lines. It may be mentioned that in Stockholm, where there is like competition between a government and a private system, the private system is also getting the lead.

NEW YORK.

New York owns most of its water front; its gross dock rentals, amounting in 1895 to $2,084,382, are paid into the sinking fund, but the expenses of the Dock Department, $1,061,697 in 1895, and the interest on dock bonds for $27,053,000, practically offset these. The city, indeed, seems to get less from its docks than if they were private property paying taxes. New York leases ferry privileges each ten years, at public sale, to the highest bidder, who must take over the operating plant at appraisement value—an excellent plan, bringing the city $346,598 rental in 1896.

New York owns and operates its water supply as well as its sewerage system. The water "rates" and meter returns at ten cents per hundred cubic feet, $3,852,396 in 1895, are paid in gross into the sinking fund, but the expenses on water account, $1,808,264, in 1895, reduce the net revenue to about $2,000,000, which is nearly offset by the interest on outstanding water bonds of $44,126,300. Interest on its full cost not accurately known but estimated at $78,000,000 would show a loss.

New York (Manhattan Island only) has four gas companies, the Consolidated including six former companies, the Equitable including the new East River Company, the Mutual with a provision in its charter against consolidation, and the Standard. It is expected that one new company will practically, if not in form, consolidate most of these interests. There have been a number of gas mains in one street. The gas companies publish no statistics of output. The price, as high as $2.25 per 1,000 cubic feet a few years ago, has been reduced by operating improvements, by competition and by legislation to $1.20 per thousand feet, the law of 1896 reducing it 5 cents per year from $1.25 till it reaches in 1901 $1.00. Oil chiefly is used for fuel. When the Edison Company began incandescent electric lighting in 1882, gas stocks dropped nearly one-half, but despite all electrical developments, the gas product has increased year by year. The four companies have a stock capital exceeding $53,000,000 and bonded debt above $6,000,000, chiefly at five per cent. The stocks show a market value ranging from $128 to $335, or an excess of $30,000,000 above par, reducing the dividend of 4 to 12 per cent. to about 4 per cent. on market value.

New York (Manhattan Island only) has seven electric central station systems with fifteen generating stations and 400 to 500 isolated plants, aggregating probably 660,000 incandescent lamps, 14,500 arc lamps (of which 2,815 are city street lamps), besides 28,500 h. p. in motors, making an equivalent of over 800,000 sixteen candle power incandescent lamps, or with motors, over 1,200,000 equivalent. There are as many as five competing conductors on the same thoroughfare. The Edison Company controls the Manhattan and Harlem high tension systems, and the United (Westinghouse) Company the Brush arc-light system, showing the trend toward consolidation.

*This paper is written from the point of view of the economist and citizen, but with the data and experience gained as the executive of the New York Edison Company. To my mind, this should not involve opposition of interests; as he most serves his party who best serves his country, so he most serves the interest of a public-service company who best serves the public. I mention the relationship, however, to forewarn readers of any unintentional bias. It is difficult for any outside the buisness cited, in an academic discussion, to obtain real bases of comparison.—Reprinted by permission from Municipal Affairs, the Reform Club Quarterly.

Only the Edison Company prints a report. It has a stock capital of $8,000,000, paying originally four per cent. and now six per cent., the market price of $125 making this five per cent. on actual investment cost, and $6,500,000 in bonds, paying five per cent. interest. It had (November 30) 7,422 customers, 345,280 incandescent lamps, 4,317 arc lamps and 18,874 h. p. in motors, the equivalent of 673,484 sixteen candle power lamps, making it the largest electricity supply company in the world. Its returns in 1895 were $1,771,229, or including the high tension system, $2,222,737. The base-rate for incandescent electric lighting is one cent per sixteen candle power lamp hour (twenty cents per unit), ten cents per arc lamp hour and 10 cents per horse power hour, but all these rates are reduced by discounts and a wholesale base-rate of ten cents per kilowatt hour is made for general use. The average Edison return in November, 1897, was 8-10 cents per 16 candle power lamp hour for incandescent lighting with or 3-4 cents without lamps, or 11½ cents per unit for all services. New York City pays forty cents per night for standard arc lights, or $146 per year, being practically four cents per arc lamp hour, forty-five cents for like lamps in parks, etc., and fifty cents per pair for the Fifth avenue smaller lights. This price is reckoned to cover little above actual cost, including subway rental, of city lighting to the companies, which get their profit from commercial lighting in the same streets. Small anthracite coal costs in New York about $2.75 to $3 per ton, or "alongside" dock, about $2.25 to $2.50. No electric lighting company other than the Edison has paid dividends, except the Brush Company in its earliest years, when the price of city lighting was much higher, and the total share and loan capital of all companies averages much below par.

After Edison in 1882 had proved that electric lighting by underground conductors was feasible, a law was passed requiring all electric wires to be placed in subway ducts. Two subway companies now exist, one for high and one for low tension conductors, charging a rental prescribed by the Board of Electrical Control, a municipal commission, varying with size of duct; the rental for standard three-inch duct is $1,000 per mile, which when street lighting only is furnished is $50 per year per lamp at the usual distance of 250 feet apart. The Board of Electrical Control reported in 1896, 707 miles of ducts for high tension conductors, 211 for Edison low tension conductors, 950 for telephone and telegraph conductors and 56 of ventilating pipe. The city has had the right since January 1, 1897, to take over these ducts, subject to liens and leases, at cost and 10 per cent. per year profit (less dividends actually paid), and free ducts must be furnished for the police, fire and other city departments. House connections must be made at the expense of the supply companies, but all ducts built by or for these companies are in the legal ownership of the subway company. Besides this subway system, New York has in its subsoil a steam-heating system and a pneumatic system for the telegraph companies, producing a complexity probably beyond parallel elsewhere. It has also an oil pipe line across the city. New York receives nothing directly for its subsoil privileges except a ridiculous sum, $141 in 1895, from one gas company, and a franchise fee, $2,587 in 1895, for the oil pipe line; but the supply companies, besides paying taxes to city and State, pay also the expenses of the State commissions and boards of control.

The New York street railway system has been in process of consolidation for some years until now there remain chiefly two great operating companies, the Metropolitan and the Third Avenue Company. These are both private corporations, each transferring on its own system within the single fare of five cents. The four lines of elevated railway, originally built by two competing companies, are now consolidated into the Manhattan Company. The city has no specific rights of control over these roads, but receives certain license payments per car and other franchise payments from railroads, amounting in 1895 to $352,288.

The new charter for Greater New York makes the rights of the city in its water front, streets, etc., inalienable, and prohibits new franchises for a longer period than 25 years, with renewals optional on the part of the city aggregating 25 years more. On the termination of a grant, the plant shall become the city's property either without payment or at valuation, as the grant may prescribe; if the city takes over property without compensation, it may operate the plant or make a new lease, but if compensation be required, the city shall itself operate for at least five years—an unusual and extraordinary provision. Every grant shall provide for efficient service at reasonable rates. The jurisdiction over gas, electricity and like industries passes to the Commissioner of Public Buildings, Lighting and Supplies; and he is required to provide for tests of gas, of meters and of electric wiring. Private consumers may require a test of meters by the official inspector, the consumer paying for the test if the meter is accurate and the company if it is not.

The Proposed Holyoke Municipal Plant.

The city of Holyoke, Mass., voted on December 14 to go into municipal lighting, and the Holyoke Water Power Company has voted to sell to the city both its electric and its gas plants. It has filed a schedule of plants and price under date of January 8 with the city clerk, according to the Massachusetts law, asking $1,000,000 for the entire outfit.

The Jersey City Water Supply.

The water supply of Jersey City, under political management, instead of showing an annual profit, as it would under private management, shows an annual deficit. The water is supplied at a central point by a private company. The distribution is through public mains, yet the administration of the Water Department costs more than the water. Similar results would be shown by each of the common services required by a city under existing conditions. If the city owned the gas, electric light and power and telephone plants, each of these would produce another deficit, and the service would decline in quantity and quality.—Jersey City, N. J., Journal.

MUNICIPAL OWNERSHIP is to be debated at the Educational Alliance Hall, New York City, on February 16, by Mr. E. M. Grout, in favor, and Mr. A. R. Foote, against.

MISCELLANEOUS

A Proposed New Method of Charging a Sphere Electrostatically.

BY GEORGE H. MORSE.

THE introduction of a proof plane into an electrified sphere for the purpose of showing that no electricity can be withdrawn from the latter in this manner, is a common experiment. Even if the plane be itself electrified before being introduced, it will come out entirely neutral, all of the electricity having passed to the outside surface of the sphere. In these experiments the proof plane is, of course, understood to have touched the inner surface of the sphere for at least an instant.

Now is it not easy to conceive that an unlimited quantity of electricity at any potential may be thus carried within and imparted to the sphere by repeated introductions of the electrified proof plane? Of course, the mechanical force required to push the charged proof plane into the sphere would increase, as also the potential of the latter, with the quantity of electricity imparted to it.

In place of so laborious a method as the above we might employ a rubber or silk belt running over two pulleys, one within and one without the insulated sphere. A quantity of electricity could then be imparted to the side of the belt approaching the sphere from some constant source by means of metallic brushes. This electricity would then be carried into the sphere upon the belt where it would be collected and distributed to the former through the pulley wheel and its shaft, which should work in metallic bearings within the walls of the sphere.

Another, and perhaps a more practical, arrangement would be, to allow the outside edge of a revolving glass or rubber disc to enter the sphere and act as a carrier, the electricity being collected by brushes in contact with the inner surface. In

this arrangement, rubbers acting directly upon the disc could produce the electricity as in a frictional machine.

The writer confidently believes that unusually high potentials may be attained by apparatus arranged according to the above principle.

The Eiffel Tower Struck by Lightning.

AT a recent meeting of the International Society of Electricians at Paris a photograph was shown of a flash of lightning as it struck the top of the Eiffel Tower. This photograph was taken by M. G. Loppé. The increased thickness of the flash is probably due to the fact that at the time of its occurrence

A REMARKABLE LIGHTNING STROKE, EIFFEL TOWER, PARIS.

rain was falling in torrents. At the right of the scene are shown the arc lamps in the yards of the Western Railway, along the Seine, the image of which is also enlarged, due to the same cause.

Electricity for Balky Horses.

Electricity has more than once been suggested as an agent for conquering a balky and lazy horse. In one case recently a very high-spirited and valuable animal, but extremely vicious and balky, was cured in one hour with the aid of a three-volt dry battery. The officials of the Western Pennsylvania Humane Society were notified some time ago that Thomas Rodgers, of Avalon, was using the dry battery on his horse, which was as bad as a valuable, high-bred horse could be. Superintendent T. M. Porter investigated the case, and he gave Rodgers a hearing before Justice William Griscom, of Avalon. Rodgers said his horse was worth $1,000 if he could be cured of balking and one or two other vicious habits. He had offered $500 to anyone who could manage the animal, and at last consulted Dr. T. C. McNeil, city veterinary. The doctor advised Rodgers to try electricity, and he bought a three-volt storage battery, and by means of three wires connected each side of the bit and crupper with the battery. The horse was hitched to a road cart and at first refused to move, standing with all four feet in a braced position. Rodgers then had the wires connected to the battery, which was placed in the cart, and at the first push of the button the horse jumped, snorted and then moved off. Each day for a week he went through the same lesson. This was the testimony brought out at the hearing, and as the veterinary and squire thought three volts was not sufficient shock to hurt the animal, Rodgers was discharged.

TELEPHONY AND TELEGRAPHY

Telephonic Train Dispatching.

The new Michigan State Telephone Company has contracted with the Detroit and River St. Clair Electric Railway Company for the construction of a train dispatching telephone system extending from Mt. Clemens to Marine City along the route of the road, touching Chesterfield, New Baltimore, Fair Haven and Algonac. Branch lines will be built to Pearl Beach, Miller's and Starrville. The system will be used also as a toll line, having connection with the central office at Mt. Clemens. Work will be commenced at once, and the entire system will be in operation February 15.

Cheap Telephone Rates in Berlin.

Reason why Germany wants to gobble up China is shown in the following dispatch of January 1: "The annual charge of $37.50 for telephone service will in future be replaced by a yearly rent of $12.50 for the apparatus plus the small charge of 1 pfennig (about one-fourth of a cent) for each conversation by private persons, 2 pfennigs for business men and firms, and 3 for clubs and cafés, etc. Business men are strenuously opposed to the proposal that they be charged more than any others."

Control of Telegraph Cables.

At the request of the Secretary of State, Acting Attorney-General Richards has given an opinion on the question of the authority of the President, in the absence of legislation in the matter, to control the landing of foreign telegraphic cables. The question was raised by the action of the French Cable Company, in landing a cable at Cape Cod without the express permission of Congress or the President. Mr. Richards' conclusions are as follows:

"The President has the power, in the absence of legislative enactment, to control the landing of foreign submarine cables. He may either prevent the landing, if the rights intrusted to his care so demand, or permit it on conditions which will protect the interests of this government and its citizens; and if a landing has been effected without the consent or against the protest of this government, respect for its rights and compliance with its terms may be enforced by applying the prohibition to the operation of the line, unless the necessary conditions are accepted and observed."

"Independent" Telephone Companies and the Berliner Microphone Patent.

WE give below full text of a letter issued under date of January 1, 1898, by the Independent Telephone Association of America, signed by Mr. H. D. Critchfield, and dated from Mt. Vernon, O.:

You are urged to carefully read the following letter, which is upon a subject of personal interest to you and all others similarly situated.

You are undoubtedly aware that the American Bell Telephone Company has brought two suits on the Berliner patent and has been and is threatening to bring many others against owners and operators of independent exchanges. The Bell people, of course, claim that the Berliner patent covers all forms of microphone transmitters used in connection with a battery circuit. The two suits above referred to are pending in the United States District Court for the Northern District of Massachusetts at Boston. One of these is against the National Telephone Company and the other is against the Century Telephone Company. These suits were brought in August, 1895, and have been pending since, but were not vigorously pushed until recently, when the suit involving the issuing of the Berliner patent was decided by the Supreme Court of the United States in favor of the American Bell Company. Since

the handing down of the decision in this case the Bell people are pressing the Boston suits before referred to.

The American Bell Telephone Company, as all must admit, is a thoroughly organized and powerful corporation, and it is only fair to assume that they have been preparing for this day (the time when their right to a monopoly of the telephone business would be questioned) ever since their organization in the '70's, and that their aim has been to get in such shape as that when opposition sprang up they would be in the best condition to combat and crush it out of existence if possible. If they should be successful in the litigation now pending, to say nothing of the numerous other suits they are threatening to bring, it seems, from the best information we can obtain, to be their purpose to make application simultaneously in all the other Federal District Courts to restrain the manufacture or use of the microphone transmitter and to procure temporary injunctions against operators of independent exchanges, which, of course, they will seek to have made perpetual upon final hearing. It is needless to suggest that the granting of even temporary injunctions and the closing up of independent exchanges would be fatal to the independent telephone interests, even though it were possible in a few months to procure the dissolution of such injunctions.

The Independent Telephone Association of the United States was organized for the mutual benefit and bringing together of all independent telephone interests in the United States. There are many things which this Association contemplates, but the immediate and pressing call for action is with reference to the patent situation. The organization, through its officers and advisory board, has been and is now, taking most comprehensive and vigorous action and making thorough preparation to prevent further litigation so far as possible and to take care of it when it comes. To this end there has been retained as able counsel, skilled in telephone and patent law, as the country affords, and practical and theoretical telephone experts, with a thorough knowledge of telephony, who are now engaged in making experiments and gathering data, both in this and foreign countries, with the intention, and for the purpose, of being ready at a moment's notice to take up the defense of suits which may be brought against any member of the Association on the Berliner patent, at any point in the United States, and to throughly and vigorously defend the same without cost to the member, except its proportionate assessment as contemplated in the constitution, not only to do this, but to prevent, if possible, the bringing of such suits and the granting of preliminary injunctions.

The work which the Association has undertaken, and is now prosecuting, has and will require a large amount of money. It is a question of meeting a powerful enemy with its own weapons, and this can only be done by joining our forces, raising the necessary funds to prepare for and fight such cases; it is simply a matter of uniting to do that which individual companies are wholly unable to do. You can readily see that no single exchange, or no small number of them, will be able to meet such a large expense. It is confidently believed that if the objects of this Association can be carried out that the Berliner patent will fail, but if such steps are not taken, and all possible defenses set up in any suits which may hereafter be brought against members of the Association, and sustained by proof, the danger from the Berliner patent is great and imminent. Of this there can be no doubt.

Satisfactory progress has thus far been made in the organization of the Association, and it is an accomplished fact, but its power for good and its ability to protect its members depends upon its strength, numerically and financially, and all independent organizations are vitally interested in its success. When the patent situation is cared for, vast sums of capital will seek investment in this field, both in exchange work and long-distance lines, and the accomplishment of the latter is greatly to be desired. You undoubtedly see daily the benefits that would come to you from having first-class long-distance connection with all the other independent exchanges in the country, and especially to have exchanges in large cities and connection therewith. But the first thing to do is to protect ourselves against the common enemy and its patent claims. This can only be done by organization, and any delay in this work is extremely hazardous.

Again let it be said that the whole thing seems to depend upon the care taken and thoroughness in preparation for defense. It is confidently believed that the Berliner patent has long since expired, but that a systematic and thorough effort has been made by the Bell Company to prolong its existence, and if all is not done that can be done to defeat their claims, they will continue to enjoy the monopoly of the telephone business in the future, as they have in the past; the money invested in the independent movement will be lost, and competition wiped out of existence.

A similar letter has this day been sent to each of the directors of your company, and to the manager of your exchange, with the hope that you will take this matter up at once and become a member of this association, and contribute your share to the common defense. A copy of the constitution is herewith inclosed. You will see that the management of the affairs of the association is vested in the officers, advisory board and executive committee; that the members of the excutive committee are selected from each State; that this committee in turn selects the advisory board; that the advisory board is responsible to the executive committee, thus bringing the management in close touch with the individual members of the organization. The constitution also provides that the advisory board may levy an assessment not to exceed 50 cents per telephone, and 50 cents per mile for pole lines carrying toll wires, in any one year. This is the maximum amount for which you could be called upon under any circumstances; but since the adoption of this constitution unexpected assistance has enabled the advisory board to limit the assessment to 20 cents per telephone, and 20 cents per mile of pole line, and no further assessment will be made during the current year. It is believed that this will accumulate a sufficient fund to take care of all expenditures required for that period, and, as the bulk of the expense comes the first year, it is believed that a small assessment, not exceeding 3 to 5 cents per telephone and mile of pole line, together with the membership fee and assessment to be paid by the companies hereafter joining the association, will be sufficient to maintain the organization in the future. This, you understand, means that any company becoming a member of the association, whether now or hereafter organized, must pay its full proportion upon entering, namely: ten dollars ($10) membership fee, and 20 cents per telephone, and 20 cents per mile of toll line, it being the purpose and positive intention to treat everybody exactly alike, and not to allow such as may come in at the eleventh hour to reap any benefit for which they do not pay their full share. The State organization will not be disbanded, but as the national organization takes its place, covers a much broader field, and constitutes a much more powerful organization, no assessment will be made on account of the State organization hereafter.

An application for membership has been inclosed to the manager of your exchange. The membership fee and assessment must accompany this application, and check or draft for the amount made payable to W. J. Vesey, secretary, Fort Wayne, Ind., and forwarded to me at Mount Vernon, Ohio, upon receipt of which the secretary will forward you an official receipt for same.

Important steps are contemplated by the association, and must be taken in the near future. For this reason you are urged to give this matter your prompt attention, that the organization may know that it will have the funds necessary to carry out its plans, and that it is safe to incur the necessary expense therefor. The work of organization is being carried on in other States prominently identified with the independent movement.

Telephonic Wire Tapping in Ohio.

The Central Union Telephone Company, at Columbus, O., has promptly taken up the bribery charge in connection with Hanna's election in order to protect its patrons. This action may make it difficult to secure evidence as to the alleged telephone wire-tapping by which it is said the bribery scheme was discovered. A new law in Ohio makes it a penitentiary offense to tap a telephone wire, and the telephone company will prosecute any one who admits that he was a party to such tapping.

THE WESTERN UNION TELEGRAPH CO. is reported in the daily papers to have some kind of claim against Spain for losses inflicted on its Key West cable business by the censorship at Havana. Vice-President T. F. Clarke is alleged to have made representations to our own Government on the subject.

THE
ELECTRICAL ENGINEER
[INCORPORATED.]

[*Entered as second-class matter at the New York Post Office, April 9, 1888.*]

VOL. XXV. NEW YORK, JANUARY 27, 1898. No. 508.

Central Station Work Here and in England.

THE last number to hand of London "Lightning," January 13, has a very interesting account of a dinner given by a representative gathering of English electrical people to President S. Insull, of the National and Edison Associations. That gentleman, by the way, has just returned home to Chicago, but he found in the British metropolis a very keen desire for information as to our central station work in America, and was in no wise slow to impart it, which few could do as well as he. This dinner was a felicitous illustration of the entente cordiale existing between English and American electrical folk, for while Mr. Insull, as an Englishman born, represented one of the most progressive local American companies, there were at the table such men as Mr. Robert Blackwell and Mr. Parshall, who may be said to represent our manufacturing and engineering sides. Mr. Parshall, a graduate from the great Schenectady shops which Mr. Insull himself created for Mr. Edison, stands high in English estimation, just as we here appreciate in Mr. Insull the virile qualities that have carried him to so high a position in the electric light and power industry of America.

One can read between the lines of the report in our English contemporary. There was evidently much said in confidence around the social board that was not put into type, but the broad lines of the discussion stand out, for as usual, they got to "talking shop," and mighty good talk it must have been, with Messrs. Crompton, Ferranti, Garcke and Wright in the symposium. In a city of scattered numerous stations and no power loads, Mr. Insull preached the pure and simple gospel of big unified generating plants and all the power you can clap on to the circuits. He did not hesitate to give Mr. Ferranti the credit for part of this absolutely unimpeachable programme of advance. He assured them that it would be difficult to find anywhere a city in which electricity for purely lighting purposes was in such universal use as at Brighton. Possibly that was the result of a certain method of charging developed by Mr. Wright. There seemed to be right and reason in it, and he was inclined to try something of the sort as soon as he got back to Chicago. Some of their load in America might be due to the fact that the Edison Illuminating Companies had realized from the first that the all-day use of electric power would ultimately form an important factor in lowering the average cost of current generated by electric supply companies. That was the reason why the Edison companies in America had adopted the policy, as far back as the early eighties, of selling current for power purposes at about half the price charged for lighting purposes. In England, and in London he thought particularly, there seemed a magnificent field for motors, which, when it was taken up, might make some of their American figures look small. The way was to get large consumption by a favorable tariff, and to keep down the charges for interest and works costs by having modern plant and concentrating it in few stations. It could not be expected that a satisfactory load factor could be obtained unless the basis on which the current was sold was one which would encourage long-time consumption. High peaks and high cost of current were the direct result of a prohibitive selling price.

Mr. Insull practices what he preaches, in Chicago, and the latest example, that of Brooklyn, just shown in these pages, with 70 square miles of supply area, all in the network of one big plant generating at high pressure transmission for low pressure distribution, demonstrates how quickly our central station leaders are marking out the new path of progress and entering the new era of universal use of electric current.

Ho! For the Klondike.

ANOTHER great gold rush is impending this spring, and before long thousands of eager gold seekers will be pouring into the Klondike by every avenue of access. There is every reason to believe that the output of the precious metal will be extraordinarily large, so that the perils of the long trip and the inhospitality of the Arctic region will be compensated for by the richness of the reward. It is curious to note how the endless quest for gold shifts now from Central Africa to the icebound recesses of the Yukon, for both of which regions man had apparently little use. But you can never tell where treasure is going to crop up. Once in a while, a far-sighted prophecy is made. Before the discovery of the famous Comstock Lode in Nevada, the late Horace Greeley said: "I believe the Almighty has created nothing in vain, and as I have passed over this awful region, the thought has fixed itself in my mind, that, since it is certainly useless for every other purpose, it may be a land of vast mineral wealth. If that be so, it will take a hundred thousand Californian miners a hundred thousand years even to prospect it." In view of the fact that there are a hundred thousand square miles of auriferous territory in Alaska awaiting the miner's toil, we will surmise with Greeley that Providence had a reasonable object when it thus put the mother lodes in that land of wellnigh eternal ice and snow.

Electrical engineers are deeply interested in the invasion of the new gold territory. This week we illustrate the shipment of electrical apparatus by means of which travel over the dread Chilkoot Pass is to be made safer and cheaper. Meantime, telegraph and telephone lines are penetrating the region, and various plans for electric light and power enterprises are afoot; while one scheme even contemplates the use of steady electric heat for thawing out the icy mass of mud, rock and sand in which the gold lies buried. Why not, and many other uses of electricity which shall tend to reconcile the miner to his exile and make a hard life more pleasant in the desolate Klondike?

How Some City Statistics Are Manufactured.

DISQUIETING reports reach us from the far State of Washington as to some of the evidence brought forward at Tacoma in the trial of City Electrician Joslyn, before the local civil service commission, for incompetency. There is a good deal of mystery around the whole business, and we will not undertake to clear it, for we are quite ready to believe that things are all right and that there are no politics in municipal affairs in that bustling city, way off Northwest. We trust that Mr. Joslyn may be able to clear himself of the charge that he falsified his figures in order to make out that the city would produce current cheaper than the Tacoma Railways Company. Councilman Holgate testifies that Mr. Joslyn intimated to him that the reports were made out at the instance of the municipal administration so as to discriminate against the private company. "Joslyn had told him that the figures were not correct; that many items of expense had not been

charged which should have appeared on the sheets and that if all had been charged the cost per kilowatt would have been increased to more than two cents per hour, while the report showed that each kilowatt hour had cost during the last month only 1.77 cents." As we said above, everything may be all right, but it is little incidents like this that check one's ready confidence in the accuracy of the statements as to the economy of municipal plants.

A New Trouble for the Consulting Engineer.

THE recent agitation in the United States on the part of manufacturers to relieve themselves from the burdens frequently put upon them by the consulting engineer finds a pathetic counterpart in a case recently brought to light in England; but with this difference, that in the latter case it was the consulting engineer who deemed himself the aggrieved party. It seems that a district council called upon a well-known firm of consulting engineers to advise them in a certain matter, and then submitted the identical question to another consulting engineer without informing either of them that the other had also been consulted. Of course, as soon as the fact leaked out, the firm first mentioned above resigned its engagement. The question involved in this instance is one between client and technical adviser, and in this particular case it was evident that the latter had some rights which the client was bound to respect, just as the manufacturer has some rights which the consulting engineer ought not to lose sight of. It is one thing to employ a consulting engineer to draw up a general plan and to call upon bidders to submit their own details with estimates, from which the consulting engineer can select the plan best adapted and for the least cost; but it is quite another matter to impugn either the ability or the honesty of a consulting engineer by submitting the same work to another without due notification to that effect. Such cases are not likely to arise very often in practice, but their casual occurrence serves to show the necessity for some code which ought to be so well known that such embarrassing situations would not occur. Now that the American Institute of Electrical Engineers is about to take up the standardizing of electrical apparatus, why not go a step further and lay down a code which will become an official guide as to the relation between purchaser, engineer and manufacturer? An efficient code of this nature would be helpful to all parties concerned. If, in addition, it embodied regulations as to fees, etc., it would be doubly acceptable to the engineer. A code of this nature adopted by the American Institute of Architects has been found to work very well. In the latter body, infractions of the code, if proved, may be followed by expulsion from the organization. It must be evident that the American Institute of Electrical Engineers has a good deal of work still ahead of it, and we expect it will take care of all of it in due season.

An Imperial Electrical Inventor.

THE career of American electric street railway apparatus in Germany may be destined to be a short and merry one, for the news has come very circumstantially of late that the Emperor himself proposes to invent a new electrical car for Berlin, and, if for Berlin, then for all Germany. A few years back, Prince Henry, the Emperor's brother, repeated all the sensational Tesla experiments with currents of high voltage and high frequency, and not many months ago we noted the fact in these columns that the Emperor, the Prince and some high army officers were taking a special electrical course. This all goes to confirm the rumor. We are sure his majesty can help the electric railway art materially, for it has been said that he has a rolling eye of genius just like Edison's; although we have never seen Mr. Edison roll his eye, unless a wink is included in the expression. But what worries us is that we don't see where the Emperor is to get the time; he is so busy. There is Turkey to be patronized; Greece to be snubbed; Russia to be flattered; France to be flouted; England to be insulted, and China to be cut up, all of which he is giving personal attention to, conscientiously. But his majesty is also otherwise engaged, in oratory, music, art, the drama, yachting and a few other diversions. Now the success of such railway inventors as Sprague and Short has come from pretty close attention to one thing. It is true that Tesla dines at Delmonico's; that Edward Weston delights in his big naphtha launch, his camera or his telescope; that Elihu Thomson and Steinmetz persist in scorching on their beloved bicycles; but, after all, their one serious thought and aim in life is electrical investigation and invention. We are sorry that so far as the Emperor's character has interpreted itself to us, his great genius lacks concentration. This is electricity's loss, but we may all just as well make up our minds to stand it. If there is one constant element in the case, it is the Emperor's inconstancy; and he will soon be forgetting that electric car for a balloon, a gun, a picture or a navy.

Double Decked Cities.

ONE of the plans most in favor lately in regard to the renovation of the New York Elevated and its operation by electricity, has been that of double decking the road. The New York "Herald" has also come out with an illustrated plan for double decking the whole line of the proposed viaduct across the valley at West 125th street, continuing the Riverside Drive northward. There is nothing amiss with such schemes, and such an arrangement of city traffic is certainly more likely and feasible than boring underground in the dark bowels of the earth, seventy or eighty feet from the surface. But we wish to recall the fact that just such a plan, only fuller, with much circumstantial detail, was laid before the old Electric Club of this city in 1891, by Mr. Allen R. Foote, a copy of whose admirable paper on the subject is now lying on our desk. Since that time, many conditions have arisen to confirm his views, and none of them have been more striking than the differentiation of the various means of traffic and locomotion in our streets. Such traffic now is badly in need of sorting out on many main lines of thoroughfare, and the introduction of asphalted streets, electric carriages and bicycles will go on with faster pace than ever when Mr. Foote's ideas are realized of a double-decked city street.

Things That Were Not What They Seemed.

LAST week, in spite of our rule against involving this journal in disputes with other papers, on subjects of a non-technical nature, we felt it our duty to issue a warning to our readers in regard to documents that were being circulated by another electrical publisher against his fellows in the journalistic field. One of these documents was a fac-simile letter, the other was an unsigned circular based on it. The fac-simile letter was signed by the advertising agent of an electrical company, whose president, on investigation, has repudiated it. The unsigned circular purports to prove how the various electrical journals compare as advertising mediums, as shown by the "keying" method adopted by the electrical company, said keying being suggested by the aforesaid publisher, who besides being the only publisher who knew about the matter secured a keying address in the building long occupied by the company, while The Electrical Engineer, for example, was given one across the street—a liquor store. We think our readers can see where the "keying" test might come out, under all these suspicious circumstances—just where it did, although even of this no evidence of accuracy can be obtained; and we think they will also understand its swift exposure when the facts came to the light. To speak severely of such an insidious method of warfare on fellow publishers would certainly be justifiable, but we shall, as hitherto, leave our readers to arrive at their own conclusions. They probably will not have difficulty in guessing the name of the publisher who did this thing, and who, having arranged it all, asked for the advertising agent's letter in regard to it and then announced that the letter was "unsolicited."

ELECTRIC TRANSPORTATION

Rural Electric Roads in Michigan.

IT is probable that in a very few years Michigan will be as liberally gridironed with electric railroads as she is with steam lines now. Already 165 miles of rural lines have been built or are under construction, upward of 400 miles more are projected and nearly as many miles are under discussion. The electric lines already in operation or under construction are as follows:

The Rapid Railroad, from Detroit to Mount Clemens, fifteen miles.

Mount Clemens & Lakeside Traction Company, from Mount Clemens to Lakeside, two and three-quarter miles.

Detroit & River St. Clair Railroad, from Mount Clemens to Marine City, thirty-seven miles.

Detroit, Lake Shore & Mount Clemens Railroad, from Detroit to Lakeside, twenty-six miles.

Detroit & Pontiac Railway, from Detroit to Pontiac, twenty-one miles.

Pontiac & Sylvan Lake Railroad, from Pontiac to Sylvan Lake, three miles.

Detroit Suburban, from Detroit to Grosse Pointe, four and one-half miles.

Highland Park Road, Detroit to Highland Park, five miles.

Detroit, Ypsilanti & Ann Arbor, from Detroit to Ypsilanti, and thence to Ann Arbor, thirty miles.

Wyandotte & Detroit River Line, from Detroit to Ecorse, Wyandotte and Trenton, ten and one-half miles.

Ann Arbor & Ypsilanti, from Ann Arbor to Ypsilanti, over an old steam road built eight years ago, ten miles.

Owosso & Corunna Railroad, from Owosso to Corunna, three and one-half miles.

Interurban Railway, from Saginaw to Bay City, thirteen miles.

Wenona Beach Branch of the Bay City Road, three miles.

Lansing Street Railroad Company to the Agricultural College, three miles.

Grand Rapids Street Railroad, from Grand Rapids to Reed's Lake, four miles, and to the Soldiers' Home, three miles.

Manistee, Filer City & East Lake, from Manistee to suburban towns, eight miles.

Muskegon Street Railroad, from Muskegon to Lake Harbor, six miles.

Holland line, from Holland to Macatawa Park, five miles, and thence south to Saugatuck, eight miles.

All these roads have been built and are now in operation, or will be pushed to completion in the coming summer. The roads projected are more extensive and have a greater mileage than have those already in existence and several of them undoubtedly will materialize either this year or next. The projected lines are:

Detroit to Toledo, fifty miles, with two companies figuring on it and one of them claiming to have acquired most of the necessary right of way.

Bay City through Wisner, Akron and Columbiaville, to Sebewaing, thirty miles.

Lansing, through St. John's, Maple Rapids, Pompeii, to St. Louis, fifty-three miles, with ultimate extension to Midland. The company has already been incorporated.

Lansing, through Danville, Birkett's and Unadilla, to Dexter and Ann Arbor, seventy miles. This company has been incorporated.

Detroit to Romeo, thirty-three miles.

Hart, through Hesperia to White Cloud, thirty-five miles.

Detroit to Pontiac, by way of Redford and the lake resorts, thirty miles.

Pontiac to Flint, forty-two miles; right of way already secured.

Bay City, through Saginaw, Caro, Sanilac Center and Croswell to Lexington, ninety miles, with a probable extension down the lake shore to Port Huron.

Kalamazoo to Battle Creek, twenty-five miles; right of way secured and work will be begun this season.

Dundee to Monroe, seventeen miles.

Lambertsville to Toledo, eighteen miles.

Coldwater to Union City, thirteen miles; also from Coldwater to Fremont, O.

Benton Harbor east ten miles, then one branch to Allegan, sixty miles, and another to Cassopolis, forty miles. The road is partly graded, but the company has become involved in litigation.

The talked-of lines are numerous and new ones are being brought to the front almost every day. The most important of the lines that are still very much in the air are from Grand Rapids to Grand Haven, from Grand Rapids to Muskegon, from St. Louis to Midland, from Marine City to St. Clair and Port Huron, from Battle Creek to Lansing, from Lansing to Allegan and Saugatuck; from Coldwater to Bronson, Quincy and Orland, Ohio; from Sheboygan to Mullet Lake, from Standish to Au Gres, from Saginaw to Flint, from Flint to Fenton. The upper peninsula has several lines projected connecting the different towns in the mineral regions, but the plans have not been fully developed.

Long-Distance Trolley in Kansas.

The Kansas City, Lawrence and Topeka Electric Railroad and Power Company, which was granted a charter by the Secretary of State at Topeka recently, with a capital stock of $3,000,000, has been organized under this charter in Kansas City, Kan. E. B. Purcell, of Manhattan, Kan., a former director and promoter of the Santa Fé Railroad, was chosen president; John G. Johns, a wealthy stockman and railroad promoter of Houston, Tex., was elected secretary; Edward G. Anderson, an attorney of Kansas City, Kan., was made assistant secretary; and James Haggart, of Kansas City, Mo., was chosen treasurer. The directors are these four officers, Henry McGrew and W. L. Wood, of Kansas City, Kan., and T. E. Holmes and A. H. Gossett, of Kansas City, Mo. The company plans to construct and equip an electric railroad from Kansas City to Topeka, and operate it for both passenger and freight traffic. It also proposes to furnish electricity to the cities and towns along the line for manufacturing and lighting purposes. The work of securing the right of way for the railroad will begin at once.

Connecticut Trolley Interests.

The partial report of the Connecticut Railroad Commission, lately published, gives opportunity for the annexed comparison of capitalization and debt of Connecticut trolley companies in 1896 and 1897:

	1896.	1897.
Total stock issued	$9,221,740	$9,770,440
Issued for cash	2,671,240	3,106,940
Bonded debt	8,690,100	9,092,800
Floating debt	849,255	1,071,421

The figures show that while there has been a slight gain in the ratio of stock paid in for cash to stock issued, there is still more than three times as much of the latter as of the former, while the bonded and floating debt considerably exceeds the stock issued. The amount of capital stock authorized is $18,248,000.

The promoters of the projected trolley parallel between Norwich and New London claim that they have secured in Boston the funds necessary to build the line. They have submitted their layout to the authorities of the towns of Montville and Waterford, and the necessary appeal to the Superior Court of New London County on the question of public necessity and convenience will follow.

The extension of the third-rail route for ten miles, from New Britain to Bristol, will probably compel changes in the New England track, and the building of two or three new stations. The third rail will parallel an existing trolley line.

An interesting phase of steam and trolley competition is soon to be that between the New England's "composite" car and the trolley from Rockville to Hartford. The composite car, with its steam motor, will make the distance (about seventeen miles) in considerably shorter time than the new trolley, but has the disadvantage of not running through the streets of either of the terminal cities. The long trolley road recently opened has been well patronized.

LETTERS TO THE EDITOR

The Relations Between the Consulting Engineer Manufacturer and Purchaser.

THE recent discussion of the relations between the consulting engineer, manufacturer and purchaser by the New York Electrical Society was very interesting, but let me here suggest a point or two not then mentioned.

1. Let the manufacturer so build his apparatus that he will not be confined to standard machines, but let him so standardize individual parts that most any new combination of such parts can be made into nearly any special machine desired without greatly enhanced cost or embarrassment to any one concerned. In other words, greatly extend the present system of interchangeable parts so as to cover a much greater field. The subject is too large to be more than hinted at now, but there is room for such a development here as will astonish many as times and ideas advance. More intercourse between the parties named above will materially aid this matter, which is sure to increase in importance.

2. A little better training of the manufacturer's selling agents than the writer has noticed in some cases will aid all of the aims of the discussion the other evening and of this letter.

3. A much greater knowledge of shop practice on the part of consulting engineers is necessary. Want of this has led to a great deal of unnecessary work and expense on the part of all parties concerned.

Such seems to be a brief summary of the whole situation. The writer has had experience with manufacturing and consulting work from which he draws the above inferences.

New York City. JAMES H. BATES.

Exhaust Steam Heating.

IN the issue of Jan. 13, "Sic 'Em" criticises "Le Chat" for straining a point in speaking of 12 pounds back pressure on an engine for heating systems, and promptly proceeds to make a worse mistake by saying that "supplying the engine with an increased boiler pressure equal in amount to the back pressure straightens things out." Does "Sic 'Em" know that the initial pressure is constant for about one-quarter of the stroke and therefore the initial pressure must be increased about three or four times as great as the back pressure is, in order to "make the engine do the same amount of work as before?"

If "Sic 'Em's" article was true, then a condenser would have no further effect than increasing the boiler pressure by about 13 pounds, whereas we all know that increasing the boiler pressure 40 pounds would not add to the power of the engine as much as a condenser would.

The only way to heat by exhaust steam is to use a vacuum system and remove the back pressure, thereby retaining the efficiency of the engine and still benefiting by the otherwise wasted heat units. W. B. LEWIS.

Providence, R. I., Jan. 20, 1898.

No Politics in Detroit's Municipal Affairs.

My attention has been called to your editorial article, "Politics in Detroit Lighting." If there is any place in America where there is not nor ever has been any politics, it is in the Detroit electric lighting plant from its inception up to now. The only reason that made it possible for Detroit to have a lighting plant, was the poor service that it had received from the company furnishing light, and the high price charged. I was one of the original commissioners, and from the first meeting of the commissioners until now, nothing appertaining to politics has had anything to do with the plant or its management.

I am greatly in favor of intelligent and honest discussion on the question of public lighting, and although I believed, and still believe in a public lighting plant for Detroit, I am not prepared to say that every city should own its own plant; but I think those opposed to a city furnishing its own light are not adding any to their side of the argument by saying that politics was the cause of putting in Detroit's plant.

J. L. HUDSON, President.

Detroit, January 18, 1898.

SOCIETY & CLUB NOTES

President H. C. Higgins' Address Before the Northwestern Electrical Association.[1]

IN my few remarks I wish to say something about gas and electric street railways as well as electric lighting. We have in this association several members who represent both those interests, and as they are semi-public enterprises they are to my mind kindred industries to a certain extent. It is gratifying to know that we have bridged over the hard times and are now on the eve of better times. People have been economizing in gas and electric light and and in the nickels that in ordinary times have gone to the street railway.

The Edisons, Thomsons, Houstons, Brushes, Van Depoeles, Westinghouses and others have invented and sold us the excellent products of their wonderful genius, and at excellent profits to themselves, but they have neglected one very important thing, that is, directions to us, or how to operate the goods with profit to ourselves, which the hazard and annoyance, and the necessary investment would justify.

Hazardous because of the many dangerous things that can take place in connection with our plant, that would be ruinous to it, such as an opposition municipal plant or a serious accident causing many thousands of dollars, a disastrous fire, etc., and while we do not want to condemn the electric lighting business, I will say that I see before me here the faces of many men who have been in the central station electric light business for years, some of them having grown gray in it, and I do not know of more than one or two instances where they have ever realized one dollar on their many years' investment; still the public think we have too many privileges and are getting rich through the business.

To be sure, we who went into this business in its early history, have had much to contend with, that we do not come in contact with now; we have learned something about the business ourselves, and can now get more efficient help than formerly and at reduced wages; our supplies are much cheaper, and although we have all reduced our prices for light, I am sure that we are all doing better in a financial way, than we were in the early history of the business.

One dangerous element that we have to look out for is the political schemer, who is always working "for the dear people," and the gas and electric light companies are destined subjects of his attack. All our legislative halls from Congress down to our own little municipalities have quite a sufficiency of this element. He is constantly working on some scheme that will defeat the local lighting companies. You may ask me for a recipe for treating him, but I must answer that I have none other than to meet him with good work and honest facts. Give the public good service and fair prices and courteous treatment and the battle is three-fourths won.

The gas business; there is but little use of saying much for it. It will speak for itself, and like the poor, will always be with us. We, who were in the gas business, when the electric light business was first introduced, will remember well how fearful we were, lest the new light should send us out of business; but the genius has not been idle in this branch of the lighting business, for while such good improvements have been going on in the field of electric lighting, improvements in gas appliances and machinery have also been going on, and to-day gas interests and securities stand higher in the financial market of the country than was ever known before electric lighting was introduced, and as yet, neither industry has hurt, but rather helped, the other. Gas is fighting hard to retain supremacy, and I think there will always be a sufficient field for both, if the man from Logansport, hasn't something up his

[1] Abstract.

sleeve to ruin the eyes of the entire human race, in his late invention.

I wish it to be understood that my remarks on street railway matters shall apply principally to street railways of the smaller class, in towns of from ten to fifteen thousand population.

The street railway business has, I think, suffered more within the past two years than any other legitimate business. Not only have the hard times worked against them, but the bicycles have taken a large percentage of their business. The new woman and many of the old ones have hied themselves away from us on their wheels, and both have had plenty of followers. They have quit us cold, but it is to be hoped that they will soon return to us in a changed temperament, for as repair bills for broken bicycles are met with and the many various disappointments which surround wheeling have become unbearable to them such as punctured tires, breakdowns far away from home, etc., have worn out their patience, they will return to us and give up their nickels to the electric car even more willingly than they have ever done before.

It is gratifying, however, to street car men to know that the expenses of operating as well as those of original purchase have been very much reduced. The reduced receipts have had much to do with the reduction in operating expenses so that perhaps after all the reduced receipts have been a blessing in disguise, although the reduced receipts have certainly not been the whole cause of our reducing expenses, for when we first went into the electric street railway business it was all an experiment from start to finish. I might more properly say an experiment from Lynn to Schenectady, clear down the line to the rail bond. We all thought in those days that about all that was necessary was to secure a favorable franchise and the electrical companies would do the rest, but I know of no writing that so fittingly applies to the case as a verse in one of Moore's poems which reads:

I saw from the beach when the morning was shining
  A bark o'er the waters ride gracefully on,
And I saw from that beach when the eve was declining
  The bark was still there, but the waters were gone.

The nickels which we had expected to have supported our enterprise had like the waters gone and left our bark, the street railway, stranded. We certainly have done more for the public than we have for ourselves and our associates in the building up of these electric street railways in the past, though I look forward to the future of this business with considerable hope, and as I have been through the poor track and poor car business, and one of the pioneers in the street railroad park business I feel that it is not egotism to say that I am competent to give some advice to my fellow sufferers in that line. Do not use less than a 60-pound steel T-rail; use good, sound ties not less than 6 inches wide; lay them two feet centers and still closer is better; bond with not less than No. 0 bonds; use nothing less than 0 trolley wire; buy nothing larger than 16 to 20-foot cars for general use, and you cannot make much of a mistake by buying the latest type of generators and car equipments from any of the leading companies making and selling such appliances. With such a track and appliances and cars as I have described you will have a very pleasant business providing your patronage will justify the outlay.

Do not, however, lay any extra line in order to establish a park, unless you can establish it on the edge of a body of water and have a town of not less than 30,000 people to draw from. Do not lay out much money on animals for your park. The park season is short and the balance of the year in which animals must be fed and cared for is so long that except as a matter of pride it does not pay to have a zoological department to your park. People very soon tire of looking at animals. Do not run vaudeville or other shows unless you are so situated that their transportation will cost you but little. I believe that street railway parks should be well enclosed and no one admitted except they pay carfare each way, no matter whether they come by carriage or bicycle. I do not believe that any town of less than 25,000 people will support an electric street railway and give a decent return to its investors, although two towns aggregating a little less than that population and being some distance apart might be good paying properties, although local conditions would have very much to do with this. I have known of towns of this size and seemingly about the proper distance apart, and without a cent of interest to pay and light taxes, almost no insurance and lying in the heart of a good coal district, where they got their coal for almost the hauling, (and although the road appeared to be well managed), still it went into the hands of the receiver for sheer lack of patronage and is still in his hands, and the Lord only knows when it will get out of his hands.

And now in my closing remarks in relation to electric street railroading, while congratulating ourselves upon the pleasant side of the business, I would ask, how long the restless brain or the genius of the nineteenth century or even the twentieth century, coming and already on our threshold, will let us alone? How long will it be before they will have something better to offer us for transporting passengers than an electric street railway? We are already threatened with the airship and the horseless carriage. What will be accomplished in this line is mere guesswork. Let us hope, however, that at least we who are in the business to-day will get a much needed rest from any further experiments.

American Institute of Electrical Engineers.

The 121st meeting of the Institute will be held at 12 West Thirty-first street, New York City, on Wednesday, Jan. 26, at 8 o'clock p. m. At the suggestion of the executive committee the evening will be devoted to a discussion of the "Standardizing of Generators, Motors and Transformers." It is proposed to discuss the question from the technical standpoint, in its relations to the designer, the manufacturer, the consulting engineer and the user. Consideration will also be given to the policy on the part of the Institute in undertaking to bring about the result indicated in the foregoing title.

A meeting of Western members for the discussion of the same subject will be held at the Armour Institute, Chicago, on the same date and hour.

Texas Gas and Electric Light Association.

A JOINT meeting of the executive committee of the Texas Gas and Electric Light Association and Texas Street Railway Ass'n was held at Austin, Tex., Jan. 16, 1898, L. T. Fuller presiding. Those present were: L. T. Fuller, of Calvert; Carl F. Drake, of Austin; C. F. Yaeger, Laredo; Thos. D. Miller, Dallas; R. S. Wakefield, San Antonio, Geo. H. Cushman, San Antonio; F. E. Scovill, Austin; C. L. Wakefield, Dallas; W. E. Holmes, Austin; J. H. Fitzgerald, Houston (by proxy).

After discussion it was decided to hold a joint meeting of both associations at Laredo, Texas, on these days, March 9, 10, 11 and 12, 1898. A letter was read from Mayor Christen, of Laredo, saying that he and citizens of Laredo, would do all possible to successfully entertain members, delegates and visitors. Mr. Yaeger stated that every preparation for the comfort and convenience of members, delegates and visitors would be made by the citizens of Laredo. Hotel accommodations would be ample. The hall for meeting would be provided; a large and convenient hall with light and power service would be available for exhibits and local committees would arrange attractive programmes for entertainment of all in the intervals between business sessions.

Mr. Yaeger further said that the Mexicans who were connected with the lighting, street railway and power plants of the Republic of Mexico, had evidenced great interest in the proposed meeting and that the Mexican Government had, through its Department of Foreign Affairs and through Senor P. Ornelas, Mexican Consul at San Antonio, expressed interest in and tendered offers of assistance as far as possible, for a successful meeting and that a large attendance was expected from Mexico.

It was then moved and carried that an International Meeting of the Texas Gas and Electric Light Association, the Texas Street Railway Association and the Gas, Electric, Street Railway and Power men of Mexico, be held as above and that the joint invitation of both associations be extended to our Mexican neighbors and that a part of the programme be devoted to papers to be prepared by them.

After further discussion a general programme was outlined for separate and joint meetings, including: "The Advantages of Associate Work," by Carl F. Drake, of Austin; "Meter vs. Flat Rates," J. R. Cullinane, Dennison; "Use and Abuse of Electrical Machinery, Apparatus and Appliances" Harry L.

Monroe, Dallas; "A Chapter on Accidents," Geo. B. Hendricks, Fort Worth; "Uniform Voltage and Continuous Service," George R. Cushman, San Antonio; "Street Mains and Services," J. H. Fitzgerald, Houston; "The Ups and Downs of the Manager," J. D. Oliger, Cleburne; "Car Bodies; Their Maintenance and Repairs," Frank E. Scovill, Austin; "Trucks and Their Maintenance," George D. Hartson, Dallas; "Instantaneous Water Heaters," Thos. D. Miller, Dallas; "Experiments in Efficiencies," E. F. Gibbon, Corpus-Christi; "Rail Bonding as a Power Saver," H. C. Chase, Houston; "The Electric Furnace; Calcium Carbide; Acetylene Gas and Other Forms of Gas," J. D. Cox, Galveston; "Rates for Electric Lighting," E. L. Wells, Jr., Marshall; "Miscellaneous Matters," W. L. Hall, Mexia; "Ties; Their Life and Preservation," D. D. Willis, San Antonio.

An interesting programme of miscellaneous entertainments is also being laid out.

Meeting of the Northwestern Electrical Association.

THE sixth annual convention of the Northwestern Electrical Association was held at Milwaukee, Wis., at the Hotel Pfister, Jan. 19-21, 1898. The following members and guests were in attendance:

E. H. Abadie, St. Louis; Jas. Atkinson, M. B. Austin, Mrs. M. B. Austin, E. D. Alexander, Chicago.

F. R. Bacon, Milwaukee; E. K. Batton, Chicago; W. Worth Bean, W. Worth Bean, Jr., St. Joe, Mich.; C. L. Burlingham, F. B. Badt, Mrs. F. B. Badt, F. N. Boyer, Chicago; L. W. Burch, Madison; B. L. Burdick, Milwaukee; C. W. Bacon, Madison; F W. Buss, Chicago; W. P. Bragg, Monroe; C. E. Brown, Chicago; M. Brooks, Minneapolis.

Jac. Cloos, Chicago; H. O. Channon, Freeport; L. M. Cole, A. B. Conover, Geo. Cutter, Mrs. Geo. Cutter, Chicago; F. A. Copeland, La Crosse; A. G. Collins, Milwaukee; A. A. Cross, J. V. S. Church, Chicago; W. L. Church, Milwaukee; J. H. Callouck, Freeport; W. P. Clausen, Frank H. Clark, J. H. Culver, Chicago; W. F. Collins, Warsau.

B. B. Downs, Fred De Land, Chicago; Thos. Duncan, E. R. Draffen, Ft. Wayne; E. L. De Bell, Sheboygan; G. A. Davis, Newark; Alex. Dow, H. L. Doherty, Detroit; A. Donohue, Chicago; Jas. R. Dee, Houghton.

— Eberhardt, W. H. Edgar, Chicago; S. Ellis, Milwaukee; Axel Ekstrom, New York.

A. W. Foster, Chicago; Thos. Ferris, Milwaukee; A. O. Fox, Madison; Hy. Floy, Chicago; F. H. Ford, Madison; E. A. Fox, Chicago.

Ch. P. Gage, Chas. Girjahn, Thos. S. Grier, Ed. R. Grier, Wm. Goltz, Chicago; H. J. Gille, St. Paul; T. F. Grover, Fond du Lac; A. C. Garrison, St. Louis; C. G. Guild, Chicago; C. R. Edman, Milwaukee.

Geo. Hurd, F. S. Hunting, Ft. Wayne; L. A. Hine, J. H. Harding, B. Hartley, E. H. Hammond, J. M. Hill, Chicago; P. F. Harloff, Madison A. D. Hamacek, Sturgeon Bay; H. C. Higgins, Marinette; Geo. W. Stauntton, Chicago.

Prof. D. C. Jackson, Madison.

F. G. Kurz, Appleton; J. M. Knox, Chicago; C. S. Kehler, Milwaukee; C. E. Kammeyer, Chicago; Frank Kellogg, Spencer; A. L. Kuehmstead, Chicago; H. R. King, Milwaukee; C. A. Kehler, Chicago; L. E. Kerns, Madison; P. H. Korst, Racine; O. P. Kissell, Hartford.

J. S. Loomis, H. E. Lang, W. W. Lowe, R. D. Lucas, A. M. Little, Chicago; A. C. Langstadte, Appleton; Otto Langstadt, La Crosse; S. B. Livermore, Winona; A. E. Lucas, Marion; C. E. Lukens, Chicago; J. P. Lord, Waupaca.

N. W. Mixer, J. H. McGill, J. B. McKeague, Chicago; J. S. Maurer, Fostoria; B. M. Myers, Chicago; T. R. Mercein, Milwaukee; C. D. Marsh, New York; W. J. McConnell, J. B. Morrill, J. C. McMynn, — McRoy, Chicago.

F. D. Nims, Muskegon; Pliny Norcross, Janesville.

J. B. O'Hara, Chicago.

R. J. Parvin, Geo. Peck, J. C. Pomeroy, F. L. Perry, Chicago; E. L. Powers, New York; Geo. W. Patterson, Chicago; H. A. Pierce, Negaunee; F. A. Pamperin, Oconto; C. C. Paige, Oshkosh; C. T. Page, Chicago.

F. Raymond, T. D. Retchie, Chicago; J. E. Randall, St. Louis; W. S. Rugg, Chicago; Geo. F. Rohn, Milwaukee; Geo. P. Rex, I. D. H. Ralph, C. A. Ross, Jul. Roe, Chicago.

W. H. Schott, Chicago; A. C. Shaw, New York; B. J. Shockley, Geo. S. Searing, R. F. Schuchardt, Chicago; F. L. Stagg, Madison; R. A. Swain, W. R. C. Smith, C. M. Smith, Chicago; B. H. Strong, Barraboo; Ed. Schuette, Maintown.

W. J. Trott, A. L. Tucker, Chicago; G. M. Thayer, Belle Plaine; A. A. Thompson, Madison.

H. G. Underwood, W. P. Upham, Chicago; E. A. Upham, Mansfield; C. E. Van Bergen, Okonto; Geo. S. White, J. M. Worrell, Jas. C. Wormley, W. Wadhams, Chicago; E. A. Wuerster, Milwaukee; W. H. Whiteside, Chicago; T. F. Whitefield, Milwaukee; Jas. Wolfe, Chicago.

G. E. Yorke, Portage.

The convention was called to order by the president, Mr. H. C. Higgins, of Marinette, Wis., who read an address.[1]

The secretary and treasurer, Mr. Mercein, then presented his report, in the course of which allusion was made to the fact that the National Electric Light Association purposed to make a full discussion of the Municipal Ownership question one of the prominent features of the Chicago meeting next June.

WEDNESDAY AFTERNOON SESSION.

The chair appointed a committee of three to nominate officers and directors for the ensuing year. The election resulted as follows: President, Mr. F. A. Copeland, of La Crosse; first vice-president, Mr. James R. Doe, of Houghton, Mich.; second vice-president, Mr. P. H. Korst, of Racine, Wis.; secretary and treasurer, Mr. Thomas R. Mercein, of Milwaukee. Directors, Mr. E. L. Debell, of Sheboygan, Wis., chairman; Geo. L. Thayer, of Belle Plaine, Iowa; S. B. Livermore, of Winona, Minn.

PRESIDENT F. A. COPELAND, of La Crosse, in assuming the chair, congratulated the association on the gait it had kept up since its organization, and stated that the object of the association was to stand by and aid those engaged in a legitimate business.

MR. PLINY NORCROSS, chairman of the Protective Committee, then presented the report of that committee. This committee had met at Madison several times during the session of the legislature of 1897. Of the 83 electric companies in Wisconsin, probably not five were represented in the legislature at any one time. A bill had been passed taxing every electric light and railway company 1½ per cent. on its gross receipts.

The Milwaukee Street Railway and Electric Light Company paid a tax of $63,000. It was suggested that when the committee for another year is appointed some member of that committee should be a resident of the city of Madison.

Various excursion plans were discussed in connection with the summer meeting. A paper was then read by Mr. Alexander Dow, of Michigan, on "Electric Lighting for Profit."

MR. THAYER: I would like to ask Mr. Dow one question: In a large number of the smaller plants in towns of from 3,000 to 8,000 inhabitants, we find a combination of alternating and direct current series arcs. How would you recommend to handle a power load, by installation of direct current plant or going right ahead on alternate current lines?

MR. DOW: If you have a plant of that kind you are in the hole. I will not say whether you are to blame for being in that hole, but if you can get after the man who put you in—mark him down as not knowing his business or as being over-anxious to sell you the plant. How can you get out? I cannot recommend now any general prescription. There are two good methods of establishing a new plant or reorganizing an old plant, one is the so-called monocyclic system, which is a good system, and you can get arcs to run from it nicely—the new enclosed arcs do nicely on it—and it is for the general class of country towns and attendants a very satisfactory kind of a plant. Only do not make the mistake of putting in 2,200 volts if a little more copper will let you out with 1,100. You will have about three times as much trouble with wires and nine times the trouble with lightning with the higher pressure than you would if you stayed at the lower pressure.

The other plant is open to anybody, there being no patent in force, the 240-volt distribution. It is highly satisfactory. The unsteadiest kind of a power load is an elevator, but my station is successfully handling elevators during the daytime three miles from the station. We give bad lighting in the daytime, but the lighting from dusk to 11 o'clock is very good. If you can tell your customers plainly that the current will be on in the daytime, and that they should take what they get in the daytime and be thankful, and tell them that motors will run steady if the load is steady, they will be satisfied, and you can cover a tremendous amount of territory with your copper; only see that the two loads do not interfere. In most cases they do not interfere. Spend enough money for copper to begin with. That means, of course, no dividends for two or three years, and the man who sells the goods to you should say: "See here, are you willing to see this thing grow up until there is enough business to pay interest on the copper, or do you wish to begin to cash in your chips right away? If you do, you had better try the alternating system; but if you want a profit by and by with a pretty sure thing of it, try the other." The direct current system, 220 to 240 volts, has not yet been properly exploited, and I think it is the one that will cover the most small towns that my friend has spoken of. Outside of that is the monocyclic system, which is very satisfactory, and I would speak of it even more freely if it were not a system controlled by one company.

The subject of Municipal Ownership was taken up and discussed in executive session.

---

[1] See page 111.

The president appointed a committee on location of summer meetings, and the meeting adjourned until the following morning.

THURSDAY SESSIONS.

At the Thursday morning session LIEUT. FRANCIS A. BADT, of Illinois, made an address on "Topics of Interest to Central Station Men."

MR. W. H. EDGAR then addressed the meeting on the subject of "Physical and Chemical Properties of Volatile Oils in Boilers." The discussion which followed brought out some valuable points on boiler incrustations.

MR. DE LAND, of Chicago, read a paper written by Mr. John C. McWynn, of Chicago, on the subject of "Practice of Theory."

MR. JOHN E. RANDALL, of St. Louis, then presented a paper on "Present Efficiency of Incandescent Lamps."

The afternoon session was devoted to a discussion of a paper by PROF. R. B. OWENS, of the University of Nebraska, on "Electricity in Municipal Engineering," and a paper by MR. FRED De LAND on "Municipal Socialism." A very interesting discussion followed which was practically a continuation of the discussion begun by Mr. Dow, of Detroit, on the previous day, by Messrs. Norcross, Livermore, Thayer, Doherty, Bean, Thorpe, Pearce, Debell, Dee, De Land and Prof. Jackson, who gave valuable suggestions on the subject of depreciation and on the training of central station men. The committee on midsummer meeting then presented their report, recommending that the association do not hold a summer meeting in 1898. The report was accepted, and committee discharged. A committee of five was appointed to consider the advisability of holding a midsummer meeting and report before April 1, 1898.

The president and secretary were appointed to represent the association at the next meeting of the N. E. L. A. at Chicago.

The association met for routine business on Friday morning and then adjourned sine die.

Convention Notes and Exhibits.

THE CROCKER-WHEELER ELECTRIC COMPANY was represented by their Western manager, Mr. Julian Roe.

MR. H. J. GILLE, of the Chicago office of the Washburn & Moen Manufacturing Company, had a pleasant word for every one.

MR. A. J. STAHL, of the Yaryan system of steam heating, La Porte, Ind., was on hand busily expounding the virtues of his system to central station managers.

J. C. WORMLY occupied parlor 5, which was thronged continuously with his many friends. He exhibited a full line of Wormly & Shelby incandescent lamps ranging in voltage from 45 to 220 volts, and up to 50 candle power; also an assortment of miniature lamps from 2 volts upwards and 1-5 candle power upwards. In the rear of the parlor a neat switchboard was arranged, showing various styles of lamps. The filament exhibit consisted of squirted cellulose in the liquid form, threads before and after drying, carbonized and mounted, treated. There was also an exhibit of cut filaments made exclusively by Prof. A. A. Chaillet, technical manager of the Shelby Electric Company, Shelby, O.

MR. W. L. CHURCH, general manager of the lighting department of Milwaukee Lighting and Railway Company, busied himself getting the "boys" in line to attend a local theatre; about 100 took advantage of the opportunity and the entertainment was hugely enjoyed.

THE DEARBORN DRUG AND CHEMICAL COMPANY were represented by Mr. Chas. S. Kehler and Mr. W. H. Edgar, proprietor, who made many new friends.

SARGENT & LUNDY, engineers, Chicago, were ably represented by Mr. T. E. D. Richie, who expounded the qualities of C & C dynamos and motors, Fort Wayne incandescent lamps and Paragon fan motors.

THE EXHIBIT of the People's Electric Company, Madison, Wis., was in charge of F. H. Ford and C. W. Bacon. Among the many specialties which they showed were "Northern" generators and motors in operation, of which they are general selling agents; the Ritter soldering iron, of their own manufacture; "Enamelac" insulating paint, Peerless armature compound, "Perfection" dynamo brushes; "Grimshaw" and "Raven Core" wire, O. K. dry batteries, "Fagan" cutout, and various other specialties.

MR. W. W. LOW, the genial and energetic president of the Electric Appliance Company, was kept busy greeting his many friends in the trade.

THE CENTRAL ELECTRIC COMPANY, of Chicago, occupied parlor 6. They interested and entertained many friends with the latest improved Edison phonograph. Their interests were looked after by Chas. E. Brown, secretary, and Mr. W. P. Upham.

WESTERN ELECTRIC COMPANY, Chicago, were represented by Mr. H. L. Tucker, Thos. G. Grier and A. M. Little. They exhibited a full line of beautiful half-tones of desk and ceiling fans for direct and alternate current and the W. E. enclosed arc lamp. A pretty announcement was distributed which stated that the company are now headquarters for all sizes of Okonite wires and cables as well as Okonite and Manson Tape.

BRYANT ELECTRIC COMPANY, Chicago, was represented by Edward R. Grier, whose numerous friends gave him a hearty greeting.

McGILL & POMEROY, the two specialty stars, dropped in on the convention Wednesday; they extended the glad hand to their many friends.

MYSENBERG & BADT, Chicago, had a pretty exhibit of Hardy incandescent lamps, including the new 220-volt lamp; arc lamp hanger boards, Helios enclosed arc lamps, etc. Prof. F. B. Badt and R. F. Schuchardt were in attendance.

WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, had a neat exhibit of a Tesla two-phase motor and a new high voltage switchboard, both of which commanded great attention. The exhibit was in charge of W. H. Whiteside, Chicago representative, and Mr. J. E. Rugg, of Pittsburg.

THE interests of the Safety Insulated Wire and Cable Company were looked after by Mr. M. B. Austin, of Chicago.

BRYAN-MARSH COMPANY, who occupied parlor 12, showed a novel and interesting product, a new double-filament lamp, 110 to 220 volts. For the first time at a convention was exhibited a spark coil for the purpose of illustrating the manner of testing the vacuum of lamps. Many central station men were interested in ascertaining that they could at a small expense test the vacuum of their own lamps and not depend upon the claims made by manufacturers. Converse D. Marsh was among the longest dinstance visitors, having come from New York for the sole purpose of attending the convention. Mr. Jos. M. Hill, the Western manager, had charge of the exhibit.

VITRO-CHROME CHEMICAL COMPANY, Milwaukee, occupied parlor 8, showing a handsome switchboard with an assortment of colored incandescent lamps burning. They claim their colored lamps will withstand severe outdoor weather without affecting the colors which are dipped (but not collodion). Their zero frost lamp attracted much attention.

THE ELECTRIC SUPPLY COMPANY, of Madison, Wis., was represented by F. L. Stagg, secretary and treasurer, and L. W. Buch, president.

THE ELECTRIC STORAGE BATTERY COMPANY was ably represented by Mr. F. H. Clark, the Chicago manager, and R. B. Daggett, one of the company's engineers.

MR. A. G. CLAUSEN, chief electrician of the Goodrich Transportation Company, took a great interest in the proceedings of the convention.

CHAS. E. GREGORY COMPANY was represented by their popular president, Mr. A. Louis Kuehmstead, a description of whose splendid new quarters will be found in another column.

CHAS. E. GREGORY was on hand in the interest of the Elliptical Carbon Company, of Chicago.

CRANE COMPANY had Mr. C. H. Hurd on hand for information and circulars.

WAGNER ELECTRIC AND MANUFACTURING COMPANY, St. Louis, had a splendid exhibit of two-phase

motors showing their latest type and presenting some novel features. A full line of transformers and switches was also shown, as well as their 15 h. p. generator. All this apparatus as usual was of admirable design and beautiful workmanship. Mr. A. H. Abadie was in charge and met with a very cordial and hearty reception, being busy besides in answering inquiries after apparatus.

MR. T. R. MERCEIN'S efforts have assisted the convention materially in making it a great success, and he has made a host of new friends.

MR. JAS. F. CUMMINGS, Amorite, Pittsburg, was late in arriving, but he was none the less welcome. No electric light convention seems complete without "Jim." His friends, ever solicitous of his personal comfort, had provided for his coming; a large keg of Milwaukee's best had been placed at the foot of his bed. On the keg was a masterpiece of poesy.

THE FORT WAYNE ELECTRIC COMPANY had a very interesting exhibit of enclosed arc lamps and meters, all in operation. The new Duncan wattmeter has met with great success and has several very interesting and novel features. A very ingenious device is used in this meter for balancing the friction of the bearings so that it is possible to make meters of even 1,000-light capacity that will start on one 16-candle-power lamp. This device can also be used to compensate for small differences in voltage and also to overcome the tendency to creep if installed in a place where there is vibration. The jeweled lower bearing in this meter is supported on a spring which saves many jewels from being broken in installing. This meter is claimed to be absolutely accurate on all loads and all sizes from 1 to 100 lights, will register on a 4-candle-power lamp and any meter up to 1,000 lights capacity will start on one 16-candle-power lamp. Several types of enclosed arc lamps were shown in operation, including 110 and 220-volt D. C. lamps, and A. C. lamps. The 220-volt D. C. lamp is designed as are all other types for that matter to burn singly on their respective circuits. The A. C. lamps are built for any frequency and are operated either from a regular transformer with an economy coil in the lamp or from their well-known special arc lamp transformer without any resistance or economy coil in the circuit. This latter method of operating these lamps is more efficient than any other as practically all the energy in the lamp circuit is expended in the arc itself. These lamps are ornamental in design and furnished in several finishes. The Fort Wayne Electric Corporation were represented by Mr. E. L. Draffen, of Chicago, and Mr. Thos. Duncan and Mr. F. S. Hunting, of Fort Wayne. Mr. C. G. Guild, manager of the Jenney E. L. & P. Co., Fort Wayne, Ind., was also with the Fort Wayne delegation.

THE COLUMBIA INCANDESCENT LAMP COMPANY, St. Louis, was represented by Secretary and Treasurer H. C. Garrison, also by J. E. Randall, and Geo. P. Rix, manager of the Chicago office of the company. Mr. Garrison showed a line of lamps representing the different styles made by the Columbia Company, also a number of 220-volt lamps. In addition to lamps the exhibit included material showing the different stages of the filament, the liquid in its original state, the threads before carbonization, the treated filaments ready to be sealed in, etc. A number of the original Goebel lamps were also shown and proved of much interest.

EVERYBODY calls George Learing "Uncle." E. R. Grier, the Western representative of the Bryant Electric Company, is the father of a bouncing boy and now George Learing is figuring whether he is an uncle to the boy or a granduncle. As the Western representative of the Hart Company and an adopted granduncle of the recent addition, he feels his dignity weigh heavily upon him.

A. C. FOSTER, of Foster & Lewis, Chicago, engineers and contractors, represented the Triumph Electric Company, of Cincinnati.

JAMES WOLFF, Chicago representative of the New York Insulating Wire Company, was on hand and frequently in evidence.

ROHN & MEYER, State agents of the Helios Electric Company, exhibited a full line of Helios lamps in charge of B. L. Burdick.

CHICAGO INSULATED WIRE COMPANY was represented by W. M. Smith.

SOME MEN are fortunate in the names they bear, but none so fortunate as the genial Ned Fox, the Western representative of the Phœnix Glass Company. Mr. Fox has made use of his name for an advance card by having a picture of a fox to represent him. His earlier cards had a poor, lean-looking animal, but his most recent card has a sleek, fat, well-dressed fox, showing how well he has prospered. Some day you will see the card; then will shortly follow the portly form of everybody's friend—Ned Fox. He was at the Milwaukee convention.

THE ELECTRICAL PRESS was, as usual, well represented, as follows: Frank E. Perry, R. J. Parvin, J. B. O'Hara, "Western Electrician"; C. E. Kammeyer, "Electrical Review"; Fred de Land, "Electrical Engineering"; W. R. C. Smith, "American Electrician"; J. V. S. Church, "Electrical World"; E. L. Powers, C. E. Lukens, "American Electrical Directory"; A. C. Shaw, W. J. MacConnell, "The Electrical Engineer."

THE AMERICAN RHEOSTAT COMPANY'S exhibit consisted of one ½-horse-power 110-volt, one 5-horse-power 110-volt, one 7½-horse-power 110-volt automatic starter, and the front of a 100-horse-power 110-volt automatic starter, one 5-horse-power 220-volt speed controller, one 40-kilowatt 110-volt rear of switchboard field rheostat, one 3-kilowatt 115-volt wall type field rheostat, one 50-horse-power 220-volt Perfection starter, one front for a 20-horse-power 220-volt Perfection starter, one controller for sewing machine work, and one 10-horse-power 220-volt reversible elevator controller. F. R. Bacon, president, and J. G. Hickox, treasurer, of the company, were in attendance.

Armour Institute of Technology—W. H. Merrill on Fire Hazards.

MR. WILLIAM H. MERRILL, JR., electrician for the National Board of Fire Underwriters, delivered a lecture on Electrical Fire Hazards to the students of Armour Institute of Technology, Jan. 18. He divided the fire risks into eight classes, as follows: 1. Crosses between ærial wires of different systems. 2. Grounds and short circuits on electric light and power systems. 3. Wooden-based devices. 4. Transformer breakdowns. 5. Sparks from arc lamps. 6. Poor contacts and connections. 7. Heating effects of incandescent lamps. 8. Miscellaneous troubles from (a) cutouts; (b) switches; (c) rheostats; (d) motors and dynamos.

He recommended that transmission circuits, and even isolated plants, especially where the conductors pass from one building to another near by, should be put in underground circuits, unless there are good economic reasons for overhead construction. If this practice becomes general, fires of electrical origin will be much less numerous than at present, and a great many troubles which are destructive to apparatus will be avoided. He emphasized the danger of loose contacts, joints or connections when placed near inflammable substances, such as wood or fiber insulation.

These remarks were strikingly illustrated by numerous examples which had been collected by the inspectors. The necessity for some adequate earthing device to protect the secondary of the transformer from the primary e. m. f. was pointed out, and certain recent pieces of apparatus to accomplish this were described. He believed that the attempt to prevent the primary from short-circuiting with the secondary could not be reliably accomplished by increasing the thickness and character of the insulation. The fire hazard with transformers is very great when high electromotive forces accidentally get in the primary coil. In one instance, lightning burned through to the secondary coil and punctured the gas pipe in four or five chandeliers just at the insulating joint, and ignited the escaping gas, thus starting four or five simultaneous fires in the house.

Manufacturers to Meet.

The third annual convention of the National Association of Manufacturers will be held in Masonic Temple, corner Sixth avenue and Twenty-third street, on Jan. 25, 26 and 27. There will be three sessions on the first two dates and two on the last. Reports of officers and committees will be presented on Tuesday afternoon.

LEGAL NOTES

Decision as to Motor Suspension.

Sprague Elec. Ry. & Motor Co. *vs.* Union Ry. Co. and Walker Mfg. Co.

JUDGE WHEELER in the U. S. Circuit Court for the Southern District of New York has just handed down a decision in favor of the complainants in this case, under the Sprague patent No. 324,892, of August 25, 1885, for an electric railway motor consisting of a field magnet journaled on the axle of the driving wheels at one end, and hung upon a spring from the truck or the car body, at the other; and carrying the armature shaft upon its pole pieces parallel with the shaft of the driving wheels, and connected to them by gearing. The claims in question were the second, sixth, and ninth. The court says: "The defendants' structures differ in some respects from those of the patent, but have all these parts working together in the same relation to each other, for the same purpose and producing the same result. They are altered by the addition of a joint in the motor, and of another spring to help carry it, but not by dispensing with any of the parts; they are improved upon but not departed from. The defendants' improvements are not made independent of, and clear from, Sprague's but upon his; and his patent appears to be infringed by this taking of his invention to improve upon." The Sprague Company's patents of that time are, of course, now owned by the General Electric Company, which has in reality brought the suit. For the plaintiffs F. H. Betts appeared, and C. E. Mitchell and H. B. Brownell for the defendants.

Recent Street Railway Decisions.

Running an electric car at an unusually rapid rate over a much frequented crossing, when the usual rate was from 12 to 14 miles per hour, was held, in Evansville St. R. R. Co. vs. Gentry (Ind.) 37 L. R. A. 378, to be such negligence as constitutes little less than wanton and reckless disregard of human life. But it is held that some slight proof at least of a want of contributory negligence was required in case of a man killed by the car and found about 45 feet from the crossing, at which he had stepped from another car.

The exemption of a street railway from a license tax is held, in Springfield vs. Smith (Mo.) 37 L. R. A. 446, not to be granted by a mere grant of the privilege of operating the road for a term of years, if the license tax is imposed under statutory authority, although for revenue purposes, and not simply for police regulation.

Driving a fire truck to a fire so rapidly that on approaching an electric street car track it is impossible to stop in time to avoid a probable collision is held, in Garrity vs. Detroit Citizens' St. R. R. Co. (Mich.) 37 L. R. A. 529, to constitute negligence on the part of the driver, although by the city ordinance he has the right of way.

A New York State Telephone Rates-Reduction Bill.

The first telephone rates-reduction bill of the session has been introduced by Assemblyman Cain (Dem.), of Brooklyn. It provides that six months after the passage of the act the charge for the annual or monthly use of a telephonic communication, both by day and night, together with such instruments and electrical apparatus as shall be necessary to transmit vocal messages between the patrons or subscribers of any telephone company within the limits of this State (which charge and price shall be pro rata for shorter periods) shall be, in cities of one million inhabitants and over not to exceed a rate of $85 per annum; cities of 500,000 and less than a million, not to exceed $75; in cities of 500,000 and less than a million, habitants, not to exceed $48; in cities of 20,000 and less than 100,000, not to exceed $36; in places of 8,000 and less than 20,000 inhabitants, not to exceed $30, and in all cities and places of less than 8,000 not to exceed $27. The population as ascertained in the United States census of 1890 shall be the basis upon which the rates shall be fixed, and when the rates have been so fixed they shall not be thereafter increased by reason of an increase of population in any city or place in the State.

The charges at public pay stations in any place shall not exceed ten cents for the first five minutes after connection is made, and five cents for each five minutes or part of five minutes thereafter. No yearly or monthly patron or subscriber having and paying for a telephone at his own home or office shall be charged for the use of a telephone at a public pay station, when used by him or his employees for communicating with his own home or office, and all subscribers shall be furnished with certificates entitling them to such free use of pay stations.

The Comptroller, Attorney-General, and State Engineer and Surveyor, within thirty days after the passage of the act, shall meet at Albany for the purpose of carrying into effect its provisions, and thereafter at the same place once each month, and at such other times and places as the purposes of the act may require. They shall investigate all complaints, and in their discretion if a company is losing money or in any financial distress may increase the rate.

MARRIED

Hull—Linke.

J. F. Hull, superintendent of the Polk County, Missouri, Telephone Line, and Miss Flora Linke, both of Humansville, Mo., were married recently over the telephone wire. The groom was at Bolivar, Mo., while the bride was at Humansville. There was a minister at each end of the wire with the required number of witnesses. All parties were acquainted with one another and recognized the various voices, so that the witnesses are prepared to swear, if the question is ever raised, that they know that the ceremony was properly performed.

OBITUARY

Oliver B. Shallenberger.

IT is with deep regret we record the death at Colorado Springs, Colo., of Mr. O. B. Shallenberger, who had sought health in that section of the country for some time past, on account of the weakness of his lungs. Although barely 38, he had done much to make himself remembered in the development of electric light and power in America. He was born at Rochester, Pa., and at the age of 17 entered the United States Naval Academy at Annapolis, where he graduated in 1881. After two years' active service afloat, he resigned his commission, and became engaged in the experimental work of the electrical department of the Union Switch and Signal Company, which at that time had undertaken the manufacture of the Stanley continuous current apparatus. When the Westinghouse Electric Company was organized in January, 1886, and the great development in alternating current came, Mr. Shallenberger was appointed chief electrician. He held this position with much credit until his health broke down, four or five years ago, and he was compelled to seek the dry air of Colorado. During his active career he made numerous inventions, one of which was the beautiful Shallenberger meter. He became a member of the American Institute of Electrical Engineers in 1888. The body of Mr. Shallenberger has been brought East, and the funeral will take place at Rochester, Pa., at 10 a. m. on Saturday, January 29.

MR. B. BUTTERWORTH, U. S. Commissioner of Patents, died last week in the South, whither he had gone in search of health. He was born in 1822, and had been active in national politics as a Republican all his life. He served also as Commissioner of Patents in the eighties.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued January 4, 1898.

Alarms and Signals:—

ALARM CLOCK ATTACHMENT. P. C. Howe, Boston, Mass., 596,680. Filed April 15, 1897. Comprises an alarm clock, operated by a thermostat for releasing the alarm train of the clock and of a circuit-breaker operated by alarm-train.

ELECTRIC SIGNALING APPARATUS. F. B. Herzog, New York, 596,774. Filed May 31, 1895. Annunciator.

EXHIBIT PROTECTOR. H. J. Olney, Cedar Rapids, Iowa, 596,824. Filed March 13, 1897. Comprises a pneumatic tube located between two platforms and an alarm mechanism actuated by the movement of the diaphragm of the tube.

ELECTRIC CLOCK. F. Richard, Lynn, Mass., 596,943. Filed Aug. 21, 1896. Details of construction.

AUTOMATIC TEMPERATURE REGULATOR. A. A. Boss, Detroit, Mich., 596,955. Filed March 31, 1897. Means for actuating the draft controlling mechanism of heaters, so that the dampers of the heater may be automatically opened and closed.

Batteries, Primary:—

VOLTAIC BATTERY. H. E. De Rufz De Lavison, Neuilly-Sur-Seine, France, 596,791. Filed May 28, 1897. The depolarization of the negative electrode is effected by heat.

Conductors, Conduits and Insulators:—

PRESS FOR MAKING INSULATORS. Henry M. Brookfield, New York, N. Y., 596,651. Details of construction.

PRESS FOR MAKING INSULATORS. Henry M. Brookfield, New York, and S. Krits, Brooklyn, N. Y., 596,652. Filed January 2, 1897. Similar to above.

PRESS FOR MAKING INSULATORS. S. Kribs, Brooklyn, N. Y., 596,682, Filed January 30, 1897. Similar to above.

Distribution:—

CONVERTER FOR MONOPHASE CURRENTS. A. Blondel and G. Sautter, Paris, France, 596,567. Filed June 27, 1895. Comprises an armature having a primary and a secondary winding, surrounded by a closed magnetic frame, a tertiary winding relatively stationary with reference to the magnetic frame, and a quarternary exciting winding.

Dynamos and Motors:—

ELECTRIC FAN. O. F. Conklin, Springfield, Ohio, 596,483. Filed June 17, 1897. Ceiling fan. Details of construction.

Electro-Metallurgy:—

APPARATUS FOR EXTRACTING GOLD, ETC., FROM DRY CRUSHED ORES. E. L. Oppermann, London, Eng., 596,535. Filed March 11, 1897. Mercury vapor and steam are blown under pressure upon the crushed ore and the metal is extracted magnetically.

PROCESS OF AND APPARATUS FOR UTILIZING WASTE PRODUCTS OF BLAST FURNACES. H. L. Hartenstein, Bellaire, Ohio, 596,704. Filed October 27, 1896. Consists in mixing slag with carbonaceous material. Injecting a reducing gas and subjecting the whole to the action of an electric current.

PROCESS OF UTILIZING WASTE PRODUCTS OF BLAST FURNACES. H. L. Hartenstein, Bellaire, Ohio, 596,705. Filed October 27, 1896. Similar to above.

MAGNETIC ORE SEPARATOR. L. G. Rowand, Camden, N. J., 596,719. Filed April 16, 1897. Comprises a conveyer belt carrying the material to be treated, a discharging belt passing over and at an angle with the conveyer belt, a magnet above the belts at the crossing point and extending above the discharge-belt beyond the conveyer belt.

MAGNETIC ORE SEPARATOR. L. G. Rowand, Camden, N. J., 596,720. Filed April 15, 1897. Similar to above.

PROCESS OF UTILIZING WASTE PRODUCTS OF BLAST FURNACES. H. L. Hartenstein, Bellaire, O., 596,749. Filed October 27, 1896. Similar to 596,705.

Lamps and Appurtenances:—

MEANS FOR VARYING CANDLE POWER OF INCANDESCENT ELECTRIC LAMPS. C. E. Felch, Natick, Mass., 596,582. Filed June 21, 1897. Includes in circuit between the line and the lamp filament a permeable resistance medium adapted to be entered to a greater or less depth by an electrode also included in the circuit.

PROCESS OF PRODUCING HIGH VACUUMS. E. F. Dwyer, Lynn, Mass., 596,654. Filed October 26, 1897. Consists in pumping out the main portion of the gases, heating the remaining gas while continuing the pumping, driving off occluded gases, and producing a condensable gas by an electric current passed through a circuit within the receptacle, and finally sealing.

SUPPORT FOR ELECTRIC LAMPS. O. C. White, Worcester, Mass., 596,729. Filed February 16, 1897. A support, a pipe pivotally connected thereto, a ball secured to the end of the pipe, an electric lamp fixture, a ball connected thereto, yoke pieces, and a single clamping device for adjustably clamping the pieces into engagement with the balls.

Miscellaneous:—

ELECTRIC OVEN. L. E. Custer, Dayton, Ohio, 596,696. Filed March 16, 1896. Details of construction.

SAFETY MAGNET-BRAKE. John D. Ihlder, Yonkers, N. Y., 596,514. Filed September 21, 1896. An automatic safety brake device, combined with a mechanical brake which operates to set the safety brake.

COMPOUND BRAKE FOR ELECTRIC ELEVATORS. John D. Ihlder, Yonkers, N. Y., 596,513. Filed September 14, 1896. Comprises a spring-compression device connected with the brake; a direct, positively-acting device, also connected with the brake, and means for operating both devices.

APPARATUS FOR STERILIZING AND PURIFYING WATER. N. Van Der Sleen, Haarlem, and A. Schneller, Netherlands, 596,917. Filed August 31, 1895. Comprises a vessel having in its bottom an inlet for the ozone employed, nozzles adapted to atomize the water to be sterilized, the nozzles being arranged so as to converge toward each other, as well as toward the inlet for the ozone.

Railways and Appliances:—

SUBTERRANEAN ELECTRIC CONDUIT. W. D. M. Howard, Redwood City, Cal., 596,812. Filed June 18, 1897. Underground railway conduit system.

ELECTRIC CABLE FOR PROPULSION OF VEHICLES. A. Norman, Toronto, Canada, 596,907. Filed July 8, 1896. Combines the sectional working conductors with the supply conductor, which forms a coat of protection for the supply conductor.

TROLLEY GUARD. H. J. Vogler and A. Flores, San Antonio, Tex., 596,926. Filed Oct. 16, 1897 Consists of a pair of yielding guards with their springs arranged one on each side of the trolley wheel, which guards hold the wheel on the wire, but yield and pass under the cross supporting wires.

Regulation:—

AUTOMATIC POTENTIAL REGULATOR FOR DYNAMOS. A. A. and P. S. Tirrill, Groveton, N. H., 596,923. Filed May 1, 1897. Details of construction.

Switches, Cut-Outs, Rheostats, Etc.:—

ELECTRIC SWITCH. W. S. Hill, Hyde Park, Mass., 596,506. Filed May 1, 1896. Means for securing the blades of wrought-copper, yoke and intermediate insulation, or where only one blade is used, the handle and insulation to the end of the blade.

AUTOMATIC STOP MOTION SNAP SWITCH. J. D. Ihlder, Yonkers, N. Y., 596,512. Filed August 11, 1896. Comprises a switch and shaft for operating it, a mutilated gear connected to the shaft, an internal gear, arranged to engage the mutilated gear and a support for the internal gear.

STARTING BOX FOR ELECTRIC MOTORS. J. D. Ihlder, Yonkers, N. Y., 596,515. Filed October 11, 1897. Compries switch and means for moving it, automatic means controlling the shaft, comprising a quick operating device for moving the shaft to operate the switch, and a slow moving device for controlling the movements of the quick moving device.

Telephones:—

TELEPHONE. Wm. Gray, Hartford, Conn., 596,496. Filed April 20, 1896. Embodies a sound passage to the transmitter-diaphragm, a signal box and a tubular connection between the signal box and transmitter case, forming a signal passage, having a deflector located outside of and with its outer surface flush with the wall of the sound passage.

SIGNALING APPARATUS FOR TELEPHONE SYSTEMS. F. J. Holmes, Cleveland, Ohio, 596,509. Filed March 25, 1896. A transmitting and receiving apparatus for code signals for use in connection with telephone or telegraph systems.

SUPERVISORY SIGNAL FOR TELEPHONE SWITCHBOARDS. F. R. McBerty, Downer's Grove, Ill., 596,609. Filed October 26, 1896. Comprises an electro-magnet adapted to prevent the display of the indicator when excited, and a mechanical device in the plug socket acting upon the indicator to prevent its display when the plug is present in the socket.

SIGNALING SYSTEM FOR TELEPHONE TRUNK LINES. F. R. McBerty, Downer's Grove, Ill., 596,610. Filed November 24, 1896. A device for causing the act of removing a connection at one of the switchboards, to display the signal at the other switchboard calling for a disconnection of the trunk line.

PLUG AND SPRING JACK FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 596,625. Filed November 29, 1895. Combines a spring jack having a tubular contact-thimble and a contact spring with a plug having a contact-ring for the contact spring, and an insulating ring of larger diameter than the contact ring placed before the latter, whereby it is prevented from touching the contact-thimble.

SPRING JACK FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 596,626. Filed May 14, 1896. Details of construction.

ANNUNCIATOR FOR TELEPHONE LINES. C. E. Scribner, Chicago, Ill., 596,627. Filed May 14, 1896. A momentary signaling current from the sub-station causes the display of the indicator and at the same time closes a circuit of a local source of current through the annunciator to insure its continuous excitement until connection is made with the line.

SUPERVISORY SIGNAL FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 596,628. Filed November 16, 1896. Details of construction.

TESTING APPARATUS FOR MULTIPLE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 596,629. Filed December 8, 1896. Details of construction.

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 596,630. Filed December 8, 1896. Contrivance for controlling subsidiary signals associated with connecting plugs in a telephone switchboard.

APPARATUS FOR TELEPHONES. F. B. Cook, Chicago, Ill., 596,806. Filed March 17, 1896. Magneto calling apparatus.

TELEPHONE TRANSMITTER. D. A. Fleming, Indiana, Pa., 596,808. Filed April 12, 1897. Is provided with a curved tube open toward the diaphragm and mounted to turn, balls arranged in the channel, the latter being inclined relatively to the axis of rotation.

TELEPHONE TRANSMITTER. J. H. Spencer and M. S. Keyes, New York, 596,834. Filed January 14, 1897. Is provided with buttons, and granulated German silver held between the buttons.

TELEPHONE SWITCH PLUG. F. B. Cook, Chicago, Ill., 596,850. Filed January 4, 1896. Details of construction.

TELEPHONE APPARATUS. F. B. Cook, Chicago, Ill., 596,851. Filed November 30, 1894. Comprises a combined ringing and listening key.

SWITCH FOR TELEPHONE CIRCUITS. F. B. Cook, Chicago, Ill., 596,852. Filed March 25, 1895. A telephone switch having a pair of crossed springs adapted for contacting at two points on the opposite sides of each, and means for operating the springs whereby to establish or disestablish the contacts.

Classified Digest of U. S. Electrical Patents issued January 11, 1898.

Alarms and Signals:—

ALARM DEVICE. W. E. Downing, Des Plaines, Ill., 596,989. Filed April 20, 1897. Adapted especially to greenhouses to indicate that the temperature of the heating apparatus has fallen below a predetermined degree.

FIRE ALARM. G. A. Townsend, Utica, N. Y., 597,128. Filed May 18, 1897. A circuit is closed by a normally retained spring released by solder melting when the temperature reaches a predetermined point.

Batteries :—

PRIMARY BATTERY. C. J. and H. C. Hubbell, Scranton, Pa., 597,239. Filed May 8, 1897. Embodies a negative element having a central vertical cylindrical enlargement provided at its lower end with a depending lug, in combination with a metallic ring surrounding the lug.

Dynamos and Motors :—

DYNAMO ELECTRIC MACHINE. J. Sohlman, Wiborg, Finland, 597,090. Filed May 22, 1897. Alternating current generator. Details of construction.

STATIC INDUCTION ELECTRIC GENERATOR. A. L. Bogart, Jamaica, N. Y., 597,137. Filed May 5, 1897. Comprises a cylinder made of insulating material, a removable plug therefor, of similar material, metallic contact springs carried by the plug and adapted to contact with the stationary member of the device.

Electro-Therapeutics :—

GRAPHITE RHEOSTAT. E. W. Jewell, Chicago, Ill., 597,002. Filed May 8, 1897. Adapted for use in electro-therapeutical operations.

ELECTRIC TRANSFORMER. J. F. Gates, Pittsburg, Pa., 597,180. Filed January 29, 1897. For therapeutical work.

Lamps and Appurtenances :—

FILAMENT FOR INCANDESCENT LAMPS. E. F. Von Wilmowsky, Boston, Mass., 597,172. Filed September 3, 1896. A filament or conductor for incandescent lighting composed substantially of boron.

COMBINATION GAS AND ELECTRIC LIGHT FIXTURE. J. W. Parkin, Philadelphia, Pa., 597,244. Filed December 23, 1896. Details of construction.

Miscellaneous :—

MAIL-COLLECTION SYSTEM. D. A. Gray, Boston, Mass., 596,993. Filed June 3, 1897. Places the letter boxes in electrical connection with the post office, so that they cannot be opened excepting by operating the keyboard at the post office, which unlocks the box through the medium of electrically controlled locks.

PROCESS OF MAKING CALCIUM CARBIDS. J. E. Hewes, Philadelphia, Pa., 596,909. Filed March 16, 1897. Consists in mixing carbid-producing materials, and a flux containing manganese, and then subjecting the mass to the action of heat sufficient to effect reduction of both compounds.

AUTOMATIC STOPPING MECHANISM FOR ENGINES. V. E. Hunter, Cleburne, Texas, 597,198. Filed June 24, 1897. Means adapted to co-operate with a moving belt, so that in the event of the belt becoming displaced from its pulleys the mechanism will operate to close the throttle valve.

ELECTRIC SEARING-PEN. Henry Green, Hartford, Conn., 597,373. Filed April 16, 1897. Comprises a handle; a cap incasing a resistance medium in which is embedded a searing pen passing through one end of the cap from which it is insulated.

Railways and Appliances :—

ELECTRIC RAILWAY CONDUIT SYSTEM. R. F. Thompson, Alexandria, La., 597,036. Filed July 13, 1897. Details of construction.

INSULATED TROLLEY HANGER. E. J. Cook, Cleveland, Ohio, 597,140. Filed December 2, 1897. Details of construction.

ELECTRIC RAILWAY MOTOR. C. J. Van Depoele, deceased, C. A. Coffin and A. Wahl, administrators, Lynn, Mass., 597,156. Filed June 11, 1890. Comprises a switching device adapted to change the circuit relation of the motors, and means for opening the circuit during such changes at a number of circuit breaking points in series, and independent of the points or contacts where the circuit changes are made.

AUTOMATIC TENDER FOR TROLLEY OPERATING ROPES. C. F. Wilson, Brooklyn, N. Y., 597,159. Filed October 1, 1896. Details of construction.

ELECTRIC RAILWAY. H. W. Libby, Boston, Mass., 597,202. Filed March 10, 1897. Means for propelling, heating and lighting railroad cars by electricity, and in means for telephoning from cars to any desired point.

TROLLEY GUARD. H. F. Hendricks and J. H. Denton, Philadelphia, Pa., 597,282. Filed September 12, 1896. Employs a secondary wheel having a wider groove and capable of lateral travel.

CURRENT COLLECTING MEANS FOR ELECTRIC RAILWAY VEHICLES. C. A. Terry, New York, 597,306. Filed September 17, 1896. A laterally extending contact device in which all of the engaging portion is rotatable.

CONTROLLER FOR ELECTRIC CARS. J. C. Henry, Denver, Colo., 597,374. Filed November 6, 1897. Comprises an electric motor having an armature and field magnet and a trolley having two contacts engaging with the supply-wire, and connected respectively with the armature and field magnet of the motor.

Regulation :—

METHOD OF REGULATING SPEED OF SERIES ELECTRIC MOTORS. H. F. Parshall, London, England, 597,018. Filed April 5, 1897. Employs a line circuit supplying the motor current at constant potential, and a source of electromotive force opposed to that of the line, in shunt to the field magnet circuit of the motor.

CONTROLLER FOR ELECTRIC MOTORS. C. S. Cook, Pittsburg, Pa., 597,265. Filed January 2, 1897. A starting, stopping and reversing switch for electric motor controllers, having two-part brushes for each pair of movable reversing contacts, the parts being being connected by a resistance.

Switches, Cut-Outs, Etc :—

MEANS FOR OPERATING ELECTRIC SWITCHES AND EXTINGUISHING SPARKS THEREOF. J. B. Knudson, Chicago, Ill., 597,150. Filed June 16, 1897. Employs an air-cylinder for blowing the sparks.

ADJUSTABLE SWITCHBOARD. H. H. and F. D. Walker, Philadelphia, Pa., 597,228. Filed September 23, 1897. Comprises a plurality of plates, wings attached to the latter and adapted to contact with each other in whatever position said plates may assume and means for making electrical connections to said wings.

Telephones :—

APPARATUS FOR STATING TIME AND NUMBER OF TELEPHONIC CONVERSATIONS. E. Kosanke, C. Fuhr and B. Krausse, Wilmersdorf, Germany, 597,003. Filed July 5, 1895. Employs a clock work mechanism adapted to be wound and released by the circuit closing and interrupting movements of the lever in the calling and speaking circuits.

TELEPHONE EXCHANGE SYSTEM. W. W. Dean, St. Louis, Mo., 597,052. Filed September 22, 1897. Provides automatic means jointly controlled by the operators and subscribers for including the calling generators in circuit with the signal receivers of the called stations.

TELEPHONE EXCHANGE SYSTEM. William W. Dean, St. Louis, Mo., 597,053. Filed September 22, 1897. Similar to above.

TELEPHONE SYSTEM. W. W. Dean, St. Louis, Mo., 597,054. Filed September 22, 1897. Similar to above.

CALLING DEVICE FOR TELEPHONE EXCHANGES. A. E. Keith and J. C. Erickson, Chicago, Ill., 597,062. Filed Aug. 20, 1896. Comprises a circuit breaker, a circuit changer for directing the current over different lines, a series of finger-holds, and a stop for automatically limiting the number of times that the changer may be operated.

TELEPHONE ATTACHMENT. P. J. Bose, Bremen, Germany, 597,213. Filed November 16, 1896. Adjustable device for holding telephone receivers.

THE STOCK MARKET

Improving Industrial Conditions.

When it is stated that general business shows an improvement of 10 per cent. above that of the corresponding period in the booming year of 1892, no further explanation is required of the strength of the stock market, a firmness that so far Cuban scares and political vagaries have done little to weaken. During the week 12,620 shares of Western Union were sold, closing at 90¼; 8,585 shares of General Electric around 35¼, and 758 shares of Bell telephone around 270. Among local lighting stocks, New York Edison distinguished itself by going up to 135, a record figure we believe for a security that grows more and more in favor.

REPORTS OF COMPANIES

Erie Telephone Company's Bonds.

E. C. Stanwood & Company, of Boston, have been offering for sale at 97 and accrued interest $1,000,000 of Erie Telegraph and Telephone Company 5 per cent. collateral trust sinking fund gold bonds, due July 1, 1926, being part of $2,000,000, of which $1,000,000 have been previously sold. Both the bonds and stock of the company are quoted at the New York Stock Exchange. The Erie Telegraph and Telephone Company in conjunction with the American Bell Telephone Company own and operate the subordinate corporations conducting the Bell telephone business in Cleveland, O., and in all of Minnesota, North and South Dakota, Texas and Arkansas, excepting only Duluth and the Black Hills district. The company have a capital stock of $4,800,000 upon which dividends have been paid continuously for 14 years. The issue of the bonds is to provide the Erie Company with capital for extensions of their system. The net income of the company for 1897 was $365,000, being more than double the amount of its total bonded interest.

CLOOS ELECTRIC ENGINEERING COMPANY has been formed at Milwaukee, Wis., by Jacob Cloos, H. R. King and E. A. Wurster, with a capital stock of $20,000.

METROPOLITAN ELECTRIC CONSTRUCTION COMPANY has been formed in this city with a capital stock of $50,000, by E. C. Platt, A. B. Chandler, E. H. Johnson, W. B. MacQuesten and others.

THE COLONIAL ELECTRIC CO., of New York, has been incorporated to furnish light, heat and power by means of electricity in Greater New York. The capital stock is $25,000, and the directors for the first year are: Garrett S. Odell and Orion H. Cheney, of New York, and Horace S. Andrews of Brooklyn.

TRADE NOTES & NOVELTIES

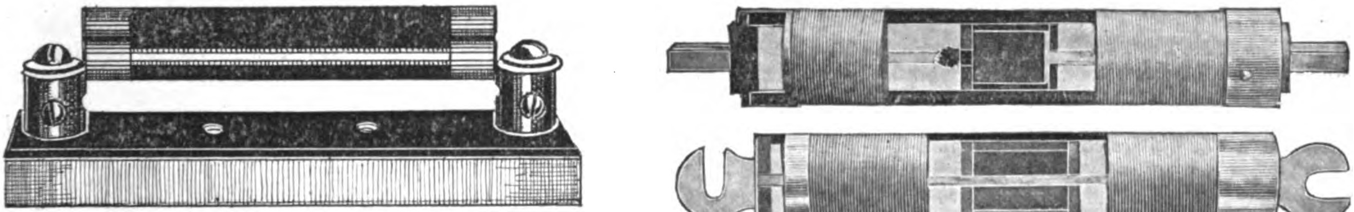
The Armington & Sims Company.

WE are glad to be able to announce the completion of the work for the full reorganization of the Armington & Sims' engine interests. For some time past steps to this end have been taken in Providence, and the results are most satisfactory, we understand, to all concerned. The new corporation is to be known as the Armington & Sims Company, and a number of well known men have become its officers. Mr. Julius Palmer, the president, is also president of the old National Bank, Providence; Mr. J. C. Church, secretary and treasurer, is a prominent business man in that city. The general manager, Mr. Fred. N. Bushnell, has been identified with the engine business for many years. For the last five years he has acted as the mechanical engineer for a number of large electrical interests, notably the Narragansett Electric Lighting Company.

It is gratifying to know that the new company starts out under the most favorable conditions, also, in the financial sense, having a capital of $150,000. It has already a number of orders for its 1898 pattern of engine, and is prepared to furnish promptly plans and specifications for engines of all sizes and for all purposes, including large direct-connected units, side-crank, high, medium and slow speed, etc. The company has an illustrated pamphlet now in press, "A Few Facts About Armington & Sims' Engines," which will shortly be ready, and which it will be glad to send to any one interested, particularly prospective customers.

The Cartwright Enclosed Air-tight Fuses.

THE Cartwright enclosed air-tight fuses are manufactured by the Shawmut Fuse Wire Company, of Boston, under license from the Goodhart Electric Company. In this instrument the fuse is so constructed that the wire melts within the central section of the tube and the heated air and gases formed thereby, forcing themselves to the outer or end sections, blow out the arc. This fuse can be used on any pressure less than 2200 volts. It will not maintain an arc between its terminals when short-circuited on the mains of a 2200-volt composite alternating dynamo.



FIGS. 1, 2 and 3.—THE CARTWRIGHT ENCLOSED FUSE.

The cutout consists of two parts; the base and tube. The base is made of the best quality of Monson slate, the tube is made of black or gray fiber. Fig. 1 represents the cutout complete. Fig. 2 represents the fuse with the central part of the case cut away to show the fuse-wire in the central air space and also the filling at each end. Fig 3 represents a 50-ampere fuse cut open after it had been short-circuited on a 500-volt circuit of 450-kilowatt capacity and it opened the circuit without noise or flash.

Owing to the peculiar construction of this enclosed safety fuse, a tube or case three inches long will open the circuit where the ordinary devices require more than twice that length operated under the same conditions and with a fuse of the same carrying capacity.

This fuse has a definite length, cannot come in contact with any foreign substances, and it will open the circuit in a pre-determined time on a given current in amperes.

Each fuse is marked the number of amperes it will carry indefinitely; it will melt on a 25 per cent. increase of current.

Porcelain Lined Outlet Boxes.

The porcelain lined outlet box has taken its place among the necessities of modern high grade interior wiring. It has sprung into prominence so rapidly that outside of the Metropolitan district it has not as yet seen much use, but thousands of these porcelain lined outlet boxes are going into the new buildings in New York City every month, and there are upwards of 100,000 already in use in that city alone. The Ward-Leonard Electric Company, who first gave these devices commercial prominence, are just issuing a 40-page catalogue, gotten up with their usual skill in catalogue work, and it is most astonishing to see the hundreds of different styles of outlet boxes, switch boxes, floor boxes, receptacle boxes, etc., which they list and illustrate both by scale drawing and half-tones.

The price of these porcelain lined boxes is now but a few cents in advance of the cost of the cast iron in the box, while the price of the first porcelain lined boxes used by C. O. Mailloux at Biltmore was about a dollar per box.

The Ward-Leonard Company have a capacity for turning out 3,000 of these boxes per day, and have by improved process so reduced the cost, that there is no longer any excuse for using the boxes having merely white paint as the insulation.

This new catalogue of the Ward-Leonard Company is the work of many months, and it is so complete and specific that it will prove a great assistance to the architects, consulting engineers and contractors in planning and executing interior conduit wiring.

Three Calendars.

THE NATIONAL CARBON COMPANY'S calendar is one that must prove very useful to the central station managers, as it bears on each of the twelve date slips the moonlight schedule for the respective months and it also gives the time of the sun's rising and setting. It is tastefully gotten up and on it appears an engraving showing the company's extensive works in Cleveland, Ohio.

THE BOSSERT ELECTRIC CONSTRUCTION COMPANY, Utica, N. Y., have distributed a very neatly engraved calendar on which are reproduced one of their ironclad panelboards and several styles of their split steel junction boxes. Split steel wall outlet and switch boxes have for some time been this company's specialty and they are to be congratulated on the ever-increasing popularity of their products.

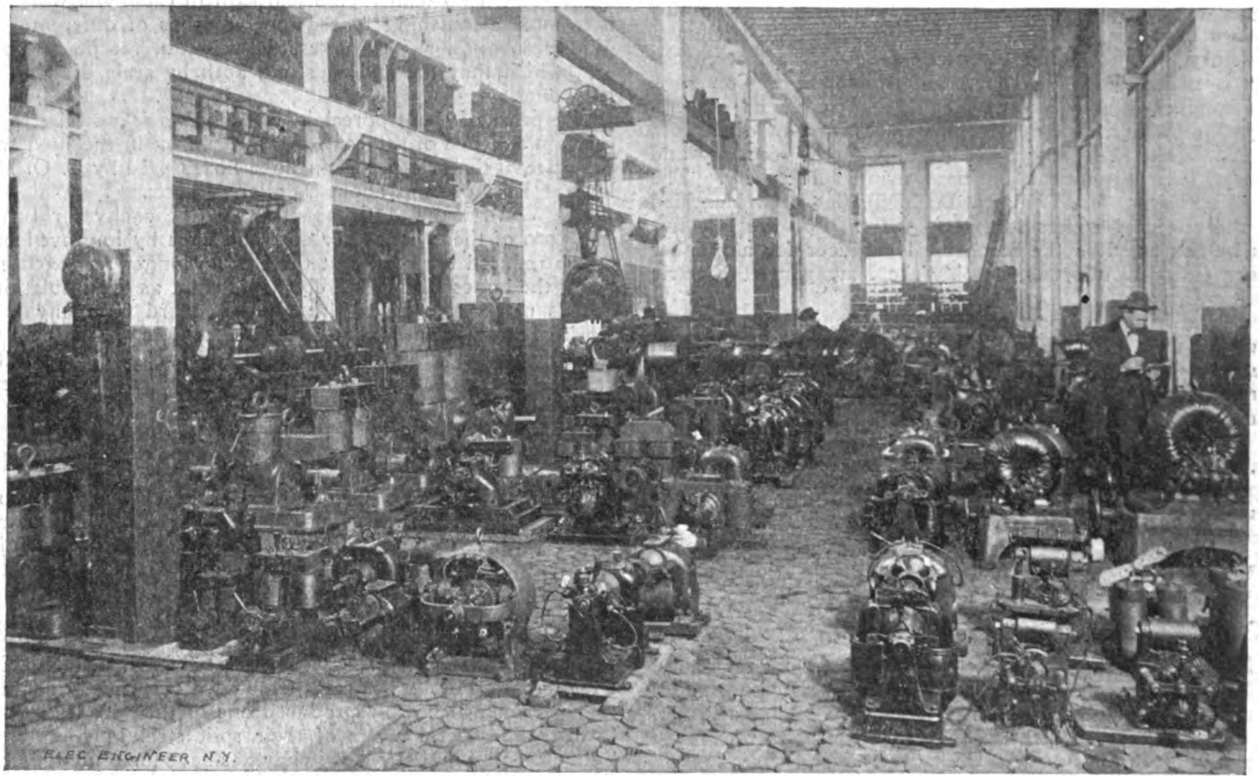
GENERAL ELECTRIC COMPANY have issued an extremely useful calendar with moonlight schedule. It is a good thing to have around the station.

ARMORITE INTERIOR CONDUIT is now, its makers assert, generally recognized by architects and contractors as the standard for all high grade interior work. This conduit, as it is now made, with the light steel wall and light lining is superior to the old style heavy conduit and is displacing entirely the old type of tubing. The Electric Appliance Co. are carrying a large stock of light wall steel armorite in Chicago and are doing a handsome business in it.

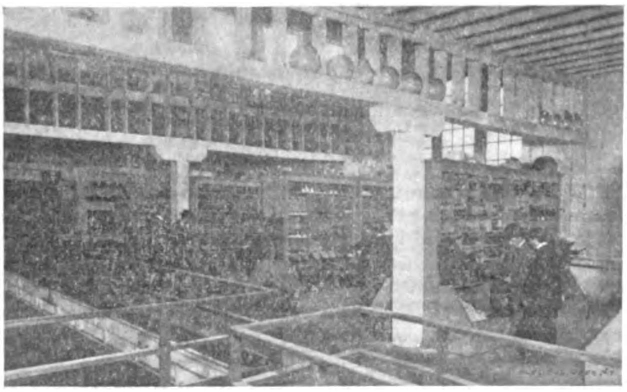
THE AMERICAN BATTERY COMPANY'S factory on Quincy street, Chicago, was completely gutted by fire on Jan. 15. Their entire stock was destroyed, but the energy of these people has been shown by the fact that they are now established in handsome new quarters at 174 South Clinton street, Chicago, occupying the entire floor and basement and are already in shape to take care of all orders. This company's loss was partially insured.

The Growth of Second Hand Business in Electrical Machinery—Chas. E. Gregory Co.

NOTHING better illustrates the fallacy of the statement that electricity is in its infancy than the proportions assumed by the business in second-hand dynamos, motors, arc lamps, meters, transformers and all the paraphernalia that are necessary in electric light and power work. A visit to the Charles E. Gregory Company establishment at Chicago, which is one of the largest second-hand electrical supply houses in the United States, will be a revelation to one who has not kept close track of this branch of the electrical business. The importance of a second-hand house in the electrical field is great, because it affords users of electrical machinery an opportunity to dispose of their "outgrown" apparatus to advantage, and many a small lighting plant where dollars come hard is glad to get the good machinery discarded by larger plants. The Gregory house started seven years ago with two employees and a small office. It now has 37 on the pay roll and the prospect that more will soon be necessary. They are now just comfortably settled in a well fitted up machine shop building, at 58 to 62 South Clinton street, and are in shape to handle their large business to advantage. If the reader pictures to himself a lot of disreputable looking apparatus before visiting the storage floor for second-hand dynamos and motors, he is destined to receive a surprise. True, there are some dismantled machines undergoing repairs, but the bulk of the apparatus is in as neat and serviceable condition as that in a nightly operated central station. Indeed, it is by necessity the policy of an established house of this kind to let no apparatus go out that is not in good condition, as its reputation is at stake. There is, therefore, no more danger to the customer in buying second-hand than if the apparatus were just from the factory. Every machine that comes in is taken apart and overhauled, no matter how well it appears. The shops are provided with power for testing and all machines are given an actual running test before being put on the stock floor for sale. One feature that favorably impresses the visitor who is acquainted with the requirements of success with electrical apparatus is the neatness and cleanliness that everywhere prevails, and one cannot but feel that where this care prevails the apparatus must receive proper care. Besides repairing its own machinery the company does general repairing for outside concerns and has a well equipped shop, hiring good armature winders and employing the latest methods. Besides the hundreds of dynamos and motors there are in-



SALESROOM FOR SMALLER MACHINES, CHAS E. GREGORY & CO.'S ESTABLISHMENT, CHICAGO.



GALLERY AND SUPPLY DEPT., CHAS. E. GREGORY CO.

STAFF AND EMPLOYEES OF THE CHAS. E. GREGORY CO.

stock nearly a thousand arc lamps, two hundred transformers and a large number of recording meters, ammeters, voltmeters, switches and miscellaneous supplies.

The time may have been when second-hand electrical apparatus was worth only its price as junk, but that time is past. True, the Gregory Company could, if it desired, purchase plenty of apparatus that is fit for nothing but the scrap heap, but as a matter of fact it cannot afford to in view of the demand for machinery practically as good as new, such as it now sells.

The new quarters which they have occupied since Dec. 1 are excellently fitted up for the business. On the street front are a suite of offices, passing through which the visitor steps into the main shop and storage room floor, which is built on solid mother earth with cedar block paving, thus adapting it to the heaviest machinery. On this floor all heavy machinery is stored and the running tests on dynamos and motors are made. The second floor consists of a gallery which runs around half of the building. On this gallery are the armature winding and arc lamp testing departments and storage shelves for instruments, automatic rheostats, and lighter supplies. A long traveling crane running down the central open space facilitates the movement of machinery.

A CORNER OF THE REPAIR DEPARTMENT, CHAS. E. GREGORY CO.

The reasons why a second-hand concern of good reputation for fair dealing and care in the quality of apparatus sent out should prosper in the electrical field is evident. Plants are constantly being enlarged and apparatus changed to better suit the local conditions. This thrown out apparatus is usually in good shape and well fitted for service in some other plant, but it is not easy for the user of apparatus to find a customer for it, and the function of the second-hand house is to carry such goods until customers can be found.

Mr. C. E. Gregory, the founder of the concern, retired from the business several years ago. The present general manager is Mr. A. L. Kuehmstead, who has had considerable experience in practical electrical work, and is well fitted for his work by both theoretical knowledge and actual experience.

NEW YORK, N. Y.—The Non-Polarizing Dry Battery Company, of New York City, has been formed, with a capital of $200,000. The directors are: James Cruikshank, of Kingston; Charles E. Becker, of Stamford; Charles N. Brizse, Walter McDougall, John C. Kaempfer, and Jacob Biebes, of New York City.

ADVERTISERS' HINTS

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., state that while all reputable engines of the present day regulate fairly well, they do not all give good economy through their full range of power. They offer to furnish data regarding the economy of the Westinghouse engine through a wide range of load.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, say that the positions occupied by their specialties may well be termed "Seats of the Mighty."

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., advertise theatre dimmers of which they always carry a complete assortment.

THE ADAMS-BAGNALL ELECTRIC COMPANY, Cleveland, Ohio, illustrate their series enclosed arc lamp. It is highly ornamental in appearance and they are meeting with ready success in introducing this style as with others.

THE BALL ENGINE COMPANY, Erie, Pa., say that after an honorable and successful past their name is a guarantee of the excellence of their engines.

WM. T. PRINGLE & CO., 1026 Filbert street, Philadelphia, Pa., warn users against imitations of the Chapman patent attachment plug which they alone manufacture.

THE JANDUS ELECTRIC COMPANY, Cuyahoga building, Cleveland, O., claim that a half inch of carbon will burn 150 hours in a Jaudus arc lamp. They now offer new designs covering every branch of arc lighting.

THE WESTERN ELECTRIC COMPANY, Chicago and New York, remind the public that they are headquarters for wires, cables, conduits, conduit tools, fittings, electrical apparatus and supplies.

I. P. FRINK, 551 Pearl street, New York, illustrates two of his many styles of reflectors adapted to any and all classes of work.

DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., are now ready for the 1898 season with fans of new and standard makes of the ceiling desk and bracket types.

THE ELECTRIC EXHIBITION COMPANY, state that more space has already been sold than the total sold at the 1896 exhibition. It will be a great show.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, Pa., publish a little chapter of definitions. One of the words defined is "Westinghouse," which means a guarantee.

THE KEYSTONE ELECTRIC COMPANY, Erie, Pa., build street railway generators of the belted type up to 400 horse-power capacity and of the direct connected type up to 275 horse-power.

The B. and O. and Greater New York.

The Baltimore & Ohio Railroad now runs its freight trains over its own tracks into New York City. Years ago a line was built from Cranford Junction on the Jersey Central Railroad to St. George's, Staten Island, crossing the Kill von Kull on a long bridge and trestle work, and all B. & O. freight, either inbound or outbound, was handled from that point. The recent extension of the limits of New York City has made Staten Island a part of Greater New York, and the B. & O. now enjoys the distinction of being the only line from the West, except one, which has its own rails into the city of New York.

NEW YORK NOTES.

TROLLEY CARS are now running across the Brooklyn Bridge.

MR. JOSEPH KEEFE, formerly manager of the electrical department, T. N. Motley & Co., has recently associated himself with Messrs. Schiff, Jordan & Co., 232 Greenwich street, New York, and is now pushing the sale of their electric light carbons, etc.

MR. L. F. REQUA, of the Safety Insulated Wire and Cable Company, 28th street, New York, informs us that the business and orders at the present moment have grown to such proportions as to necessitate the running of their factory day and night. For this reason they have had to organize a day and night shift of workmen, busy trying to keep up in a measure with the large orders pouring in from all directions.

NEW ENGLAND NOTES

BERNSTEIN ELECTRIC COMPANY, of Boston, has made an assignment.

D. & W. FUSE COMPANY have closed their books for the year and report results as being exceedingly satisfactory. Prospects and inquiries point to a largely increased trade for 1898. Orders for their fuses are being placed from all parts of the country, and are the result of test and experience giving the D. & W. fuse the highest reputation.

NEW BRITAIN, CONN.—At the meeting of the Central Railway & Electric Co., Mr. A. M. Young was elected president. Mr. E. H. Mather was elected secretary and general manager, and Mr. F. G. Platt, treasurer. Mr. Mather has already assumed his new duties in charge of the road.

PHILADELPHIA NOTES

THE CUTTER COMPANY have just issued a new catalogue and price list of their well-known I-T-E circuit breakers, embodying all the latest types of single pole, double pole, double coil, and triple pole instruments. This will be sent upon receipt of request, either from their office, 120 Liberty street, New York, or 1112 Sansom street, Philadelphia.

SOME PITTSBURG IMPROVEMENTS.—The improvements that the Baltimore and Ohio Railroad have had under way at Pittsburg for the past 15 months have been completed with the exception of a small amount of paving between the tracks which will be done in the spring. The line now has splendid terminals at that point and sufficient trackage to handle the vast amount of business with not only economy but with celerity. The changes cost in the neighborhood of $450,000 and consist of a new yard at Glenwood, (one of Pittsburg's suburbs), a double track trestle nearly two miles in length, the changing of the line of road leading into the passenger station and the building of new freight yards near that point.

WESTERN NOTES

AMERICAN BATTERY COMPANY, whose factory at 42 West Quincy street, Chicago, was recently destroyed by fire, have established offices and new works at 174 South Clinton street, that city.

AN ELECTRICAL DEPARTMENT is recommended for Chicago by the insurance interests and is opposed by the Brotherhood of Electrical Mechanics.

TELEPHONY AND TELEGRAPHY

The Detroit Telephone Company.

BY S. P. GRACE.

IN the face of the severe business depression that has affected almost every industry in the country for the past several years, it is encouraging to look at the wonderful development and progress of the independent telephone companies. In every corner of the States new exchanges have sprung up to rival the old company. Miles upon miles of toll lines have been built, connecting together these scattered exchanges. Toll station after toll station has been established, until now almost every cross-road boasts of its telephone.

The advantages of cheap and efficient telephone service have long been recognized by the people, and, although denied them in this country, have been fully realized in the old world, especially in Switzerland and Sweden, where as a result of the low rates everybody uses the telephone.

In the United States the largest and most powerful independent telephone company is the Detroit Telephone Company, operating in Detroit, Mich. The city of Detroit has a population of about 325,000, and being a live and hustling city, well scattered, offers special inducements for a telephone exchange.

At the outset the Detroit Telephone Company decided to furnish efficient service at moderate rates, $40 for business purposes, and $25 for residences, per year. By this means they hoped to extend the field of telephonic service, and as results showed, these expectations were well founded.

ORGANIZATION.

The Detroit Telephone Company was incorporated February 20, 1896, and has the following officers: William L. Holmes, president; Charles Flowers, vice-president; Edward H. Parker, secretary and treasurer; Thomas F. Ahern, general superintendent.

It is rare that a company is so fortunate as to secure such able and competent men to direct its affairs. President William L. Holmes is widely known as a man of clever financiering and great judgment in business affairs. Mr. Charles Flowers has long been associated with legal and business affairs, not only in Detroit, but throughout the country. Besides his connection with the Detroit Telephone Company, Mr. Flowers also holds the position of Corporation Counsel

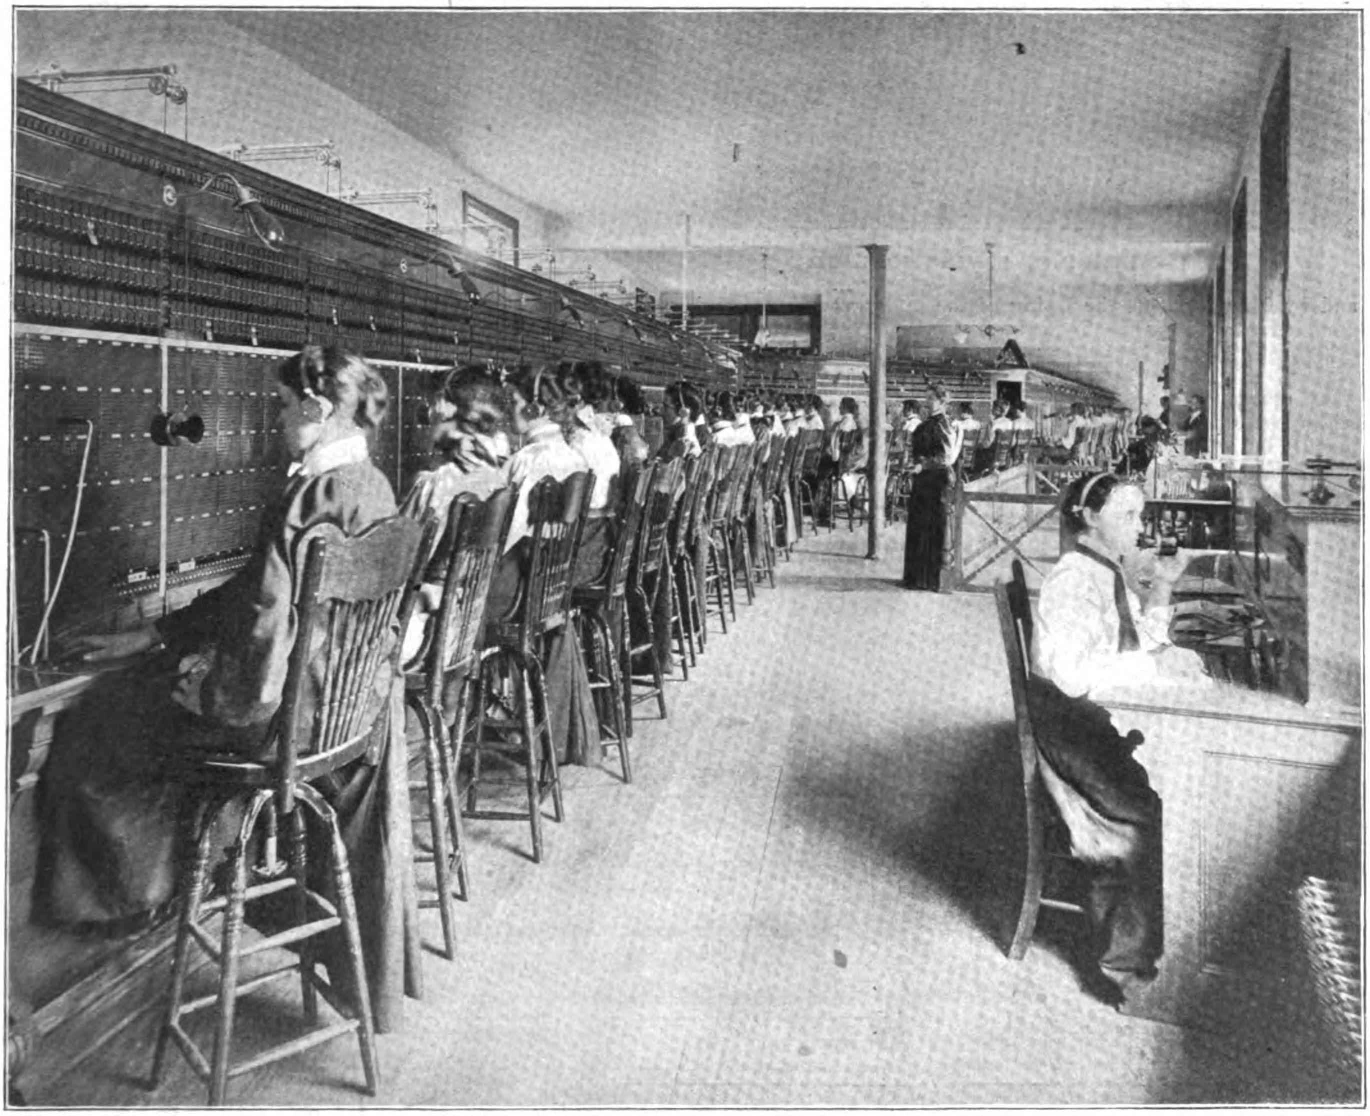

FIG. 8.—MAIN SWITCHBOARD, DETROIT TELEPHONE CO.'S EXCHANGE.
(Capacity when completed, 10,000 drops.)

of the City of Detroit. Mr. Edward H. Parker is a well known business man of Detroit and vicinity.

In choosing Mr. Ahern for the position of general superintendent, the company could not have made a wiser choice. Coupled with his seventeen years' experience with the Bell Telephone Company, is the possession of a most remarkable executive and inventive ability. Under Mr. Ahern's supervision the plans for the entire plant were rapidly developed,

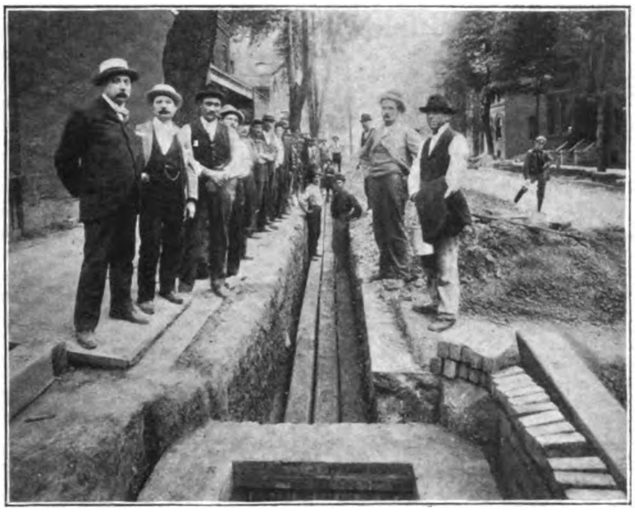

FIG. 1.—METHOD OF LAYING CONDUIT.

and by May 10, 1896, the laying of the underground conduit commenced.

UNDERGROUND CONDUIT WORK.

An ordinance of the city of Detroit provides that all wires within the half mile circle shall be placed underground, consequently in this district, and along some of the principal avenues, it was necessary to resort to underground construction. For the underground system it was decided to use multiple duct conduit. In the manufacture of the conduit the best of material is used, the result being a hard, evenly burned, salt glazed terra-cotta. The conduit is made in sizes from two to six 3-inch ducts. It comes in lengths of six feet, and, when properly laid in cement, produces a most substantial structure.

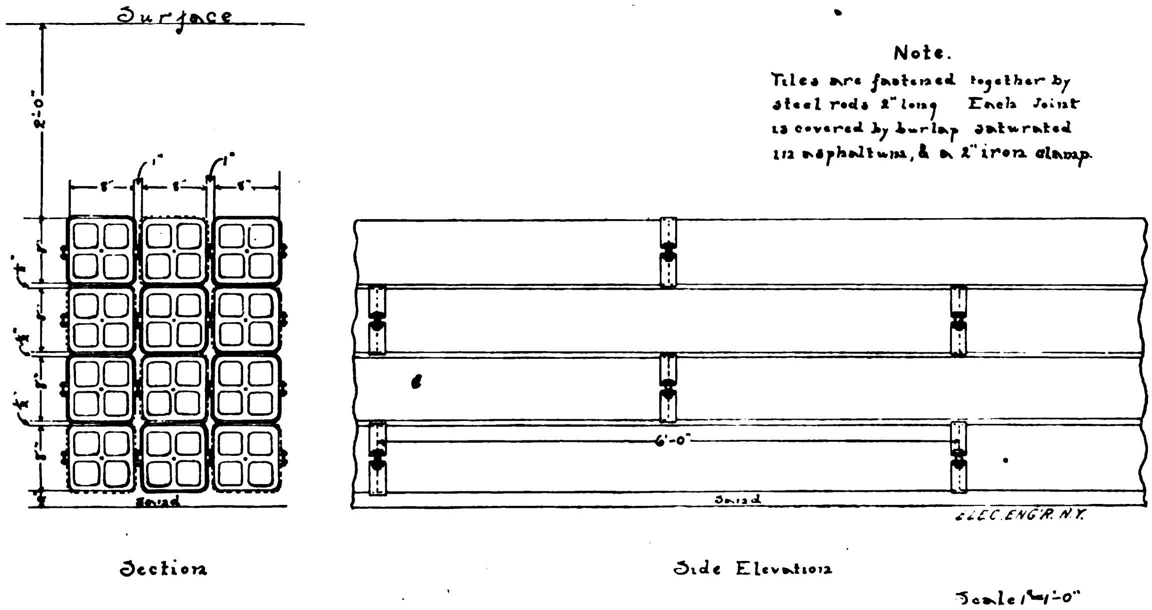

FIG. 2.—SECTIONAL VIEW OF CONDUIT SHOWING FASTENING DEVICES.

In laying this conduit the street was first excavated to a depth of three to five feet, and upon the bottom of the trench was laid a solid bed of concrete, four inches thick. After being put in place, each joint of the conduit was wrapped with a piece of heavy burlap, and afterwards sealed with cement. This made the conduit continuous and impervious to moisture. When more than one tier of conduit was laid, the joints were made to break with each other. The engraving, Fig. 1, shows the method of laying the conduit, and in Fig. 2 is shown a sectional view of the conduit.

One noticeable feature in the laying of the conduit was the fact that ample provision was made for future extension. This has always been a weak point with companies laying underground conduit, as either on account of the extra expense involved, or perhaps from lack of foresight, sufficient provision for future extension is rarely made, a consequence of which has been the continual tearing up of the streets of some of our large cities.

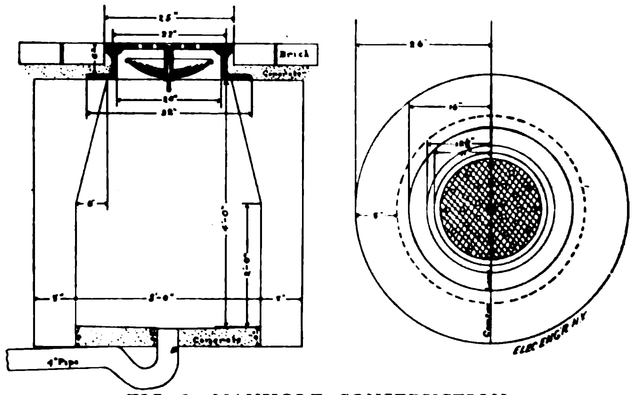

FIG. 3.—MANHOLE CONSTRUCTION.

MANHOLE CONSTRUCTION.

At all intersections and corners ample sized manholes are provided. The manholes, one of which is shown in Fig. 3, vary all the way in size from the large special, near the central office to the small type known as class D, used only for single 10-pair cables. It will be seen that the manholes are substantially constructed, of good quality, hard burned brick, laid in the best Portland cement. In the smaller sizes the sides are corbeled to receive the top casting; while in the larger sizes it rests on T-irons. Each manhole is provided at the bottom with a four-inch outlet to the sewer.

CABLE WORK.

From the terminal room, which is shown in Fig. 4, 100 pairs of cables extend through the subway into the ducts to the special manhole one-half block from central. From this point the

cables radiate in all directions to their respective points of distribution.

These cables were manufactured by the Standard Underground Cable Company, of Pittsburg, Pa., and embody the latest principles in cable design. They are made up of No. 19

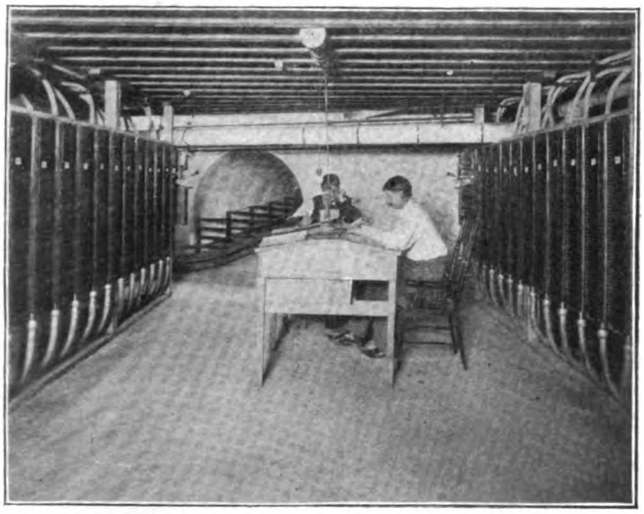

FIG. 4.—TERMINAL ROOM SHOWING SUBWAY.

paper insulated copper wires, so spiraled as to entirely prevent induction. Over all is drawn a continuous lead sheath, averaging one-eighth of an inch in thickness. One hundred and thirty miles of this cable have already been drawn in. A static capacity of not greater than .085 microfarads per mile (one wire against all others) was guaranteed and fulfilled by the

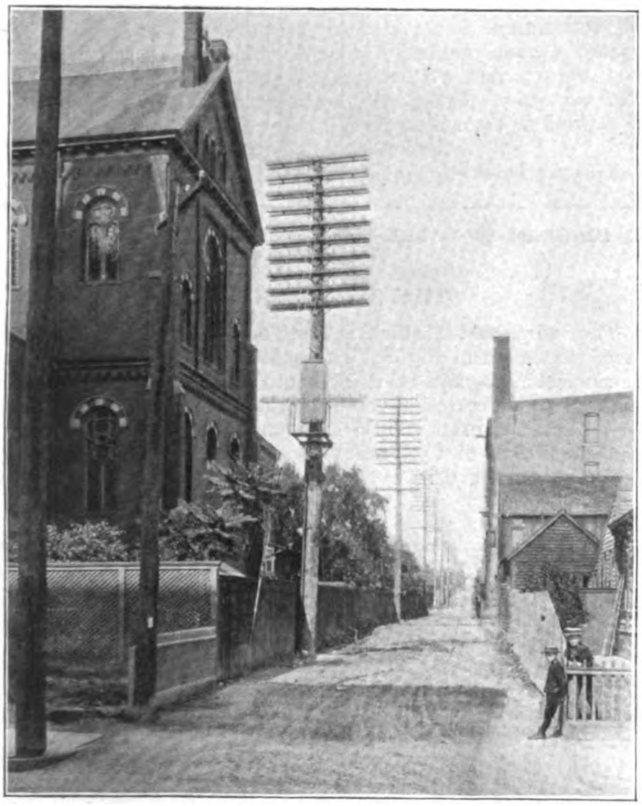

FIG. 5.—CABLE POLE WITH TERMINAL BOX.

company. All the cables are protected from electrolysis of the lead sheaths by a special system of return feeds, designed by the writer.

DISTRIBUTION OF CONDUCTORS.

The distribution in the down-town business blocks is effected by branching from the main cable a small one of 15 or 25 pairs, as required. This cable is then carried through sewer pipe to what is called an alley distribution pole, where it is run up the side of the pole in iron pipe to a terminal head, inside a specially designed weather-proof box. From the terminal head the wires are led to the insulators, and from there dropped to the different subscribers' buildings. All inside wiring is carefully done with braided duplex Okonite.

Great credit is reflected on the company's underground construction department by the fact that in all the labor of drawing in and splicing not a single wire in the one hundred miles of cable has been lost. Mr. William Collins has superintended the underground construction.

Outside the down-town district, the distribution is effected on substantially built pole lines, in the construction of which there have been used 4,500 poles, covering a distance of about 120 miles.

The main leads are designed to accommodate one hundred subscribers. At the cable pole, shown in Figs. 5 and 6, the cable from central is brought up the pole through iron pipe and distributed in a terminal box; from here tree wires run to the insu-

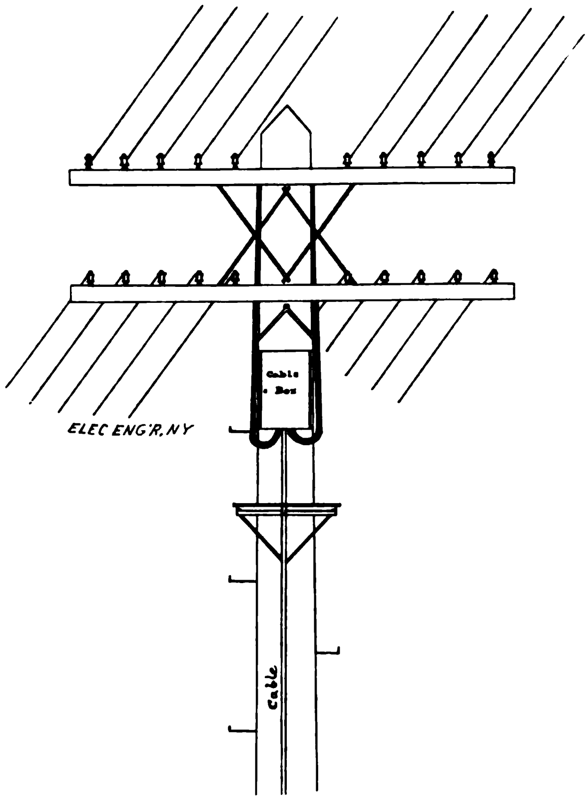

FIG. 6.—CABLE POLE SHOWING METHOD OF DISTRIBUTION.

lators, and then along the pole line to the different subscribers. Wherever centers of distribution are far removed, overhead lead cables have been carried along the pole line to these distributing points.

The outside construction has been carried out along the lines of the most modern practice. All poles are of neatly shaved Michigan live cedar, averaging fifty feet in height for the main leads, and thirty-five feet for the spur lines. The poles for the main leads, which carry from eight to ten, ten pin crossarms, are double armed, and head and side guyed with one-half inch steel strands, to anchor rods or stubs, at all corners and sharp turns. Long leads are also line guyed every one-quarter mile. Mr. W. C. Ross has superintended the outside construction, some of his careful work being shown in the engraving, Fig. 7.

THE CENTRAL EXCHANGE.

The central exchange is located at the corner of Griswold and Clifford streets in the Jones Block, a building admirably suited for a telephone exchange, because of its long flat-iron shape, which allows the switchboard to be placed in nearly a straight line. Placed upon the top floor is this mammoth switchboard, designed to accommodate 6,000 subscribers with space for 4,000 more or a total of 10,000.

Entering the switchboard room one is at once struck with

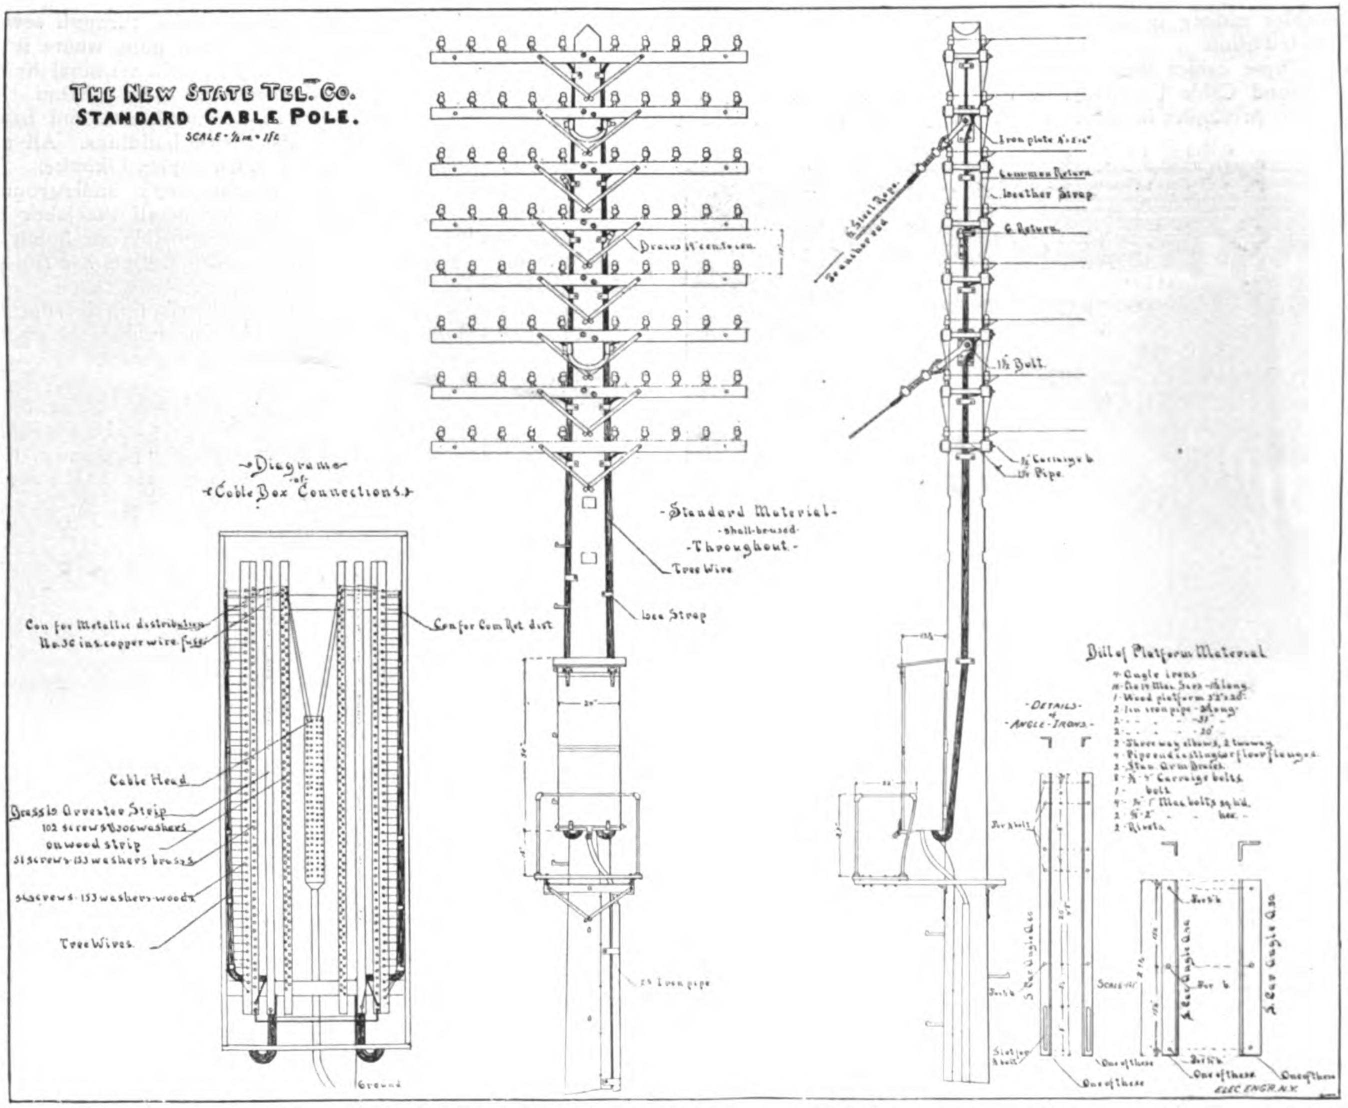

FIG. 7.—DETAILS OF POLE CONSTRUCTION AND DIAGRAM OF CABLE BOX CONNECTION.

the magnitude of the exchange, for almost as far as the eye can see, extends a line of busy girls, whose fingers make and break connections with wonderful rapidity. Noise and confusion would be expected amidst all this transaction of business, yet almost absolute quiet prevails, for the exchange work has been rapidly systematized, and the operators are thoroughly trained. It was not until Mr. Ahern attacked the problem, that quick service with a transfer system was solved. Tests on this system show an average speed of 12 seconds per connection.

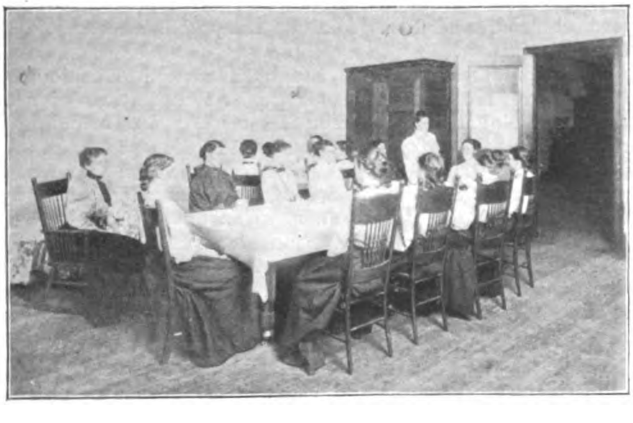

FIG. 9.—OPERATORS' DINING ROOM AT LUNCH HOUR.

THE SWITCHBOARD.

The switchboard, which is built on the "Ahern duplex system," is shown in Fig. 8. The board is 180 feet long over all, seven feet high, and is divided into 80 positions of 26 inches each. Double cotton covered wire is used for the cables, there being sixty transfer cables, each containing 200 wires, representing a total of 1,500 miles of single wire.

The switchboard as explained above is of the transfer type, connections being so arranged that any operator without leaving her position can connect with any subscriber of the six thousand. However, only a limited number of subscribers can

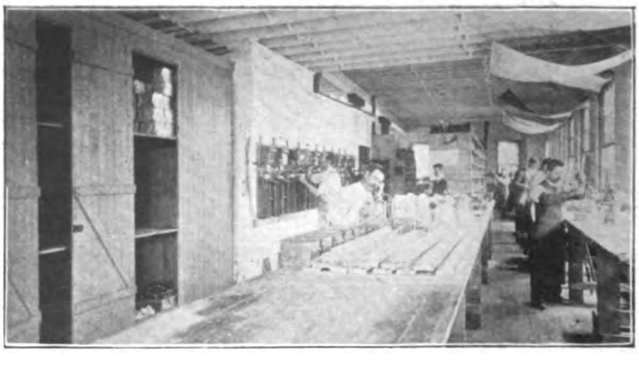

FIG. 13.—ASSEMBLING AND TESTING DEPARTMENT.

connect with a given operator, this number, as the board is at present worked, being 75.

The transfer jacks are repeated through the board at every other position, and therefore to connect with any subscriber of the six thousand, it is never necessary for the operator to reach over two feet at either side of her. The 6,000 transfer

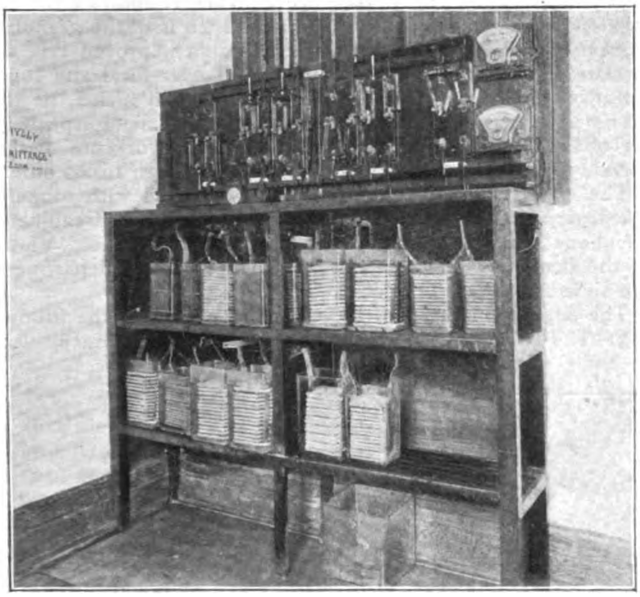

FIG. 10.—STORAGE CELLS IN POWER ROOM.

jacks are contained in a space 22 inches high by 52 inches long. All along the front of the board, and just above the keyboard, is placed a double row of 6,000 holes, behind which are the spring jacks in which the subscribers' lines terminate. Connected with the spring jacks are the annunciator drops, whose shutters fall and disclose a number when a subscriber rings in. These shutters are restored by a lever under control of the operator. Arranged in rows parallel with the front of the board, is a double row of plugs connected to flexible cords for connecting subscribers' lines together.

Fifteen pairs of plugs and cords are provided for each posi-

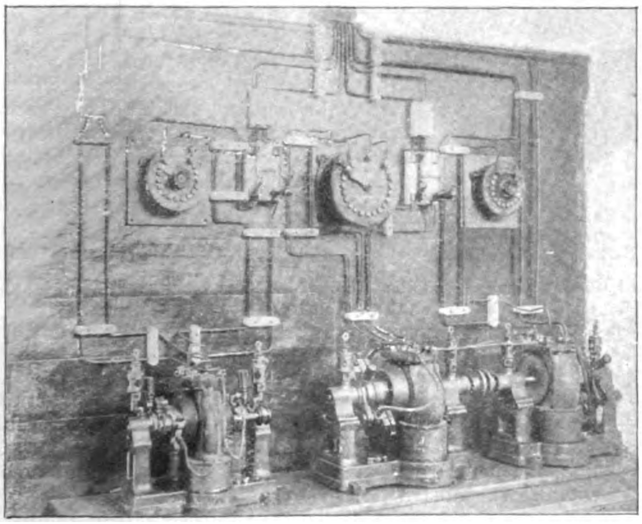

FIG. 11.—MOTOR GENERATORS IN POWER ROOM.
(Crocker-Wheeler Motor Generators for Charging Storage Batteries.)

tion. Directly in front of each pair of plugs and cords, are two buttons, one connected to the head telephone for listening, the other connected with the generator for ringing. Each operator is provided with a flexibly suspended transmitter and a receiver held against her ear by means of a head band. Metallic circuits are used throughout the board.

For the operation of the switchboard, day and night service, there are required at present 112 girls, which number will be increased to 170 when the board is completed. Every effort is made for the comfort and healthfulness of the operators, as it is fully realized that efficient service cannot be obtained from

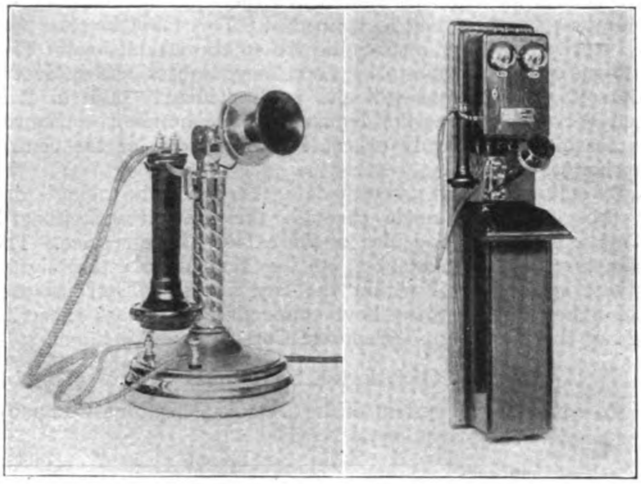

FIG. 12.—DESK AND WALL TYPES OF INSTRUMENT.

overworked operators in unventilated rooms. Back of the switchboard room is located the lunch room, a large and well ventilated room in charge of a matron. Here tea, coffee and cakes are furnished gratis to the girls at lunch hours. A

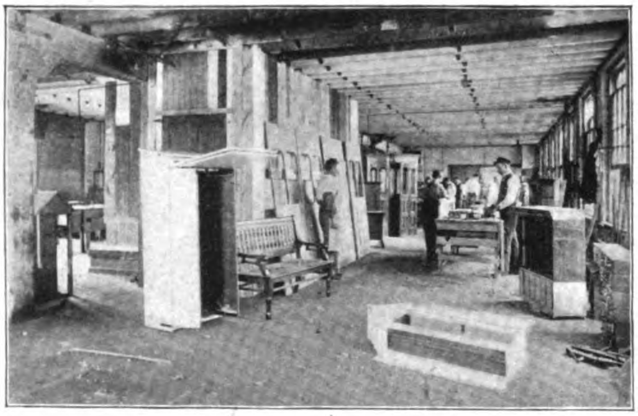

FIG. 14.—THE CABINET MAKING DEPARTMENT.

group of the girls just sitting down to luncheon is shown in Fig. 9.

Current is supplied to the transmitters and other circuits by

FIG. 15.—OFFICES OF THE ENGINEERING DEPARTMENT.

storage batteries, charged from the Edison mains by means of a motor generator. The engravings, Figs. 10 and 11, illustrate the power room, showing batteries, motor generators and

alternating ringing generator. Mr. C. L. Zahm is manager of the operating room.

At the present time there are 4,767 subscribers working on the central switchboard, and it is expected that inside of six months 1,500 more will be connected. This rapid increase was a surprise to the company, and led to the establishment of a sub-station to accommodate 1,000 more subscribers in North Detroit. Sub-stations will also be immediately built in East and West Detroit, as the demand for telephones is constantly increasing, and already overtaxes the capacity of the central exchange.

By actual count at a recent date, there were in a single day 53,859 connections made through the Detroit switchboard. This will give a good idea of the extent of the service. The company had on January 1, no less than 6,230 actual signed 3-year contracts, all within the city limits of Detroit. Besides these the company have connection with 2,258 subscribers of the New State Telephone Company of Michigan.

TOLL LINE SERVICE.

To complete the system of the Detroit Telephone Company, and furnish toll line service, the New State Telephone Company was organized. During the past summer many miles of copper metallic toll lines have been built. These radiate in all directions, and make connections with nearly 100 exchanges and toll stations owned by the New State Telephone Company. This provision of toll service is a vital point, and it is one in which a great many independent companies have been weak.

MANUFACTURING FACILITIES AND INSTRUMENTS.

The Detroit Telephone Company is also unique in the fact that it is intimately connected with a manufacturing company. This company, called the Detroit Switchboard and Telephone Construction Company, manufactures all the instruments, switchboards, drops, jacks, coils, etc., required by the Detroit Telephone Company and the New State Telephone Company. Up to the present time it has taken the entire output to supply the two local companies, but it is the intention of the company to enter the market this year and compete for outside business.

A word might be said about the instruments manufactured by this company for the Detroit Telephone Company and the New State Telephone Company. The wall set, Fig. 12, is of neatly finished quartered oak, with nickel trimmings on all exposed metal parts. The transmitter, which is of the granular carbon type, is worked with two cells of an improved type of Leclanché battery, and talks equally well over local and long distance lines. The desk set, Fig. 12, is a full nickel, neatly designed instrument, and has met with great demand especially for offices. Both these instruments for local work are of the series type, with generator wound to ring through 10,000 ohms.

The cabinet department is also well equipped with modern machinery and turns out all the booths, switchboard cabinets, telephone boxes, etc., required by the local companies. Views of the instrument department, and of the cabinet department are shown in Figs. 13 and 14.

The engineering staff of the company comprises the following: T. F. Ahern, general superintendent; S. P. Grace, electrical engineer; W. C. Ross, superintendent of construction; William Collins, superintendent of underground and cable construction; E. E. Given, superintendent of equipment; F. G. Roberts, mechanical engineer; Chas. L. Zahm, superintendent of switchboard construction.

A glimpse of the offices of the engineering department is shown in Fig. 15, and the portraits of the staff are shown in Fig. 16.

In conclusion it is well to call attention to the remarkably short space of time in which this exchange was built. Eighteen months ago not a single piece of conduit was laid, not a single wire strung. To-day there exist 30 miles of underground conduit, 120 miles of pole lines, two large switchboards, and a factory well equipped for telephone construction.

Equally vigorous has been the progress of the State Company. Fifteen hundred miles of toll lines, 35 exchanges, and 75 toll stations are the work of a single summer. Certainly this is rare progress.

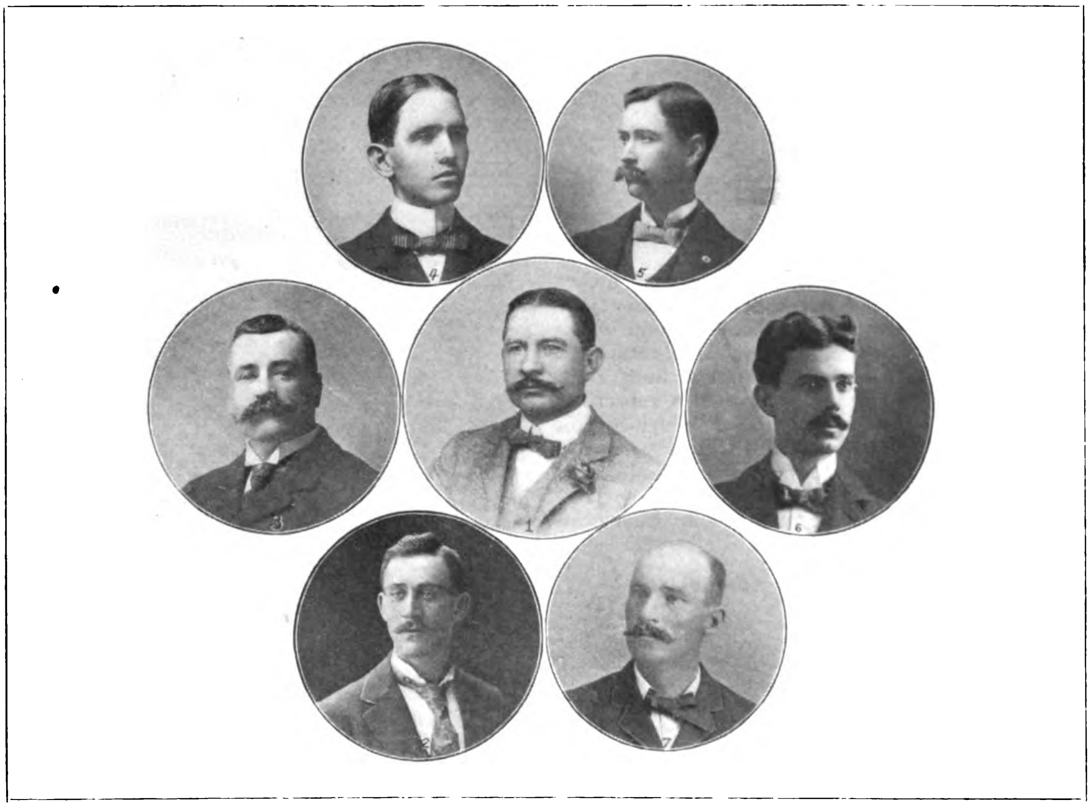

FIG. 16.—THE ENGINEERING STAFF.

1. T. F. Ahern, Gen'l Superintendent. 2. Chas. L. Zahm, Supt. of Switchboard Construction. 3. William Collins, Supt. of Underground and Cable Construction. 4. S. P. Grace, Electrical Engineer. 5. E. E. Given, Supt. of Equipment. 6. T. G. Roberts, Mechanical Engineer. 7. W. C. Ross, Superintendent of Construction.

Tests of the Synchronograph On the Telegraph Lines of the British Government.[1]

BY A. C. CREHORE AND G. O. SQUIER.

IN April, 1897, a paper[2] was read before the American Institute of Electrical Engineers, describing the general principles of the synchronograph and the experiments at that time completed in developing it. As stated therein, the next step desirable was to test the system upon long telegraph lines having considerable distributed capacity, the length of the only line used up to that time being thirteen miles. Since then opportunity has been presented to make these trials on actual lines of considerable lengths and having different distributed capacities. Through the courtesy of Mr. W. H. Preece, Engineer-in-Chief of the British Postal System, every facility has been afforded for conducting the experiments on the telegraph lines of the British Government.

The tests were made over loops of varying lenghts from the General Post Office, London, where both transmitters and receivers were located. The longest loop tried was 1,097 miles in length, from London to Glasgow, Aberdeen, Edinburgh, and return to London by a different pole line. This contained some iron wire and also 48 miles of underground cable, and a total value of K R equal to 261,000. In the course of the trials the surprising result was discovered that the synchronograph could operate the Wheatstone receiver approximately three times as fast as the Wheastone transmitter on any line, provided the mechanical limit of the receiver is not already reached.

One of the most important results of the trials to be described has been to emphasize the probability that the sine wave possesses superiority over other forms of wave for any speed, slow or fast.

The first series of tests were conducted on Sunday, August 8, 1897, over a line from London via Leeds to Newcastle-on-Tyne, and return to London via York. Over this line, with no earth, messages were received with ease at a frequency of 652 to 1,304 alternations per second.

Tests were then made over a longer line with greater K R, the route being from London via Leeds to Glasgow, and return via Edinburgh, Newcastle-on-Tyne, and York to London. As before, through this line without earth, K R being 31,771, a current was sent having a frequency as high as safety to the alternator permitted, viz., 652 complete waves per second, and no limit of speed due to the line was reached, the messages being received with perfect clearness.

The authors give curves showing the speed obtained by the Wheatstone system and show that it may be represented closely by an equation of the form K R W = a constant.

On Sunday, August 22, 1897, experiments were made over each line for speed as follows: (1) Wheatstone transmitter and receiver; (2) synchronograph and Wheatstone receiver; (3) synchronograph and chemical receiver. The results of these tests are given and the authors draw the following conclusions from the entire series of tests.

The results of the experiments described show that the use of an alternating electromotive force, which does not rise suddenly and fall off as abruptly as is the case with that of most transmitters, but which rises gradually from zero to a maximum and falls again to zero as gradually, is the best kind of wave for use on actual lines with distributed capacities.

The synchronograph, which employs this kind of an alternating electromotive force made and broken always at the neutral points, has thus far proved to be better than other transmitters for the transmission of electrical waves over a given line at any speed, slow as well as fast. An examination of the various methods employed for increasing the speed of working on submarine cables shows not only that in such methods the waves are made of equal lengths, but that an endeavor is made to compensate for the square tops of the electromotive force waves of the transmitter, which is usually accomplished by the aid of condensers or auxiliary electromotive forces judiciously arranged in shunt circuits. In other words, the attempt is made by these devices to approximate a sine wave as nearly as possible, while the remedies which can be applied by such means at best only approximate this form of wave. The synchronograph adopts a smooth wave, approaching practically the sine wave in form as its fundamental principle, and supplies a simple method of using the waves generated by an alternating dynamo.

The substitution of the synchronograph for the Wheatstone transmitter on the identical lines, using the same receiver in each instance, showed a speed of operation by the synchronograph about three-fold faster, provided the mechanical limit of the receiver was not already reached. The causes of this great increase of speed are differences in the waves which pass through the receiver; since the only way by which the identical receiver can distinguish between transmitters is by differences in the actual waves received. The waves of current passing through the receiver, which control its operation, are not of the same shape as the electromotive force waves of the transmitter. The current waves with the Wheatstone transmitter, for instance, have more or less rounded tops, but they maintain the same frequency as the transmitter, and waves for a dash are longer than for a dot. The current waves received from the synchronograph are not true sine waves in the receiver, even though the electromotive force is truly harmonic, but the frequency is the same as that of the generator and the waves are of equal lengths. The current wave from an alternator, may approximate a sine wave very closely if the electromotive force is harmonic, and in fact if there is no leakage on the line it will be truly harmonic; or under some circumstances it may still be harmonic, provided there is a correct relation between the leakage, resistance, inductance, and capacity. There are thus at least two causes which account for the slower speed with the Wheatstone transmitter, the fact that different frequencies or wave lengths are used in the transmitter and the departure from the sine form of wave.

Another cause for gain in speed by the synchronograph is the fact that higher voltage was permitted with it than with the Wheatstone transmitter, although it is difficult to estimate the precise amount of gain due to this. The reason for permitting different voltages lies in the construction of the instruments themselves; for with the synchronograph the contacts are made and broken at the zero points of the waves, and thus even when considerable capacity is present on the line, the amount of sparking is almost nil under circumstances when the Wheatstone transmitter would produce a powerful spark owing to the sudden application of the full voltage.

In view of these trials with the Wheatstone instruments it will be of interest to extend the experiments to other forms of instruments such as are now used or proposed for cable or automatic working. The gain in speed expected is less than with the Wheatstone system, since in long cables the transmitters used already employ waves of equal lengths.

It was interesting to observe whether a high frequency current, such as was used in these experiments, passing in a continuous loop of a thousand miles through a thickly-settled country, would cause any material disturbance in the telephone circuits of the region, but no such disturbances were reported, although orders were given for this to be noted.

It is believed that the Government control and operation of the telegraph would prove a great benefit to the people of the United States. The natural relation between this service and the general postal service requires that they should be under the same department for the most efficient and economical management.

[1]Abstract of a report to the Postmaster-General of the United States. Read before the Franklin Institute, January 19, 1898.

[2]The Synchronograph; a New Method of Rapidly Transmitting Intelligence by the Alternating Current. Electrical Engineer, Vol. XXIII., May 5, 12, 19, 1897.

A New West Indian Cable.

A submarine cable has been laid and is now open for business between Bermuda and Turks Island (in the West Indies). The cable is owned and will be operated by the Direct West India Cable Company, working in connection with the Commercial Cable and Postal Telegraph Companies. The rate from New York City to Turks Island will be fifty-six cents per word.

An Hawaiian Cable Offer.

James A. Scrymser, president of the Pacific Cable Company, appeared at Washington on January 18 before the House committee on interstate and foreign commerce to advocate a contract with the United States which, he said, he would not call a subsidy, whereby the company would transmit all official messages for $175,000 a year, for twenty years, from San Francisco to Hawaii, China, and Japan, with a proposition to extend it to Australia for $75,000 additional per year. He said that during the Venezuela trouble it had cost the Government $5,000 for one diplomatic message, and no one knew what the Govern-

ment's aggregate expense was in this connection. He said that it would take 8,000 miles of cable from San Francisco to Honolulu, and was sharply questioned by the committee as to the alleged monopolistic features of his proposition. He declared that his company was responsible, and had the experience to do what they proposed.

Public Control, Ownership or Operation of Municipal Franchises ?—V.

With Special References to Electric Lighting.*

By R. R. BOWKER.

(Vice-President and General Manager New York Edison Co.)

OTHER AMERICAN CITIES.[1]

PHILADELPHIA has a municipal water supply, started in the last century, which has long been its pride and has been considered very profitable to the city. But the figures apparently do not cover interest or depreciation on cost, which is indeterminate, one estimate being of $28,000,000. It started municipal gas works in 1841; these have steadily degenerated until they became a notorious disgrace to the city, and in November, 1897, an ordinance was passed leasing the plant to the United Gas Improvement Company for 30 years. The municipal plant supplied about 60 per cent. of the gas used, purchasing the rest from a private company at 37 cents per 1,000 cubic feet in gas holder. Last year there was manufactured about 5,000,000 thousand cubic feet, 3,000,000 of coal gas and 2,000,000 of water gas; the public lighting consumed 674,000 of this, 545,000 being for street lamps and there was "unaccounted for," 1,132,000. There were 168,644 consumers on the books of the bureau. The annual report complained bitterly of the bad condition of the system, and of the difficulty of obtaining adequate appropriations for modernizing it. The price of gas has been $1 per 1,000 cubic feet, said to be of 19 candle power, but the gas has been notoriously poor. The receipts in 1896 were $3,318,337, and a gross profit of $352,988 was reported. It is stated that $674,031 worth of gas is supplied free to the city. An accountant's report, however, shows $281,569 additional expenses, aside from interest on investment, improvement cost, etc., and he figures, including extension improvements, a net deficit for the past three years of $416,000 per year.†

Philadelphia's electric lighting companies are now for the most part consolidated in the hands of the Pennsylvania Heat, Light and Power Company, which includes the Edison system. There are in the city and suburbs 6,661 street arc lights at 30 to 37 cents per night, or $109.50 to $135.05 per year, costing the city about $800,000 yearly. The price of electric lighting in Philadelphia is on a base rate of ¾c. per 16 candle power lamp hour, somewhat, but slightly, reduced by discounts. In 1894 a Committee of Councils appointed to consider the establishment of a municipal electric plant reported strongly against the plant.

Chicago was formerly supplied with gas by nine companies with at least three sets of pipes in some streets, of which eight have been consolidated in 1897 into The People's Gas, Light and Coke Company, originally organized as the Gas Trust Company in 1887, but blocked by legal proceedings until the consolidation act of 1897. The consolidated company has a capital stock of $25,000,000, on which it pays 6 per cent. dividend, and a bonded indebtedness of $29,000,000 at 5 per cent. interest. It has about 158,000 customers, consuming over 5,000,000 thousand cubic feet; its revenue, including by-products, is above $6,000,000. The city receives 3½ per cent. on gross receipts or at least $150,000 per year exclusive of city and State taxes. The price of gas, which was $2.50 in 1883, was made in 1893 $1.25 with a reduction of five cents per year, by which the price is now $1.

In electric lighting, the Chicago Edison Company has consolidated into it eight other companies, including all except four small companies still existing on the south side. The Chicago Edison Company (Nov. 30, 1897), has 6,000 customers, with 5,500 arc and 234,000 incandescent lamps and 7,400 horse-power in motors. The smaller companies, south of Thirty-ninth street, show 2,500 customers, with 1,600 arc and 67,000 incandescent lights and but 45 horse-power in motors. Besides these there are probably 200 or 300 private plants, aggregating perhaps 8,500 arc and 200,000 incandescent lamps and 1,000 horse-power in motors. This shows a total in electric lighting of 15,700 arc and 500,000 incandescent lamps, the equivalent of 657,000 16 candle power lamps and 8,445 horse-power in motors, in all nearly 900,000 equivalent. Chicago reported, 1896, 1,624 street arc lamps, of which 459 were supplied by private companies at $102.70, 59 at $137.50 and 116 from a municipal plant at $96.76. Oil chiefly is used by the gas companies; soft factory coal costs $1 to $1.10 at riverside factories. Chicago has no general subway system, but the conductors are underground except in the suburbs. The subway legislation requires that for new grants the consent of property holders shall be required for new subways as for new street railways.

Boston has been supplied with gas by the Boston and the Bay State Companies in the city proper and by five local companies in its suburban districts. All the Boston interests have been consolidated (Dec. 1897) in the New England Coke & Gas Company, with $17,000,000 stock and with $17,000,000 bonds. The two chief companies have paid 10 and 9 per cent. dividend on capital of $4,500,000. The price of gas in Boston is now $1. Boston has its electric lighting chiefly from the Edison Company, with $3,750,000 capital, paying 7 per cent., and no bonds, and the Boston (high tension) Company with $1,700,000 capital, paying 6 per cent., and $1,062,000 bonds, besides which there are a suburban company of $174,400 capital, a small block plant company of $9,500 capital and 200 private plants. The Edison Company reports 1,541 arc lamps, 158,000 incandescent lamps and 6,109 horse-power in motors; the Boston Company (1896) 2,193 arc lamps, 50,629 incandescent lamps and 1,468 horse-power in motors. The city lighting is supplied by the Boston Company with 2,159 arc lamps averaging 35 cents per night or $127.75 per year. The price of incandescent lighting is 9-10c. per 16 c. p. lamp hour. base rate, with lamps, subject to discounts; the average return for 1896 was 7-10c. for incandescent lighting. All these systems are under the control of the Massachusetts Board of Gas & Electric Light Commissioners, from which permission to increase capital, extend systems and organize new companies must be obtained, to which detailed annual reports must be made, and by which a valuable annual report is issued.

Brooklyn obtains its gas supply from the Union Gas Company, a consolidation of five or more former companies. It obtains its electric lighting from the Edison Company, which has consolidated with it the Citizens (high tension) Company, and from two small companies in the Eastern district, besides private plants. A new Kings County Gas & Illuminating Company has recently been organized with a view to electric lighting. The Edison Company has a capital of $3,750,000, paying 6 per cent. dividends, and bonds of $1,000,000 paying 5 per cent. interest. The price of incandescent lighting is 1c. less discounts for average consumption, and less additional discounts for large bills, bringing the average price below ¾c. per 16 c. p. lamp hour. Brooklyn has 3,200 street arc lamps, of 1,200 nominal candle power, for the most of which it pays 34c. a night, or $124.10 per year.

Toronto, Canada, should be cited as a city which has taken over the ownership of its street railway tracks, which it rents to the Toronto Railway Company, under a carefully drawn agreement, giving the city from 8 per cent. up to 20 per cent. of gross receipts and assures reasonable fares, special tickets being sold for working men's hours at 8 for 25c., and children's tickets for school hours at 10 for 25c. Ordinary tickets are 6 for 25c., while at Kingston, with a private company, the price is 8 tickets for 25c. Two years since, the municipality proposed to establish a municipal lighting plant, but it was voted down, and the gas system is operated by the Consumers' Gas Company, and the

*This paper is written from the point of view of the economist and citizen, but with the data and experience gained as the executive of the New York Edison Company. To my mind, this should not involve opposition of interests; as he most serves his party who best serves his country, so he most serves the interest of a public-service company who best serves the public. I mention the relationship, however, to forewarn readers of any unintentional bias. It is difficult for any outside the business cited, in an academic discussion, to obtain real bases of comparison.—Reprinted by permission from Municipal Affairs, the Reform Club Quarterly.

[1]Lack of sufficient and reliable data compels the omission of detailed statements concerning Detroit.

†See the articles by Dr. Frederick W. Speirs and Col. John L. Rogers for a more detailed discussion of this subject.—Editor.

electric system by the Toronto Electric Light Company. The city makes a contract for street arc lamps each four years.

Electricity in Municipal Engineering.[1]

BY PROF. R. B. OWENS.

(Dept. of Elec. Eng., Univ. of Nebraska.)

MY object in presenting this paper is to emphasize the economy which can often be effected by generating at one point all the power required by a municipality, and its distribution for whatever purposes, by electrical means.

But I am not to be understood as advocating the community ownership and operation of any interest which can be as well administered by individuals. On the contrary, I believe the vicious efforts, so noticeable of late, to shift individual responsibility to that popular misconception, "the government," marks the begining of another serious setback to the growth of democratic institutions.

However, I will not attempt a discussion of private versus municipal ownership, even the phase presented by the lighting question. I only wish to show the economy of combining the several problems in municipal engineering involving the use of power and to point out a further considerable field for the use of electrical apparatus.

The several principal problems referred to are, of course, the supply of water for potable and other uses, the disinfection and disposal of sewage, the destruction of ash bin refuse, and street lighting.

When a city is so fortunate as to be able to get good water from a nearby river or lake, with or without pumping, much that I have to say will not apply. But in the majority of cases in our flat western country water is only obtainable from wells, driven or dug, and when a considerable amount is required, as for municipal uses, it is generally necessary to separate the wells as far as practicable, because of the limit to the supply which can be continuously obtained per unit of volume of water-bearing strata.

In small towns of a few thousand inhabitants, where the underflow is good, it is usual to find driven wells ten to twenty feet apart and a direct-acting steam pump over each, an arrangement, which, as a rule, requires the construction of a railway siding for rapid coal supply. In larger towns of from fifty to sixty thousand inhabitants and upwards, it is not unusual to find half a dozen pumping stations from one-half to one mile apart, each with a full complement of boilers, steam pumps, and attendants, and the whole operated apparently as much in the interest of the coal dealers and those on the pay roll, as for the taxpayers. A one or two cylinder pump without fly wheel, lifting from a single dug well and discharging directly into the mains, is usual.

In a case of this kind recently coming to my notice, I urged the immediate substitution for the steam pumps of an equal number of triplex power pumps operated by constant torque variable speed motors, the current for such motors to come from a central power plant equipped with economical machinery and suitably located.

The annual saving as the result of such a change was estimated to be more thatn fifty per cent. of the total cost of operation. It might be remarked here that the recent appearance of satisfactory constant torque motors, in both alternating current and direct current types for operation from constant potential circuits, removes the last difficulty in the most general application of electric power, and now it can be confidently hoped that non-expansive steam-working, as in boiler feed pumps, drain pumps, etc., in our lighting and power plants and also in many cases of pumping from wells against a constant head for city and other supply, will soon become a thing of the past.

The usual method of handling sewage is by means of a water carriage system draining into the nearest stream without disinfecting. But this practice is barbarous. No system of sewage is complete which does not abstract the solid matter and sterilize the liquid portion before turning into our waterways.

Chemical methods of sewage disinfection, when effective, are expensive, and it would seem that electrical methods must supercede them in the future. The two principal methods of manufacturing a disinfecting fluid by electricity are Hermite's and Woolf's, the former being used principally on the continent and the latter in this country. They do not differ much except in detail. In both systems the disinfectant is obtained by passing a large current of electricity at low pressure through sea or salt water, prior to, or after being mixed with the sewage. From this results the formation of certain hypochlorites, hypobromites and iodine compounds, which latter are for the most part in the form of iodates, all strong oxidizing agents, directly or indirectly.

One installation of the Woolf system reported, consists of a 15 horse-power engine with suitable dynamo, tanks, etc. A bacteriological examination made by competent persons showed almost perfect sterilization. This plant is considered sufficient for disinfecting the sewage of 30,000 population if run continuously.

At usual rates for fuel and attendance, the cost per inhabitant per annum was shown to be about twenty-five cents. A similar cost per inhabitant has been obtained elsewhere. It will be seen, however, that this figure can be reduced to a small fraction of itself if the system were operated as a part of a combined plant instead of as a small separate one. As compared with other systems of sewage purification, chemical, land filtration, or a combination of chemical and land systems, the cost per inhabitant per year by the electrical system, even when current is supplied from a special plant, is apparently less by from one-half to two-thirds.

Another important point to note in this connection is that the electrical system while cheaper and in general more effective, requires power at practically a uniform rate, a condition fitting in very perfectly with the economic operation of a pumping plant and the requirements of a plant to burn and utilize town refuse.

The matter of disposal of ash bin or more generally town refuse, has not received the attention it deserves. There is but one successful method of handling it, and that is, to burn it; but town refuse has a calorific value equal to about one-fifth that of ordinary coal and consequently may become with proper arrangements for its burning a source of profit instead of an expense.

A difficulty in utilizing the heat energy of town refuse for street lighting is that it requires to be burned at a very regular rate the twenty-four hours. To meet this, the so-called thermal system of energy storage has been devised, but since the power required for pumping, supposing some reservoir capacity in the water system, and for the electrical purification of sewage, is in many cases practically constant and more than that obtainable from the refuse, a combination plant would save the expense of such a thermal system and accomplish as much.

It is seen then that a destructor plant will combine very perfectly with a plant to supply current for sewage disinfection and for pumping.

For street lighting electricity need only be considered, as the demand for electric illumination, as against other means, is almost universal. But the peculiarity of municipal lighting as compared with ordinary commercial lighting is the constant power required while lights are in use, a feature which again lends itself happily to combination with a pumping plant and plant for sewage disinfection. Also in many cases it will be found that the amount of power required for lighting is not far different from the amount required for pumping. Now from what has been said, it will be evident that in many cases a combined plant can be designed to burn and utilize the ash bin refuse, do the pumping of water from a series of scattered wells, and supply current for street lighting and sewage disinfection, in which all the machinery will be loaded very nearly to full capacity, twenty-four hours a day.

The extremely uneconomical machinery used for pumping in many places to-day, and the demand for better sanitation, offers, it seems to me, a very considerable further field for electrical machinery and one which I trust will not long remain uncultivated.

[1] Read before Northwestern Electrical Association. Abstract.

WILLIAM DINWIDDIE, the eminent photographer of Washington, who has been taking a series, both scenic and industrial, for the Baltimore and Ohio Railroad, has completed the outdoor work and is now engaged in making proofs of the eight hundred or more negatives that he secured during the summer and fall. About one-third of this work has been completed, and photographic experts, who have examined it, pronounce it the finest collection of its kind that has ever been taken. One of Mr. Dinwiddie's scenic B. & O. views has received honorable mention in the Salon at the Carnegie photographic exhibit in Pittsburg.

VOL. XXV. NEW YORK, FEBRUARY 3, 1898. No. 509.

Exploded Examples.

THIS is peculiarly an age of investigation when every fact and every theory has to prove itself worthy of renewed confidence and acceptance or be dismissed into the limbo of exploded, fraudulent fables. The habit of inquiry has so fastened itself upon our times as to have become almost a disease, except in France, where they still have a robust cowboy way of lynching a man and considering it an outrage on the community if he dares afterward try to establish his innocence. It seems to us that the "prove all things" method is the best. Once in a while, the world may lose a beautiful dream, but the gain in solid truth counts for something as an offset.

We have thus ourselves in a modest way been trying to get at the facts in regard to municipal lighting plants, the data about which only too often appears to be in the nature of that upon which Col. Sellers based his imaginary wealth. We get tired of hearing about the greed and grasp of private corporations when one after another they are driven to the wall of bankruptcy by low prices. We become rather sceptical about the purity of municipal plants when every instance that is probed shows either a state of corruption not previously suspected or else sees the figures of cost run up so high that one wonders how the original estimates could ever have secured the credence of any intelligent community. At this moment we are publishing the able review of the municipal plant question by Mr. R. R. Bowker, of whose public spirit so many proofs have been given to the citizens of New York. It will be followed by the counter arguments of Prof. John R. Commons, whom it is a pity to anticipate; but since he quotes ancient and fishy data when more modern instances abound, we must once more venture into the fray.

Two of the standard municipal plant examples are Batavia and Dunkirk, in this State. Chicago was once a brilliant case to cite, but with prices up around $175, is not so frequently cited. Detroit is later, but with costs somewhere between $100 and $110, is not so much in favor. But for years past little Batavia and modest Dunkirk have been quoted and are still cherished by Profs. Commons and Frank Parsons. It so happens that Mr. Horatio A. Foster, who made our inquiry in 1894, was recently called in as an expert at Tonawanda, N. Y., where the local company, under favoring conditions, was offering 170 arc lights at a round figure of $78.35 per year, or $.0195 per lamp per hour, rather than sustain the competition of a new municipal plant. Mr. Foster was, therefore, commissioned to look into these wonderful instances of Batavia, Dunkirk and Jamestown, in this State—and found just what might have been expected. He found that in Batavia, on any proper, scientific basis of bookkeeping the cost per lamp per hour was $.0204. In Dunkirk it was $.0251, and in Jamestown it was $.0217. The plant in Dunkirk is in bad shape, changes are being made on the plant and an addition of $10,000 will be necessary to the city's investment.

Nor is this all. Mr. Foster says of Jamestown: "Although the Jamestown plant is kept in most excellent condition as regards the station itself, I am told by the best authorities that lamps are often out for a long period, and in the case of two lamps they were said to have been out for upwards of four weeks. I am told that it is not infrequently the case that a whole circuit will be out for some length of time during the evening. Of course this being a city plant, there is practically little growling about the results, but it is needless to say that if the street lamps were in the hands of a private company such delinquency would be very vigorously brought to the attention of the company by notices in the local papers and growls from individuals. Personally, I am of the opinion that Jamestown would be considered better off if its plant were leased to an individual corporation and a definite sum per light paid by the city."

This reminds one of the recent remark from Detroit that one great argument for a municipal plant was its superiority in respect to "outages." Evidently that argument "cuts no ice" at Jamestown.

Mr. Foster goes on to point out that the service offered by the Tonawanda Company is below the cost of that of several municipal plants in New England, according to the careful returns of that trustworthy body, the Gas and Electric Light Commissioners of Massachusetts. The figures of cost per arc lamp per hour show up as follows:

Braintree, municipal	$.0455
Danvers, municipal	.0329
Marblehead, municipal	.0239
Middleborough, municipal	.0400
Peabody, municipal	.0220
Reading, municipal	.0553
Wakefield, municipal	.0752
Tonawanda, N. Y., private	.0195

In conclusion we may note Mr. Foster's estimate of a cost of $200 to $250 per lamp installed, for a street lighting plant at this time; an amount very different from that upon which municipalities are invited to make the plunge into a new business enterprise.

Englewood and Chicago Electric Storage Battery Road.

EVER since the consolidation of storage battery interests in this country, electrical engineers have looked forward with a feeling of satisfaction and vindication to the time when the storage battery would displace the uncomely overhead and expensive underground trolley. The problems, which had up to that time occupied the minds of a few investigators, were now being attacked by numerous inventors desirous of producing a light weight accumulator, one which would not deteriorate rapidly, and a generally practical system of handling storage roads.

While these questions received the closest attention of electrical engineers, the steam generating and transmitting, as well as electrical machinery, were being marvelously developed. But while we heard of storage batteries performing many useful functions in central stations, the only roads, worthy of mention, whose cars were equipped with accumulators, were those of Berlin, Paris, Vienna and Birmingham. On the other hand, the Metropolitan Railway Company of New York, after a thorough investigation of all existing methods of street car propulsion, adopted the electric conduit system over a large network of thoroughfares.

We have watched, meantime, in conjunction with everyone interested in electric traction, ever since its inception in 1895, the progress and success of the Englewood and Chicago electric storage battery road, and now, that the results of carefully executed efficiency tests have been made available, we take pleasure in presenting below some of the results and conclusions of these tests to our readers. During last summer over twenty motor cars were operated, often with trailers, and thousands of

people were carried each day. The tests were conducted under actual operating conditions, no effort being made to obtain results better than might be expected in every day service. The engines developed a total of 232.72 horse-power; the electrical output was 186.9 horse-power, showing an efficiency of 80 per cent., the average all-day efficiency being 79.3 per cent. The log of the boiler tests shows that the steam pressure was 168.3 pounds, and that 8.22 pounds of water were evaporated per pound of combustible from and at 212 degs. F., and that the boilers developed 149 horse-power each; 62.86 per cent. of the total calorific power of the fuel was utilized. The results of the tests on engines, dynamos and auxiliaries show that 18 pounds of dry steam were used by each engine per indicated horse-power hour. The average output of each generator was 128.3 kilowatt, which was 67.5 per cent. of full load. The load factor was .82, and the watt hours per pound of coal 155.2. The cost of coal was $1.90 per ton, and its cost per net kilowatt hour .611 of a cent. The conditions of the test were not favorable, however, as the steam pressure was lower than it should have been and the vacuum was only 24.25 inches. The engines were also overloaded during the entire run and were not operated at their rated speed. The average percentage between the horse-power developed in the cylinders and the electrical horse-power delivered on the switchboard is shown to be 79.27 per cent., which is very satisfactory, and the efficiency of the generators (running 32 per cent. below their rated capacity) is 93.1 per cent. The total station efficiency from coal pile to switchboard is 5.58 per cent. As a matter of comparison we may state that the efficiency of the Chicago Edison Company's Harrison street station, producing electrical energy for .3 of a cent per kilowatt hour, is only 4.61 per cent.

To make a fair test of the batteries, 110 trips were made on one day and 123 trips on another, giving a total of nearly 3,500 car miles. The results of these tests show the following:

Kilowatt hours at switchboard per car mile, 1.37 and 1.63 for the two days, respectively; pounds of coal per car mile, 9.45 and 10.50; cost of coal per net kilowatt hour, .655 and .611 of a cent; cost of coal per car mile, .897 and .966 of a cent. It should be remarked that there was a coating of ice upon the rails during the latter part of the second day. The total number of stops during four trips was 57, and the average speed of the cars was 11.84 miles per hour. Two efficiency tests of the battery give results of 53.6 per cent. and 62.32 per cent., respectively. These results, however, show the efficiency in actual service, but do not represent the possibilities of the batteries. All these results have been arefully plotted in the form of curves, including acceleration and current curves.

While the figures given above are very gratifying, it should be stated that the tests do not demonstrate the best results that may be expected of storage battery traction and were not made for that purpose. The primary object of the test was to determine where improvements could be made, and if this is kept in mind when comparing the results with those obtained on a trolley system of about the same size, it will be seen that the cost of fuel for accumulator traction of something less than one cent per car mile is very favorable to storage battery traction. After the improvements suggested by the tests have been made, and better coal than was used on the test, at a cheaper price, has been secured, the fuel cost per car mile should be brought well within one-half cent. The batteries have operated from eight to fourteen thousand miles and are standing the service remarkably well, so that the maintenance account up to the present has been comparatively small.

The tests were in charge of Mr. George A. Damon, consulting engineer, who was ably assisted by Prof. T. P. Gaylord and a corps of students from the Armour Institute of Chicago. In conclusion we venture to express the opinion that the experience gained by the enterprising Englewood and Chicago Street Railroad Company will benefit all interested and engaged in electric street railway development, and that it will lead to further improvements in accumulators, and the more extensive introduction of storage battery traction in the United States.

Independent Telephony.

THE fortunes of "independent telephony" have been checkered up to date and bid fair to continue so in many respects and in many places. But the matter would certainly wear a different aspect if every new opposition plant, outside the Bell circle, were to present the admirable work and organization of the Detroit Telephone Company, as now illustrated and described fully, for the first time, in these pages. We are sure the article will surprise and impress many of our readers by its details of excellent engineering; but only a visit to the plant can disclose the full excellence of the staff, the work and the equipment. We have our own doubts as to the advisability of the low rates at which the Detroit company is giving its service; having known something of the reconstruction period in the Bell business all over the country; but we must bear witness to the ability with which this opposition exchange is carried on in Detroit and to the satisfaction which the citizens have so far derived from it. To say that it is creditable to all concerned is but doing it the barest justice. There are other independent exchanges in the country making fine reports. If the general average of excellence were that revealed in Detroit, the telephone situation would be the most interesting one in the whole field of electrical industry.

An Interesting Electric Railway Anniversary.

THE pace is rapid in electrical development. To-day, February 3, ten years ago, saw the start of the Sprague electric road at Richmond, Va., an event which may be truly said to mark the beginning of the commercial development of electric traction by modern methods in this country. There had been a great deal of good work done before that time both in Europe and this country, and a great many of the fundamental principles of successtul operation had already been determined or put in practice. The work of such men as Short, Field, Daft, Henry and Van Depoele in this country particularly had made a deep impress on the art and is still there in living characters. But while inventive development had gone on so rapidly here, there had come a time when the "industry" had to take shape; a "psychological moment" when some things were to be rejetced forever and others were to prove their vital fitness; an hour when capital could be attracted or again repelled for a long period, perhaps indefinitely. Mr. Sprague launched his memorable Richmond enterprise at this critical hour, and with the help of such men as E. H. Johnson, O. T. Crosby and S. D. Greene he won signally. The Richmond road was a great stride in advance; a dating point; and though it was far from perfect, capital at once recognized in its methods and in its 30 cars the actual realization of the successful, modern street railway system. To-day that system with its 15,000 miles of road and $1,500,000,000 of investment can look back over the long way it has come since Thomas Davenport first tried his little model sixty years ago, but it will now and always find the victory at Richmond one of the shining landmarks in its history.

Multi-Voltage Dynamos.

ON another page we give a description of a method perfected by Mr. S. W. Rushmore of working ordinary direct-current multipolar generators, whereby a simple machine with single commutator may be made to deliver its entire output over a single circuit in the usual way, or be instantly connected to a number of independent circuits and the voltage on each circuit independently varied from zero to maximum without the least mutual interference. The circuits may be arranged to fulfill the conditions of a feeder and main system, or one circuit may carry a lamp load while another carries a variable elevator load without the slightest interference between the two. In connection with a set of storage batteries the load on the engine may be steadied and the boosters and wasteful resistances be done away with. The system devised by Mr. Rushmore embodies principles which heretofore have not been thoroughly understood and we expect further developments in their application.

WITH reference to the Sprague motor suspension patent decision noted in our columns last week, it would seem that its scope and present value are thrown very much in doubt by those against whom the litigation has been in reality directed. A brief discussion of the points at issue, from the Walker Company, will be found in our legal notes this week, seeking to clear up the misconception which they think may possibly exist in the public mind on the subject.

ELECTRIC LIGHTING

The Practice of Theory.[1]

BY J. C. McMYNN.

THE subject of this short paper reminds me of a trolley car, for the reason that it can be turned either way and runs equally well. Whether the subject should be the "Practice of Theory" or the "Theory of Practice," I must leave for your judgment.

In the development of electrical machinery, together with the necessary steam auxiliaries, theory and practice have been the complements of each other, and neither could have reached the present stage of perfection without the assistance of the other. Theory is much more progressive, and as a usual thing precedes practice, for practice paves the way, and lays the track, and makes it possible for the practical man to become a factor in the engineering profession.

The object of this paper is neither to praise nor decry theory or practice, but to simply recall to your minds the close relations existing between the theoretical man and the practical engineer; to a certain extent we are all theorists, for we have our own original ideas and fancies, and oftentimes the engineer who prides himself on being a practical man, is the most theoretical.

In my idea the application of theory to practical work is of the utmost importance to every owner of steam and electrical machinery. In construction work as well as in operation, it is most valuable. I firmly believe, after mature observation, that the educated engineer who can master practice as well as theory, is the one who will rise above his competitors in the future. Yet, do not understand that by "educated" I mean necessarily a college graduate. A man who can master the laws of mechanics, and can conquer mathematics by his own exertions, is deserving of more credit than one who was sent to college and learned simply because it was pounded into him.

Nearly every modern machine is an example of practical application of mechanics and design to theoretical ideas and discoveries, which thus become mechanical laws. In a certain way, theory is the foundation and practice the structure of an engineer's attainments. The deeper and more substantial the foundation, the higher and more imposing can be the superstructure; the more substantial the foundation, the more resistance will the structure have, to either the winds of adversity or the more dangerous gusts of flattery and adulation.

The Present Efficiency of Incandescent Lamps.[1]

BY JOHN E. RANDALL.

THE present efficiency of incandescent lamps for central stations lies somewhere between 3 watts per candle power and 3¾ watts per candle power. At the Detroit meeting of the National Electric Light Association, in 1887, a 1½ watt lamp was described. Every investigation of claims for extremely high efficiency has shown that there was some hocus-pocus; either the candle was of the wax taper variety, or the watt was not one of the family that James made famous, or else the lamps didn't live to tell the tale.

Finally the people forgot about the 1 watt and the 2 watt lamp, and concluded to take what they could get, which might be anything from 3 watts to 5 watts, depending upon what the maker had ready to send. It really was a matter of small moment whether the lamps were 3 or 5 watts per candle since they all went to 5 watts the next day after they were placed in circuit.

This state of affairs has continued, with some improvement, until a comparatively recent date. It was found by authentic tests that lamps whose initial efficiency was less than 3 watts per candle power would not last a reasonable time on commercial circuits. This set the maximum limit of efficiency. The minimum was set by what the people would accept and it was placed at 4 watts. More recently all energies have been exerted to produce types suitable for the various kinds of uses. We have now the highly efficient central station lamp, the isolated plant lamp, and the railway type, besides numberless modifications for special uses.

Among the lamps in the Franklin Institute tests was one Weston tamadine —16 that maintained its brilliancy and gave most excellent life. Since then the cellulose filament has been brought to a degree of perfection far surpassing the prototype. While made by a process differing from Mr. Weston's the present filaments possess all the good features to be found in this early lamp and have outgrown most of the poor ones. Upon the quality of this cellulose filament I base a claim that the present efficiency of incandescent lamps is better than it ever has been, and is so much better that the lighting industry is to be congratulated.

The incandescent lamp is still a filament of carbon of high resistance hermetically sealed into an exhausted glass globe, with conducting wires passing through the glass. Its quality as an illuminant depends directly upon the quality of the filament and the quality of the vacuum. The object of the vacuum is three-fold: 1. To reduce the energy expended, per unit of light emitted; because of the heat lost through convection. 2. To prevent injury to, and destruction of, the carbon by burning. 3. To prevent injury by abrasion or so-called "air washing."

When the vacuum reaches 1 part in 1,000, the loss of heat by convection of the gas becomes extremely small and, after a vacuum of 1 part in 10,000 is reached, the loss is negligible, so far as our present methods of measuring light can determine. Some years ago we made a series of measurements showing the relation between the degree of vacuum and the power necessary to produce a definite candle power from a lamp filament. The net results showed that, so far as the convection losses are concerned, the degree of exhaustion ordinarily found in incandescent lamps is better than need be.

We would naturally suppose that the residual gas was composed of oxygen and nitrogen, in the proportions found in air. The induction coil shows that such is not the case, and I believe that in a properly exhausted lamp, although no other gas may be purposely admitted to displace it, no oxygen remains. It is known that a filament will rapidly decline in brilliancy if the vacuum is low, because the radiating surface is injured, but it will not burn out. Very few lamps burn out because of poor vacuum, unless cracked, when, of course, fresh oxygen is constantly admitted.

While the effects of abrasion formerly were considered of importance, my experience indicates that, at present at least, they are of small consequence. A high degree of exhaustion, as measured by a vacuum gauge, is not the object to be attained; an unchanging vacuum is essential to the maintenance of the highest brilliancy. In the type of lamp made five years ago a positive injury resulted if the vacuum were made too high. The disintergration of the filament, due to evaporation of carbon, not only injured its surface but seriously darkened the bulb.

The vacuum does not grow poorer with age, provided the lamp is properly made and exhausted in the first place. Many think that all lamps gradually lose their vacuum. This mistaken notion was caused, no doubt, by a fault common to many individual lamps having the old form of seal at the base, and illustrates the influence which apparently unimportant details exert upon quality, as well as the necessity for wide information and extended experience in successfully making lamps. The present lamps, made by modern methods, have perfect joints, or else the leaks are so bad as to be instantly discovered by proper inspection.

The filament is the most important element of the lamp, so far as efficiency is concerned. Filaments are now made from a form of cellulose, reduced chemically to an amorphous state. The quality of the filament is determined by the thread. The process of squirting threads is controllable if proper skill, experience and appliances are employed.

In purity, density, surface polish and uniformity, the features that determine quality and maintain efficiency, the cellulose filament, properly made, far excels any other kind. A graphitic coating covering an amorphous carbon body, in a vacuum, is, so far as known, the best combination for fulfilling these conditions. The science of lamp making consists in knowing how the carbon body can be formed, how the graphitic coating can be given and how the vacuum can be produced. The art of lamp making consists in doing these things perfectly and uniformly a thousand times over every day. Whenever lamps are found to be uniform in voltage and efficiency they are found to

[1]Read before the Northwestern Electrical Association. Abstract.

be good. In all their minor features, recently made lamps are superior to those of older dates.

Another point worthy of consideration is the evolution of types suitable for the different conditions of service; one for close regulation and central stations, one for poorer regulation and isolated plants in general, one for street railways and other purposes in which, for certain reasons, the service is severe. Added to these are the almost innumerable varieties for special uses, such as window decorations and signs. Finally the use of cellulose has made the 220 volt lamp a commercial possibility.

It may be claimed that the new lamps are more delicate than the older bamboo, in that they cannot be run as long before the filament will break. I am not willing to admit that the cellulose filament is more delicate, either in transit or in service. Under identical conditions, it will live longer than any other form of filament. Furthermore, the individual life approaches nearer the average than has been the case with any other material. Any carbon filament which will not maintain its brilliancy should live to a good old age.

The best proofs of any claim are those based upon actual performance. In support of the claim that the present efficiency of incandescent lamps is more satisfactory than the past, I submit some comparisons.

In the subjoined table are results of tests made upon three classes of lamps: 1st, the 110 volt cellulose; 2nd, the 110 volt untreated bamboo; 3rd, the 50 volt treated bamboo, the initial watts per candle power were nearly 3.2 for all. The bamboo represent their class, both the 110 volt and the 50 volt having been carefully selected. The tests upon these were a part of a series upon a large number started in groups of various initial watts per candle, and their results are consistent with those of the entire test. The tests were carefully conducted with the best facilities. They may be considered reliable. Both lamps were at one time extensively used and well regarded.

The figures shown for the cellulose lamps are the combined results of a number of tests made at various times and places and by different persons but evidently made under similar conditions so far as regulation is concerned. There is excellent agreement, not only in averages but in individual cases, both in candle power and in watts per candle power. The oldest tests which were made over three years ago, show the poorest results. This fact suggests a gradual improvement in the quality of the cellulose lamp. All the lamps entering the tests were samples of commercial lamps taken at random from large lots. No claim is made that the results are remarkable. I believe that they can be relied upon to represent faithfully the present efficiency of the incandescent lamps supplied for central station use.

AVERAGE C. P. AND W. PER C. P. OF BAMBOO AND CELLULOSE LAMPS DURING VARIOUS LENGTHS OF BURNING.

The remarkable feature is the close agreement between various lots made at widely different times. This feature is the criterion of quality. Upon it depends the successful introduction and use of the highly efficient lamp. I believe that they can be relied upon to represent faithfully the present efficiency of the incandescent lamps supplied for central station use, because every result was used in the table, whether good, poor or indifferent. This table shows the mean candle power during a certain period of service, and not the value found at the end of the period. In the Columbia factory the accuracy of rating is considered a matter of prime importance and constant effort is made to keep the standards exact. Each lamp has a mark whereby its history may be known. The volts at which it gives its normal revolving horizontal candle power together with the current passing are marked upon a suitable label. A record of these items for each lamp is made at the same time upon a sheet. These sheets are the indices of uniformity in the product.

One of the largest alternating stations in the country has, by substituting the highly efficient cellulose lamp for the low economy silk and bamboo and by improving its regulation, been able not only to reduce the price of service to its customers, but to increase its lamp capacity over 25 per cent.

There is still one condition to be fulfilled in order that incandescent lighting may be more profitable, the voltage at the lamps must be kept everlastingly and unceasingly steady. There has been improvement, but much more is possible and desirable. Everything about lighting service is improved where regulation is improved, even the customer's temper.

Electric Lighting For Profit.[1]—I.

BY ALEX. DOW.

I SUBMIT as the first proposition that we are all in business to make a profit. I don't expect to be contradicted on that proposition, although some may wish to so amend it as to indicate that they are at present content if they can avoid a loss. As a second proposition I submit that the conditions of the electric light industry have so changed in the last few years that the opportunities of profit are limited; that the margin between earnings and expenses tends to vanish and can only be kept in view by unceasing endeavors to increase the one and reduce the other. The days have departed when a neat dividend could be paid on a small business done at high prices; and now, if a dividend is to be paid at all it must be earned by doing all the business that can be obtained and at prices set but little above the actual cost of production. As the preceding statement forms the text of this discourse I ask your attention to its repetition, as follows: I believe that the proper policy of electric light management under the conditions of the present time is to sell electric energy to every accessible user, in any shape that the user requires, and at the lowest price which will pay a reasonable profit on the capital investment.

A New Policy for New Times.—Those of you who were in the business at its beginning will recognize in this profession of faith the converse of the rule which then governed us. We used to believe in a "system," and the people who taught us to so believe, charged us so much for the experience, and the incidental machinery which we acquired, that we in turn had to collect great prices for the product sold to our customers. The rule was to get out of the business all that it would stand. Electric light was then a novelty and a luxury and a mystery, and was to be respected and paid for accordingly. Nowadays it is a thing of domestic use; the machinery for its production is sold as freely as any other machinery, the principles governing its distribution are taught to all who desire to learn; and its supply is recognized as a customary or even necessary public service exactly as is the supply of gas and water. It is proper that we should announce a policy suited to the new condition. That many have done so I know; and also that some have long been governed by just such a policy as I advocate; but there still remains, to the detriment of the business at large, some who are trying to run their affairs on the old plan. They do not profess to do so, and if challenged they may plead the old excuse—that the cost of their plant and the losses incident to its first operation have been so great as to require high prices for the energy sold. That excuse is not valid in these latter days. Taxing customers all they will stand means competition either by an opposition plant or by the municipality; and either of these means ruin to the station which is run on the old lines.

Of course I do not intimate that any member of this association is managing his business to-day after the fashion of the "eighties." But each of us knows of some plant in the next town to ours which is run just that way. That plant is going to fight it out on the old line until it is wiped out by a municipal plant; and the municipal plant will publish a report to the whole United States that it has reduced the price of lighting thirty or forty per cent. Then you and I and each of us is going to have the trouble of explaining at great length to our own particular municipal authorities why a municipal plant established in our town cannot possibly make any similar reduction.

The man who used to sell experience to us is probably to-day trying to show the ambitious city fathers of that other town next to ours how well they can serve their constituents and how much

[1]Read before Northwestern Electrical Association, Jan. 19, 1898, at Milwaukee. Abstract.

honor they can obtain from society at large by engaging their municipality in the electric lighting business. Our friend with experience to sell is not one bit more exact in his statements than he used to be long ago, and we cannot honestly say that his operations are beneficial to our business. But he is less detrimental than the man who gives him a chance to get in his work; the man who ought to be giving good service to a satisfied constituency but who is furnishing lights that are a disgrace to the "system" and its owner and trying to collect higher rates than those at which you and I are giving first-class service to our public.

What is a Reasonable Profit?—This is a much discussed question. The man in the next town believes that a reasonable profit is everything he can get; and at the other extremity of belief is the man who holds that no public service should pay a profit to any individual. Between these limits will be found the opinions of the great majority of Americans whose democratic training has taught them that the Commonwealth should not undertake any work which can be satisfactorily performed by private enterprise. Those members of this great majority who have money invested in manufacturing or in commerce recognize that a reasonable profit means something more than can be obtained by the investment of their funds in government bonds or by placing them in a savings bank; and yet something less than is hoped for when the investment is of a speculative character, involving risk of total loss of capital, such as the exploiting of a new mine or the insurance of an overdue vessel and its cargo.

I believe that after operating expenses are paid and any deterioration of the investment shown by a carefully made inventory has been made good, a dividend such as is paid by a good manufacturing business is reasonable for electric lighting. Such a dividend will necessarily vary with the line of manufacture; those concerns who manufacture a staple having a practically constant market being satisfied with a narrower margin of profit than those others where the production has to be varied from time to time and new markets developed at intervals. The same considerations govern in the electric lighting business. A station which is well established, has no ruinous competition to meet, is not threatened by municipal interference, and is not obliged to continually risk money in extensions of an uncertain character, may well pay a dividend but little in excess of the current rate of interest in savings banks. The station in which all these conditions are reversed, particularly when there is a prospect of its investment being wiped out by causes which its management cannot control, is entitled to a greater return.

There is much work to be done in the education of the public to a proper understanding of the economical principles underlying this subject. The citizen who has theories about municipal service does not apply these to his own affairs; nor will he apply to his theories the rules which govern his personal practice, until you show him that this should be done. He thinks it no harm that he should draw from the capital invested in his own business ten or fifteen or twenty per cent. in addition to a fair salary for management and any loss that is shown by annual inventory. He thinks it entirely proper that he should build up a business worth much more than its nominal capital by returning into it a large annual surplus. But he will denounce as extortionate an electric lighting company which pays a good deal less than ten per cent., and for such a company to show a surplus is in his eyes prima facie evidence of robbery of the public. He on the one hand refuses to protect the public service corporation from unlimited competition, and on the other hand demands that it do business for a rate of profit accepted only on the safest class of investment bonds.

In Europe they are more logical. They limit the price which a company may charge to its customers and the dividend which it may pay to its stockholders. They require the company to give good service to all who demand it within a certain area. But at the same time they permit no competitor to enter the same district and they provide for the purchase of the property at a reasonable price in the event of the franchise not being renewed at its term. Where they restrict they also protect. Our theorists have yet to learn that these two actions should go together and it seems to be our affair to teach them this lesson.

How Shall Rates be Made?—There has been of late much discussion of this subject at conventions and in the electrical press, and with good reason. American practice has heretofore been to make rates without sufficient analysis of cost; and particularly without attempting to make each unit of energy sold bear its proper share of the standing charges of the plant. Promising that we are to readjust rates for a minimum profit, we must do so according to a carefully considered system.

The base of any system of rate making must be analysis of the costs of production. The method of analysis which I have found most useful, is that proposed by Mr. Arthur Wright. The paper read by that gentleman at the last meeting of the National Association is doubtless familiar to you, but as American conditions usually differ from those existing at Brighton it is seldom possible to apply the short method of estimating standing and running costs which Mr. Wright found convenient, and an analysis in detail must be made. I use the following method:

Consider what the condition of the station would be if you were obliged to be ready to do the same business that you now do and during the same time, but had no customers taking current. You would have fires lighted, men on duty, dynamos turning over, lines strung and connections made to customer's premises. You would burn enough coal to keep up steam and keep the dynamos in motion, and you would have enough help for these conditions. But you would not burn so much coal as if the machinery were running at full load; and you might need less help. Your lines would be out in the weather or buried in the ground; and that deterioration which is due to time and to climate would go on just the same and would have to be made good by a repair gang. But you would not need renewals of incandescent lamps or carbons and you would not keep any men to put in fuses for customers or to read meters. You would need a manager and an engineer and an electrician just as you do now, but you would not need a bill clerk nor a collector, and you might do without an office boy. My rule is to ask whether the item of expense under consideration would continue or would cease under the conditions described. If it would continue it is a standing charge. If it would cease it is a running charge. It is clear that taxes, insurance and interest are standing charges.

Mr. Wright has shown us that it costs us a great deal of money to get ready to serve a customer, even though the customer only requires service for a single hour in a year. This amount he calls the standing charge. He has pointed out that a uniform rate takes no account of this but is apparently based on the assumption that it costs just the same to furnish current to a customer for one hour in the year as for each hour of one thousand hours in a year. He argues correctly that in making rates we should take account of a customer's load factor, and he goes on to describe an ingenious method and an ingenious device invented by himself for taking such account. Whether we adopt his device or not we must all admit the correctness of his statement of the conditions governing costs of production and we must, if we are hereafter to do business at a profit, make our rates with a due regard to these conditions.

To discuss in detail the whole theory and practice of rate making is beyond the scope of this paper. I advise each of you who has not already done so to make analysis of your costs in such manner as to distinguish between standing and running expenses. Using Mr. Wright's paper as a text book, you will find (as I did) that the labor is well paid for by the results obtained. Properly tabulated these results will show what business is profitable at any given rate or what rate should be made on any given business. My analysis showed me that I could afford to sell current to a large class of users at 4½ cents per unit, while a rate already established at 14 4-10 cents for another large class was not profitable. Now I am taking all the 4½ cent business I can find and am letting other people hunt for the 14 4-10 cent kind.

Classes of Business.—The immediate business of an electric lighting station is to supply incandescent and arc lighting, and power for stationary motors. Some small plants limit their business to lighting, and thereby avoid operating during the daylight hours. I think that this is often done without good reason. There is in nearly every village some demand for power, or such a demand can be developed by an enterprising manager. It is likely that the rates to be obtained for power will be very low, but if they will pay the additional cost of running the station during the daytime and also carry some proportion of the standing charges, these low rates may be profitable indirectly by reducing the amount of standing charges remaining to be earned by the lighting business. It is certain that interest, insurance and taxes run for twenty-four hours a day, although the plant may only operate for twelve, and if the power load will

pay half of these items, in addition to its actual running cost, it is worth having.

Some stations do not run all night. The people in the village where such a station is located may go to bed early and may not use any appreciable amount of current after 11 o'clock or midnight. But I have always found it difficult to work up a good business in residence lighting unless the plant undertook to give all night service. Apparently customers do not care to have a duplicate lighting equipment in their residences.

I am sometimes told that residence lighting is unprofitable. It surely is, if every residence that is served requires an independent transformer, and if only one residence in a dozen takes current at all. The only way to do residence lighting at a profit is to do all the lighting or nearly all that there is in a given residence district, and for this purpose the rate must be placed so that every possible customer can afford it. I have tried the experiment of low residence rates on a small scale more than once and in each instance with success. It is to be tried now on a large scale in several stations and I am certain that the experiment will be successful. The load factor of residence lighting is much better than the average load factor of many stations.

MISCELLANEOUS

The Rushmore Multi-Voltage Dynamo.

THERE has long been a demand for a large slow speed direct current generator that would deliver its output at a number of independently variable voltages, and thus meet the requirements of high generating efficiency without sacrificing the flexibility to be had where a number of smaller units are employed. Although inventors have tried for years to produce such a machine, they have heretofore met with little success and few engineers have believed that such a machine could be built that would meet the requirements of service and compete

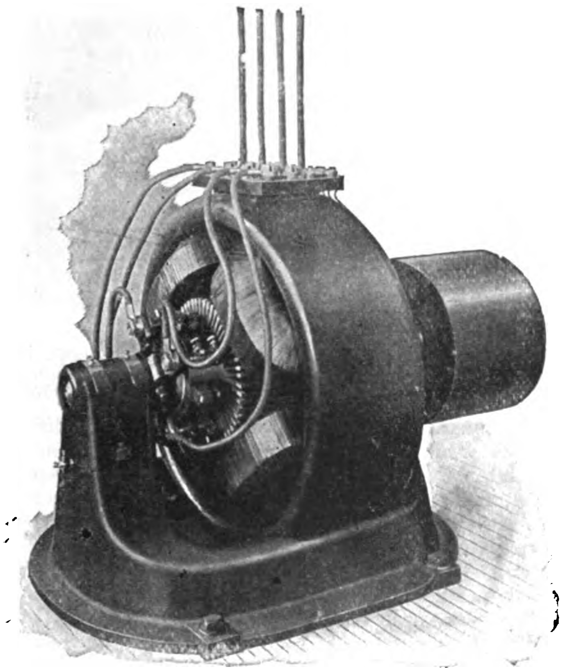

Fig. 1.—THE RUSHMORE MULTI-VOLTAGE DYNAMO.

with standard single voltage machines in first cost and efficiency of operation.

After a number of years of study and experiment, Mr. S. W. Rushmore, of the Rushmore Dynamo Works, Jersey City, N. J., has perfected a method of working ordinary multipolar generators, whereby a simple machine with single armature winding, single commutator, etc., may be made to deliver its entire output at a single voltage in the usual way, or be instantly connected to a number of independent circuits and the voltage on each circuit independently varied from 0 to maximum without the least mutual interference.

By the new method a machine will supply as many circuits as there are pairs of poles, and the voltage is varied by varying the excitation of the poles acting on the different parts of the armature. Each pair of brushes with the corresponding section of armature and pair of field poles constitute, as it were, an independent machine, and each may supply a separate circuit;

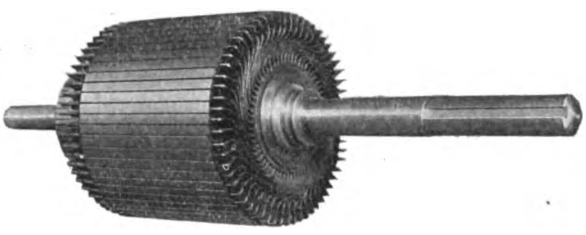

Fig. 2.

or they may be connected in groups to meet the requirements of the different circuits to be supplied.

Fig. 1 shows a 4-pole two-circuit machine now on exhibition at the Rushmore Works, and Fig. 2, the bar wound armature employed. The machine is operated in connection with a special switchboard for showing all its various applications. When brushes of the same sign are connected together on a single circuit, the machine will deliver its entire output in the usual way. To show how the machine will fulfill all the conditions of a feeder and main system, one pair of brushes

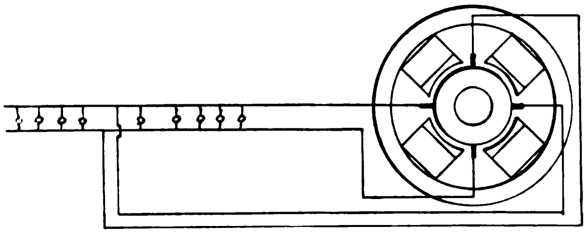

Fig. 3.

is connected to a water rheostat taking 125 amperes at 110 volts, while the other pair is connected to the same rheostat through two smaller rheostats corresponding to the resistance of a feeder. The voltage is then raised on the second pair of brushes to as high as 150 volts to deliver 125 amperes more to the main rheostat, thus overcoming a drop of 40 volts on the feeder. This is shown diagrammatically in Fig. 3.

In another experiment the machine carries one-half the full load on one pair of brushes at 110 volts, while the other pair is connected directly to the brushes of a separately excited elevator motor, and the motor is started and stopped and run at any speed and in either direction by varying the e. m. f. supplied to it by the dynamo; and although this variation is all the way

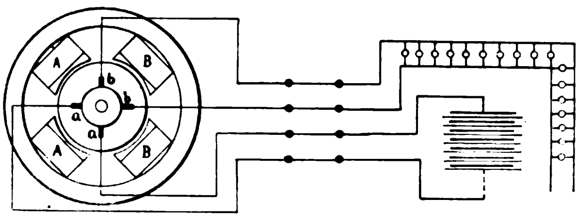

Fig. 4.

from 0 to maximum in sudden jerks, there is not the least interference with the lights on the other pair.

In connection with storage batteries the machine may run in parallel with the cells at full load, and at light load one or more of the pairs of brushes may carry the load while other pairs are connected to the battery, as shown in Fig. 4, and the voltage increased to any amount required for charging, thus doing away with boosters and wasteful resistances.

When the battery is employed to steady a fluctuating load,

the cells are connected to one or more pairs of brushes, as shown in Fig. 5, and by means of series coils on the poles acting on the sections feeding the battery, and arranged to oppose the shunt winding, the battery will automatically charge and discharge, as required, to keep the load on the engine constant at all times.

The same machine was shown in operation as a motor dynamo taking current at one pair of brushes and running at constant speed, and delivering current from the other pair, the voltage on the second or dynamo pair being varied from 0 to maximum by a rheostat in the corresponding field circuit, thus having all the advantages of a motor driven dynamo with better efficiency and without the extra cost of two machines.

Brushes are fixed and there is no sparking, even though current exceeds 50 per cent. overload over the whole range of voltage.

The principle on which the machine operates is similar, in

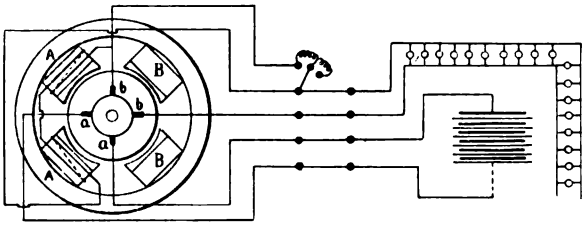

Fig. 5.

some respects to that of the Rushmore multi-circuit arc dynamo described in The Electrfical Engineer a short time ago, which consists in collecting the current from the armature in such a manner that the armature flux does not affect the strength of the poles under which current is directly collected.

This is shown in Fig. 6, which illustrates diagrammatically the course of the armature flux in a 4-pole machine, with ring armature, with current taken from one pair of brushes only, the field flux being omitted. In the diagram it is assumed that the total armature flux is four lines. It will be seen that two of the lines will circulate across the pole under which the current is directly collected, while the other two lines will pass through pole N′ in a direction opposing the field lines, then around the field ring and through pole N″ in a direction to assist in its magnetization, thus completing the circuit.

In this manner the effect of current in the armature through brushes a and b is to weaken pole N′ and to a like amount strengthen pole N″, while poles S′ and S″, under which current is directly collected, are unaffected. When the loads on both pairs of brushes are equal, the distorting influence due to one

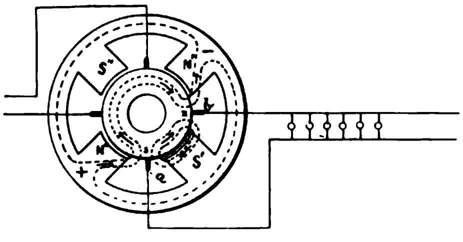

Fig. 6.

current is equal to and neutralizes that due to the other, and there is then no interference and the machine acts exactly the same as if operated in the usual way on a single circuit.

Various methods have been tried by Mr. Rushmore of winding series as well as shunt compounding and opposing coils on the poles to neutralize the effects of the armature currents, but as there is no interference whatever with the proper working of the machine when the currents are collected directly under only the unaffected poles, such devices have been discarded.

With a lap wound drum armature the distribution of the armature flux is more complex, as the current collected from a single pair of brushes passes before both poles of each pair.

All the poles in a four pole machine are affected, but as the current from each pair of brushes strengthens one of its poles as much as it weakens the other, there is no interference, and thus the only difference in the machine is that the armature must be of the multi-circuit or lap wound type.

"The Akron" Multipolar Generators and Motors.

THE gradual tendency of intelligent dynamo designs towards the ideal type of dyanmo which shall embody in one machine all of the fine points of construction, which previous experience has brought out is clearly shown in the new Akron multipolar apparatus manufactured by the Akron Electrical Manufacturing Company, Akron, O., and which is herewith illustrated.

The dynamo has a cast iron field yoke with laminated steel magnet cores and soft steel pole shoes, thereby giving an ideal, magnetic and structural condition, the laminated cores having a great capacity for magnetism and responding readily to the magnetizing influence of the coils encircling them, the cast iron makes a perfect welded joint between the cores and yoke, while the yoke has a sufficient cross section to add beauty to the design and rigidity to the whole frame, at the same time using only metal enough to provide for the magnetic circuit required. The soft steel pole shoes distribute the magnetic lines evenly over the armature, while the cross section of the cores is kept as small as is compatible with efficient results, thus reducing the copper losses in the field as much as possible. The armature is built up of fine laminations divided into three or more sections by small brass spacers having radial arms to create a blast of air through the core openings thus formed and across the ar-

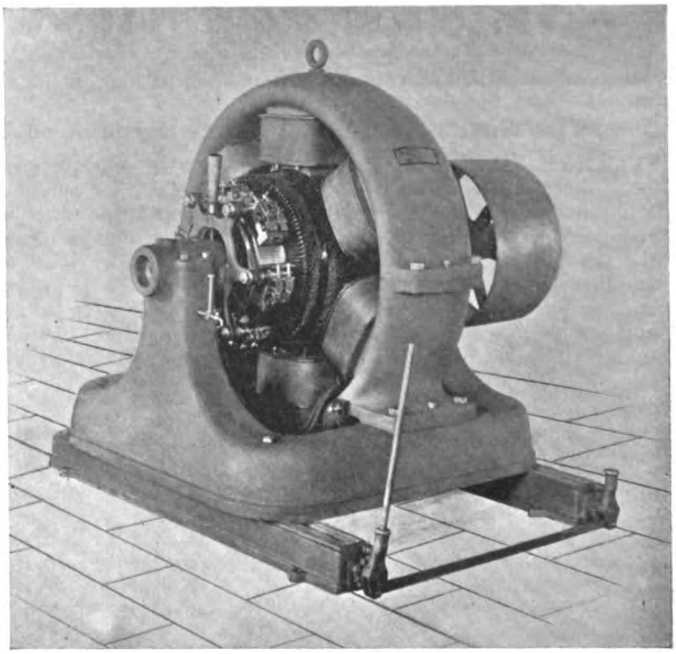

FIG. 1.—"THE AKRON" MULTIPOLAR BELTED GENERATOR.

mature winding. The spider which carries the core is of cast iron with radial arms arranged so as to admit air freely through the ends and force it swiftly through the passages formed by these spacers and the end flanges which also have radial passages for the air. This construction ventilates the armature perfectly and increases the radiating capacity enormously, keeping the temperature down far below the normal practice, and allowing heavy and continued overloads without injury to the dynamo. The machine-formed windings of the armature are perfectly formed, then insulated by hand and embedded in troughs made of mica, paper and press board.

The commutator is made up of drop-forged bars with India mica insulations put together at a high temperature and under enormous pressure so that it is impossible to move the bars when once it is assembled and turned true. The radial feed carbon brushes have large bearing surfaces on the commutator which make them run almost noiselessly and cool and are connected at the top by means of flexible copper strips to the brush holder body thus making a positive, metallic circuit from the commutator to the dynamo's terminals and being highly polished brass holders, they also add materially to the beauty of the apparatus. The bearings are self-oiling and self-aligning securely held in pedestals cast integral with the base frames, while the belted units are provided with sliding base rails having

convenient ratchet screws attached for tightening and loosening the belt. The generators are, taken as a whole, neat and pleasing in design, thorough in construction and so conservatively rated that they may be operated continuously under 25 per cent. overload with temperatures not exceeding 50° C. above the sur-

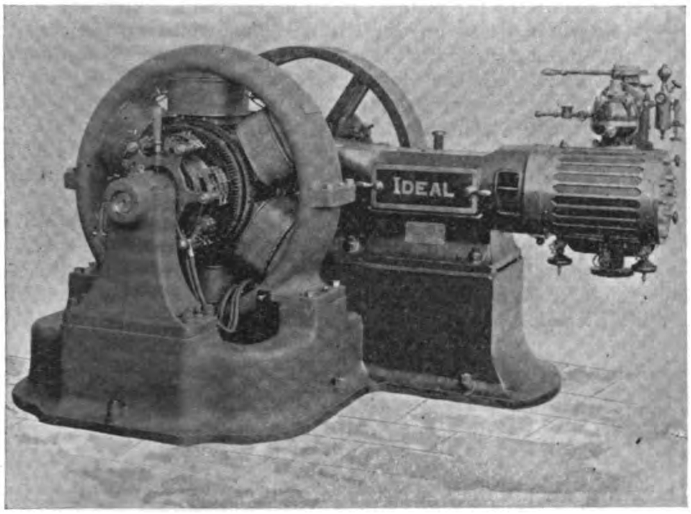

FIG. 2.—THE AKRON MULTIPOLAR DIRECT-CONNECTED GENERATOR.

rounding atmosphere and with temporary overloads of 50 per cent. without injuring them in any way. They are made for direct connected, slow, and moderate speeds and average in size from ¾ k. w. up to 300 k. w. in the generators and from 1 h. p. to 400 h. p. in the motors.

MR. FRANK A. ROGERS has resigned his position as general manager of the Card Electric Company, Mansfield, Ohio, after having served in that capacity for the past two years. It will be remembered that Mr. Rogers was formerly connected with the Brush Electric Company, Cleveland, Ohio, and was in their service continuously for fourteen years; and latterly with the Short Electric Railway Company. This is certainly a remarkable record and Mr. Rogers has the best wishes of his numerous friends for his success in whatever field he may enter.

Electrical Transmission in the Factory of the Western Wheel Works, Chicago.

THE WESTERN WHEEL WORKS, at Chicago, are just completing changes that will result in the driving of practically their entire plant by electric motors. Some idea of the magnitude of the factory can be gained from the information that its present capacity has an output of between seven and eight hundred bicycles in ten hours, and that when working full force 1,800 hands are on the pay roll. It occupies a majority of the space of a large city block, at Wells and Schiller streets, and consists of a number of buildings built or acquired from time to time as the business grew.

The present electrical transmission to the various departments of the factory which has taken the place of belts is not the result of any great and radical changes, but has been rather a natural outgrowth of the conditions. The time came when the factory plant had to be enlarged, and it was an easy matter to put in electric motors to drive the machines in the additions rather than go to the trouble and expense of putting in a lot of new belting and shafting to transmit the power to the various departments.

The general plan is not to drive each machine with a separate motor (as this would be expensive and wasteful with the hundreds of very small machines used in a bicycle factory), but to have one or more motors to drive the shafting in each of the numerous departments. This does away with the shafting running from one part of the plant to another and also abolishes the wasteful nuisance of belting vertically from one floor to another. The greatest saving, however, is during seasons of the year or hours of the day when some of the departments, or parts of departments, are not running. By shutting down the motor or motors running shafting not needed, all the loss in running unnecessary shafting is done away with, while formerly the entire friction load of the plant had to be carried as long as the engines were running.

On account of the growth and changes in the works it is impossible to tell exactly what the saving has been by the improvement. Mr. Geo. D. Van Tassel, chief engineer of the plant, and to whom is due the credit for its excellent arrangement and condition, states that previous to the introduction of electric transmission indicator cards taken from the engine showed a friction load of 50 per cent. The friction load with electrical transmission is, of course, more variable, but Mr. Van Tassel thinks the saving in cost of power for the factory is at least 10 or 12 per cent., although for the reasons stated no absolutely accurate figures can be obtained.

The central generating plant of the Western Wheel Works consists of two Heine water-tube boilers furnishing steam to two direct-coupled units. Each of these units comprises a Westinghouse compound engine running 261 revolutions per minute and a Westinghouse 125 volt generator. The rated capacity of these units is 430 h. p. each, but 530 h. p. has been lately obtained in emergencies by raising the steam pressure to 185 pounds. The generators are compound wound to provide for a small line loss of about 3 per cent. The switchboard is the regular type used by the Westinghouse Company for railway work. The wiring is a splendid example of good workmanship and intelligent design of circuits. Open cleat work is used throughout and extra precautions are taken at switches and fuse blocks to prevent crossing of wires.

The following is a list of the motors in use. A few of the larger machines were formerly used as dynamos before the present direct connected plant was built.

Two 65 h. p., one 25 h. p., one 50 h. p., and one 5 h. p. Mather motors; six 30 h. p., two 20 h. p., one 35 h. p., one 40 h. p., and three 10 h. p. of the Gibbs type; one 75 h. p. and one 7½ h. p. General Electric; and a 25 h. p. Westinghouse motor. A total of 642½ h. p.

Every motor has an automatic starting rheostat, and all care of the motors is under charge of the chief engineer's department. Whenever a motor is automatically cut out it is indicated by an annunciator drop at the central switchboard. It will be noticed that in many cases there are several motors to each department, the obvious advantage being that when the works are not running full force, part of a department can be shut down.

Visiting engineers will find a warm welcome at the hands of Chief Engineer Geo. D. Van Tassel who will, we know, extend every reasonable courtesy.

The Electric Headlight not an Element of Danger.

Officials of the Peoria and Eastern Division of the "Big Four" Railroad have made a test of an electric headlight, the Indianapolis "News" reports, to determine whether or not it is true, as some railroad men assert, that the use of a powerful headlight adds an element of danger. It was claimed that the reflected glare from the surface of the switch lamp lens is often so great that it entirely overpowers the light coming from the lamp, and will show apparently white light to the engineman, while the signal may be standing at red or green. Just the contrary result was obtained in the Western test. A green light, the most difficult to distinguish, was plainly visible at a distance of half a mile, and the red lights seemed to be magnified, being clear-cut in contrast to the pure whiteness of the electric headlight. The engineer, who has ridden behind an electric headlight for

twenty months, said that he had not the least difficulty in distinguishing the different lights on the road. It seemed to him that by contrast the colors on targets were made more distinct by the electric light.

Third Rail Successful in Severe Tests.

The superintendent of the New England Railroad says that the present third-rail system on that line will be extended from New Britain to Bristol before May, and the run between Hartford and Bristol, eighteen miles, will be made in thirty-five minutes. The third-rail line now in operation has just stood successfully the test of a severe ice and snow storm, losing but one trip between Hartford and New Britain during a day, but has yet to be tested by a heavy snow storm. It is stated officially that the New England Road had not decided to put on the composite between Hartford and Rockville to compete with the newly opened trolley line between those cities.

Thompson Electric Conduit System.

A PATENT has just been issued to R. F. Thompson, of Alexandria, La., for an electric railway conduit system embodying a very ingenious device for protecting the trolley wires from the seepage water that usually drops from the walls of the conduit or the water that passes in through the trolley slot. He accomplishes this object by means of two chambers of inverted trough shape, one chamber being located on either side of the trolley slot. The side walls and roof of these chambers are air and water tight, thus preventing any water from leaking into the same, and the only manner in which water can enter the chambers is by means of the bottom when the conduits become flooded, and in that event the water cannot rise to a sufficient height to reach the trolley wires, which are suspended from the roof of the chambers, by reason of the pressure of the air confined in the upper part of the chambers. When the grade changes, air and water tight partitions or diaphragms are provided, one in each chamber, with suitable means for permitting the trolley or plow to pass under the partitions. The patent was issued on January 11, 1898, its number is 597,036 and it appears to be one solution of the problem of insulating bare conductors in electric street railway conduits under all conditions of flooding of streets.

A Spiral Electric Railway For Niagara.

IT is intended that a great spiral railway, operated by electric power from Niagara Falls, shall be to the proposed Pan American Exposition, to be held on Cayuga Island, Niagara Falls, what the Ferris Wheel was to the World's Fair and what the Eiffel Tower was to the last Paris exposition. General plans for this conception have been made, and the details are being worked out. The basis for the railway is to be a huge circular tower of steel frame work, 500 feet high, around which, like the thread of a screw, the spiral railway will run supported on powerful brackets securely joined to the frame work of the tower. The tower will have a diameter of 80 feet at the bottom and the taper will be 30 feet to the 400 feet level, giving a diameter at that point of 50 feet. Around this tower the railway will run, rising 40 feet to the complete circle, thus passing 10 times around the tower in reaching the 400 feet level, where there will be a platform, which will be the terminus of the line. A ratchet rail will be used for the cars to make the climb on the same principle as the ascent of the Mount Washington and Pike's Peak roads. The grade of the road will be from 17 to 25 per cent. Protective devices will be used to assure safety, and it is expected that passengers on the spiral railway will be better protected than those on electric or steam railway trains. When the passengers are ready for the trip they will be seated facing outward, away from the tower, and thus the view will grow better and broader as the car ascends. Far away into Canada, up the river to Lake Erie, down to Lake Ontario, across one of the most beautiful sections of country to be found in the world, the eye will go with delight. The cars will never meet or pass except on opposite sides of the tower, the two tracks being erected on parallel but independent spirals.

At night the whole structure will be outlined in electric lights. Up and down the cars will move glittering with incandescent lamps, while from the top of the tower a powerful searchlight will illumine the falls, rapids and the exposition grounds. Above this still, a great glass globe will shine with light from within. The idea was conceived by George A. Ricker, chief engineer of the Gorge road at Niagara.

The Chicago and Englewood Storage Battery Road.

THE results of the tests of this pioneer road, which are discussed in detail on our editorial page reflect great credit on all connected with the management and equipment of that road. Of the former we may mention G. Herbert Condict, general manager; Hugh Hazleton, in active charge of the power house; H. B. Quick, superintendent of track construction; B. J. Arnold, consulting engineer of the company; and J. H. Vail, the well known electrical engineer of Philadelphia. The boilers were installed with the Roney stokers, by the Heine Boiler Company; the triple expansion condensing Willans engines by the Bullock Manufacturing Company; the generators by the Walker Company; the pumps and cooling tower by Henry R. Worthington, and the storage battery equipment by the Electric Storage Battery Company.

MECHANICAL

Physical and Chemical Properties of Volatile Oils in Boilers.[1]—I.

BY W. H. EDGAR.

NOT having written a paper, I will speak on the subject of the use of volatile oils, hydrocarbon, kerosene and oils of that nature, in the steam boiler. I do not believe there are many cases in this country where we get petroleum or other oils in our feed water supply, but the general laws of nature are such that our waters are heavily impregnated with lime and magnesia, which are the main ingredients, the scale forming salts, which form an incrustation in the steam boiler, which incrustation is a poor conductor of heat as compared with iron, so that we are forced to look around for something to counteract the evil effects of this incrustation and to get rid of it if possible; so that has led us to put most everything into our steam boilers and among the different reagents employed have been volatile oils. These volatile oils, including turpentine and oils of that nature, are all hydrocarbons and when they have been put into steam boilers have caused a corrosion or general eating and deleterious effects upon the boilers from their use.

There are two ways of looking at this subject of incrustation and its proper antidotal reagents. A boiler is very much like the human system: we are liable to injure it and we are liable to put something into it where the after effects are worse than the disease; so we must take up both sides of the question. Now, I want to bring out a few points about volatile oils and kerosene. Kerosene is a light distillate hydrocarbon and has been used very extensively throughout the country, or tried here and there, and dropped for one and another reason, and I will offer these suggestions and take up these points without any personal motive whatever, for I have none; but I will just simply take up the evil effects of kerosene and petroleum and their different distillates. Kerosene pumped into the steam boiler with the object of converting the incrustation into such form that we can readily wash it out, or prevent its formation, I will consider in the first place. Kerosene is a hydrocarbon. If we had a carbonhydrate, an animal oil, we would get an oleate radical and could possibly get the oleate of lime or oleate of magnesia, which, however, would not help us out; but we could get a chemical reaction from carbonhydrate, having a combining acid radical there; but in the hydrocarbons we have no possible acid radial; we have not the base; we have not the combination that will take the place of either base or an acid radical and we get no chemical reaction whatever and the action of the kerosene is purely mechanical, following the laws of capillary attraction. If I dip a blotter into water, the water will run up the side and penetrate the blotter; if the blotter is set over a tumbler of water, the water will penetrate through the sub-

[1]Abstract of an address before the Northwestern Electrical Convention, Milwaukee, Wis., January 20, 1898.

stance of the blotter; and if you play a hose on a brick wall the moisture will penetrate to the other side. Now, kerosene, being a light volatile oil, will penetrate everything of a porous nature such as lime, magnesia, etc., and will penetrate to a greater extent and more rapidly than water. The scale incrustation in the boiler will be softened, will be penetrated by this kerosene, due to the laws of capillary attraction, the scale being porous, the kerosene will work through to the iron and when it comes in contact with hot metal, the oil will run back of the sheet of the scale between the scale incrustation and the iron, and when you shut your boilers and draw your fires and let out your water, your boiler contracts, the iron contracting and expanding with the application of heat. Now, you have put a substance of different physical properties, of a different nature, between your lime and magnesia incrustation, and your iron sheet or plate. The lime and magnesia, little particles of them, will attach themselves to the sheet, due to the general affinity that they have for hot metal; they cling very tenaciously to the iron and when this substance comes in between, you have lessened that adhesive property and the incrustation is not adhering as tenaciously, and consequently being a non-conductor and not expanding and contracting uniformly with the iron, it is more readily scaled off and you get a great quantity of this broken scale from the continued use of a volatile oil such as kerosene. The kerosene does not change the chemical composition of the scale, its action is purely mechanical.

Now, there are other points to be looked at. Kerosene volatilizes in the steam boiler; you get probably a third over with your steam; it passes off immediately and begins to come over from above 150 degrees to 300 degrees Fahrenheit. (I was going to bring a little retort and a receiver up here, but thought it would be in the way and we would not be able to set it up.) This kerosene that passes over, constitutes hydrocarbon distillate and your steam is hydrogen and oxygen, and you know the evil effects from condensation in a steam plant; you know that every year you have in your heating system to put in a few more nipples or an elbow here and there. When you put in a light volatile oil of a hydrocarbon nature, you intensify that action and you get a series of oxydizing hydrocarbon reagents that will intensify that general pitting and grooving 1,000 per cent., that is, you will get the general eating through of the joints and connections probably ten times as quick as you would otherwise. Besides that, the kerosene is carried over into your cylinders. It is a part of the cylinder oil in the first place; they all come from the petroleum, except the animal oils. The kerosene is a solvent for them. It dilutes your cylinder oil; it has a tendency to change its lubricating properties just that much, and with the hydrogen and oxygen of the water and the compound formed in the distillate, you will get blackening of your piston rods and the deleterious general oxidizing effect on your rings, and if you have a metallic packing you will have hard work keeping your packing in your engine. From these same distillates, these same products formed in your distillation, you will have the pitting and the general eating through of all the threads of your joints and connections, through your entire steam system; not only that, but the part that is left in the steam boiler and the part that goes through your scale and reaches the iron cannot stand that high heat. It is carbonized; it is all decomposed, and in the carbonizing of the hydrocarbon oil in the presence of iron or against the iron sheet, you are going to carbonize your iron and you will have there a blistered appearing spot where the iron has been carbonized; it will be of a blackish, blistered appearance, and you will get that action all through the water submerged part of your boilers; and you will never get all your scale out with kerosene; you will never get more than a third, and those who are using kerosene and claim it is working fine, simply look at the scale that they take out and do not look into the boiler to see what is left. In my travels I have had some of my best friends tell me that they have used kerosene and their boilers are clean, their system is in good shape and I have gone down to their plants and looked around, and in the steam system from the boilers to the engine, I have seen the little leaks, and when this leakage does start in and the flange gives out and you have to put a new one in, in taking that apart you jar the whole system and bring to sight more leaks where your piping is half eaten through and almost ready to leak. Of course, an old plant will show up leaks in a few months or a year, but a brand new plant will disclose leaks in time if you continually use kerosene.

SOCIETY & CLUB NOTES

American Institute of Electrical Engineers.

The one hundred and twenty-first meeting of the institute, which was held at 12 West Thirty-first street, New York, Jan. 26, was devoted to the discussion of the question of Standardizing Generators, Motors and Transformers. The discussion was opened by Mr. E. W. Rice, Jr., and was participated in by Messrs. Lozier, Kennelly, Wolcott, Hutchinson, Moscrop, Lieb, Dunn, Coho, Pattison, Henshaw, Steinmetz, Mailloux and Osterberg. The appointment of a committee to consider the question was suggested, and subsequently the whole matter was referred to the council for such action as it may deem proper.

At the meeting of the council in the afternoon the following associate members were elected: Chas. R. Bangs, special agent, American Telephone and Telegraph Company, 15 Dey street, New York; M. C. Beebe, assistant in electrical engineering, University of Wisconsin, residence, 271 Langdon street, Madison, Wis.; Hugh Thomas Brown, superintendent of electrical department, Selma Gas and Electric Company, Selma, Ala.; Edward P. Burch, electrical engineer, Twin City Rapid Transit Company, 517 Sixth avenue, S. E., Minneapolis, Minn.; Eben Clinch Crocker, electrical engineer, American Ordnance Company, 29 Harriet street, Bridgeport, Conn.; Albert B. Elias, electrician, Davis Coal and Coke Company, Thomas, West Va.; Alex. Stanley Garfield, engineer, Thomson-Houston, Cie 27 Rue de Londres, Paris, France; Chauncey Graham Hellick, electrical engineer, The Chicago Telephone Company, residence, 193 Dearborn avenue, Chicago, Ill.; Jacque L. Morgan, electrical inspector, Kansas City Fire Department, residence, 1702 Locust street, Kansas City, Mo.; Herman A. Prosser, electrician, Baltimore Copper Smelting and Refining Company, Keyser Bldg., residence, 1222 Madison avenue, Baltimore, Md.; John Joseph Swann, assistant editor, "Engineering News," 220 Broadway, residence, 347 West Thirty-fourth street, New York; C. Walton Swoope, instructor, electrical engineering, Spring Garden Institute, residence, 12 North Thirty-eighth street, Philadelphia, Pa.; Jin Tachihara, General Electric Company, residence, 106 Union street, Schenectady, N. Y.

The Indiana Mutual Telephone Association.

THE annual meeting of this association was held at the Bates House, Indianapolis, Ind., on January 19, 1898. E. H. Andress, of Lafayette, president of the association, said that the independent telephone business throughout the State is on the increase, both in the number of subscribers to older exchanges, and in the number of new exchanges which are being put in. He said that in the beginning the home companies were regarded by competitors as short-lived, but the independent organization had now become a factor which is outgrowing the Central Union Company in strength. This showing indicated that home companies should continue to "stay in the thick of the fight." It was also stated that where a home company and the Central Union are at war the people are inclined to the home organization.

George W. Beers, of the Home Telephone Company, of Fort Wayne, says the company has 1,400 subscribers and charges a rental of $36 a year for telephones in business houses and $24 for those in residences. Where a subscriber has both, the rate is $48 a year for the two. He said the company has seven hundred miles of wire reaching other towns in Indiana and Ohio.

A committee was appointed at the last annual meeting to confer with similar committees of independent associations in Pennsylvania and Ohio. This report showed that the independent enterprises were carried on in these three States named to a greater extent than in others. In the three States there are 250 independent exchanges, with more than 100,000 subscribers, and the capital invested is more than $5,000,000. The report said that the demand upon home companies is now for more extended, or long distance service. That this end might be reached it was stated that in the three States organizations are forming. To further this work, committees from the three States had been appointed. That from Indiana consists of E. H. Andrews,

George W. Beers and Hugh Daugherty. The committees had conferred with the Western Union and Postal Telegraph Companies, with the object of forming an alliance of some kind whereby the long distance lines might be established. But the possibilities are so remote, the committee said, that about the only way to obtain the desired result is to incorporate the independent exchanges of the State into a company, with sufficient capital to build the connecting lines. It was recommended in the committee's report that this movement be taken up at once and developed as rapidly as possible.

The following officers were elected for the ensuing year: President, E. A. Andress, of Lafayette; vice-president, J. S. Stone, of Rushville; secretary and treasurer, A. E. Reynolds, of Crawfordsville; assistant secretary, W. H. Ernst, of Blumton. Executive Committee: E. H. Andress, J. S. Stone, A. E. Reynolds, George W. Beers, of Fort Wayne; C. M. Zion, of Lebanon; Elbert Shirts, of Noblesville; A. E. Ramsay, of Crawfordsville.

The Civil Engineers' Club of Cleveland.

The semi-monthly meeting of the club was held in its room in Case Library Jan. 25, 1898, at 7.45 P. M. President Ritchie in the chair. Mr. Samuel T. Dodd read a paper on the subject of "Power Consumption on Electric Railroads." He discussed the resistance developed by moving cars, and reviewed the formulas which have been in common use to express this resistance, comparing the results obtained by them with a number of recent instances upon electric railroads. He concluded that experience shows that the old formulas, while giving results rather high at low velocities give too small resistances at high velocities when applied to electric motors. The author also discussed tne question of acceleration and the power required to bring the car to a certain maximum velocity and the number of seconds in which this may be accomplished. He adduced instances from the practice of several of the inter-urban roads about Cleveland and showed that about 400 pounds per ton was the maximum horizontal effort to be expected from the electric motor. The paper was accompanied by a number of diagrams and tables illustrating the subject.

Engineers' Club of Chicago, Ellicott Lecture on Fire Alarms.

City electrician E. B. Ellicott, of Chicago, delivered a lecture on city fire alarm systems before the Engineers' Club of Chicago the evening of Jan. 28, at the rooms of the club, 1800 Fisher Building. The object of the lecture, as stated by Mr. Ellicott, was to give an idea of the workings of the Chicago fire alarm system without going far .nto electrical details. A fire alarm circuit was run into the room, and the lecutrer's remarks were supplemented by a practical demonstration of the process of giving an alarm. Assistant city electrician, D. M. Hyland, who has been connected with Chicago's fire alarm department for twenty-five years, was present and assisted in the demonstrations. The Chicago fire alarm system received quite an impetus after the great Chicago fire, and it has been constantly improved by those connected with it until there is probably none better in the world to-day.

Henry Electrical Society.

The ninety-sixth meeting of the Henry Electrical Society will be held at Columbia University, Engineering Building, Room 502, on Friday, Feb. 4, 1898, at 8.15 P. M., when A. H. Ford, E. E., will deliver an experimental lecture on "Transformers."

Third Annual Convention of the National Association of Manufacturers.

This convention, the most notable in the history of the association, was called to order in the Masonic Temple, New York City, on Tuesday morning, January 24, by President Theodore C. Search. At that time over 400 representatives of industries from the North, South, East and West filled the auditorium, including also delegates who represented the manufacturing interests of foreign countries and are here investigating American methods. The president's report contained some valuable statistics and information regarding our exports, the shipping question, the Nicaragua canal, commerce and industry, sample warehouses, technical education, reform oi the consular service, international banking, the bankruptcy law, State taxation, patents and patent laws, the metric system and the Paris exposition of 1900. The committee on languages, weights and measures submitted a report in favor of the metric system. On Wednesday and Thursday the report of President Search was discussed, and on Thursday evening over 1,000 delegates, guests and friends attended the banquet at the Waldorf-Astoria. President McKinley delivered a stirring patriotic address, in which he referred in glowing terms to the work oi the association. Conspicuous among the delegates were: C. A. Benton, Sprague Electric Company, New York; C. F. Lunkenheimer, Cincinnati, O.; James Watson, Otis Bros. Mfg. Company, Yonkers; Fred B. Smith, Ferracute Machine Company, Bridgeport, Conn.; Charles A. Schieren, Sr. and Jr., New York; Charles A. Moore, Manning, Maxwell & Moore, New York; Chas. T. Hughes, General Electric Company, East Orange; H. S. Manning, Shaw Electric Crane Company, New York; Walter L. Pierce, Lidgerwood Mfg. Company, New York; N. B. Lyons, Bullard Machine Company, Bridgeport, Conn.; Theo. F. Miller, H. R. Worthington Pump Works, Brooklyn, N. Y.; W. E. Gilmore, Edison Phonograph Works, Orange, N. J.; C. E. Bigelow, Geo. F. Blake Company, New York; C. E. Billings, Billings & Spencer Company, Hartford, Conn.; Richard Butler, Butler Hard Rubber Company, New York; F. L. Bigelow, The Bigelow Company, New Haven, Conn.; E. P. Atkinson, Charles A. Schieren & Company, New York; Franklin Phillips, Hughes & Phillips Company, Newark, N. J.; E. P. Bullard, The Bullard Machine Tool Company, Bridgeport, Conn.

Chicago Electrical Association.

AT a meeting of the above association, held at Chicago Jan. 7, 1898, Mr. H. G. Dimick read a very interesting paper on "Electrical Shop Transmission." In discussing this subject Mr. Dimick confined himself largely to the two-wire 220-volt system and motors belted to line shafting. He gave very practical suggestions for changing the equipment from belt to motor-driven, describing the switchboard apparatus required for the motor equipment, the connections on the board and the distribution of the electrical energy for power purposes. He illustrated his remarks by numerous illustrations and his treatment of the requirements of an automatic starting rheostat was thoroughly practical and exhaustive. In closing his address Mr. Dimick very aptly said: Taking all in all, shop transmission probably gives rise to as many problems of construction as any other branch of electrical engineering, and is a distinct class of work in itself, to be met and dealt with in the best possible manner, and then wait for experience to prove the need of something simpler, cheaper and better.

The spring programme of the association includes the following papers: Feb. 4, "Electricity in Ship Building," C. C. Mattison, engineer, Chicago Ship Building Company; Feb. 18, "Electricity in Medicine," E. W. Jewell, McIntosh Battery and Optical Company; March 4, "Relationship of the Hunter and Tesla Patents," A. Miller Belfield, patent attorney; March 18, "The Autobiography of a Piece of Wire," C. T. Gage, Washburn & Moen Mfg. Company; April 15, "The Electric Railway," W. R. Garton, R.R. Man., Central Electric Company; May 6, "The Enclosed Arc Lamp," J. M. Hollister, Western Electric Company.

The annual banquet will be held on May 20. The officers of the association for 1898-'99 are: F. S. Hickok, president; T. G. Grier, vice-president; E. J. Swartout, treasurer; J. R. Cravath, secretary; S. G. McMeen, J. M. Hollister and C. Wiler, directors. All communications should be addressed to the secretary, 825 Monadnock Building, Chicago, Ill.

Lectures on Electrical Engineering.

The Columbia University lectures in co-operation with the American Museum of Natural History for February will be given at the Museum, Central Park, Seventy-seventh street and Eighth avenue, on the following Saturdays, at 8 P. M.:

Feb. 5. Mechanical Sources of Energy, Prof. F. R. Hutton; Feb. 12. Generation of Electrical Energy, Prof. F. B. Crocker; Feb. 19. Transmission of Electrical Energy, Dr. A. E. Kennelly; Feb. 26. Utilization of Electrical Energy, Prof. Wm. A. Anthony. The lectures will be illustrated by slides and experiments. Tickets of admission are required. They can be pro-

cured without charge by application to the secretary of Columbia College.

PERSONAL

PROF. ELIHU THOMSON has a very interesting and complete review, in the January Forum, of the electrical advance of the last ten years.

MR. NIKOLA TESLA, according to the New York Herald, has had his hand examined by a palmist, from a photograph taken by vacuum tube light. According to the expert, Mr. Tesla, in spite of one very heavy loss, will make a great success in financial affairs and will be married twice. The line of Venus is strongly developed. This agrees with all that his friends do not know about him. The head line indicates a very shrewd and active mind.

ELECTRICAL EXHIBITION. FROM MAY-2 TO MAY-31-

Important Electrical Exhibition Arrangements.

WE are in receipt of the following from the Electrical Exhibition authorities: Aside from the fact that large amounts of space are now being taken up for the Electrical Exhibition next May, and that the flow of applications is such as to exhaust every possible and available square foot, a great deal of other preliminary work is going on quietly. A very important and interesting piece of news is the acceptance by Prof. F. B. Crocker, of the position of consulting engineer, on invitation of the management, which is desirous of associating with itself all that is best in regard to the technical side of the art. Prof. Crocker, who regards the exhibition as a highly useful means of reaching the public, is deeply interested in its success and wishful of promoting its beneficial influence in every way. His name as consulting engineer is a guarantee of good work being done under his supervision and by the construction staff in the disposition and safeguarding of the exhibits. Prof. Crocker, as president of the American Institute of Electrical Engineers and Professor of Electrical Engineering at Columbia University, represents the highest technical skill known in the profession; and the exhibition management felicitates itself upon this valuable acquisition.

In addition to this, an Auxiliary and Educational Committee has been formed to take general charge of exhibition matters other than commercial, and to co-operate with the Advisory Committee, which represents the New York Electrical Society. The Auxiliary Committee comprises men of the highest standing, all of whom intend to take an active part in the work and are now making extensive and interesting plans, of which note will be made from time to time. Mr. T. C. Martin, who was chairman of the very successful committee of the 1896 show, has again consented to serve in the same capacity. With him are associated, Prof. F. B. Crocker, of Columbia University; Prof. Morris Loeb, of the University of New York; Prof. W. E. Geyer, of the Stevens Institute of Technology; Dr. Chas. A. Doremus, of the College of the City of New York; Mr. Herbert Laws Webb, of the New York Telephone Company; Mr. J. B. Taltavall, editor of the "Telegraph Age"; Dr. Park Benjamin; Secretary G. H. Guy, of the New York Electrical Society; Mr. W. T. Wheeler, vice-president and national deputy National Association of Stationary Engineers; Lieut. G. O. Squier, U. S. A., and Mr. Thos. A. Edison, Jr., who is in charge of some special decorative and mechanical effects. It is believed that this committee enjoying as it undoubtedly will the heartiest confidence and co-operation of all, will be able to accomplish some extremely useful and memorable work in behalf of the science and industry.

As already announced, the New York Electrical Society, under whose auspices the exhibition is to be held, has already appointed an Advisory Committee entrusted with its interests, and composed of its present officers and past presidents, namely, present officers Dr. M. I. Pupin, president, and Messrs. Dunn, Sinclair, Case, Osterberg, Guy, Riker, Coho and Ker; and past presidents as follows: Messrs. F. W. Jones, Small, Pendleton, Crocker, Wetzler, Mailloux, J. W. Lieb, Jr., and Dr. C. E. Emery.

LEGAL NOTES

The Sprague Suspension Patent Decision.

The recent decision by Judge Wheeler in the Circuit Court with reference to the Sprague patent would appear to have created considerable misunderstanding. Tne broad claims of this patent includes suspending of an electric motor on the car axle at one end and spring suspending it at the other. If these claims were upheld it would be serious for all makers of railway motors except the assignees of the patent in question.

Such, however, the Walker Company point out is not the case. We quote from Judge Wheeler's opinion: "If Sprague's patent was merely for hanging and centering one end of a motor of a carriage upon the axle of the driving wheels and suspending the other by a spring from the body of the vehicle or truck, it would be shown from that case (meaning the St. Louis case) to be wholly lacking in novelty and void. He was not a pioneer here, and could have a valid patent only for what was new in his method of making the power of the electrical current turn the driving wheels."

"What was new in his method" consisted in supporting the armature bearings by a bracket fastened to the pole pieces, a device which is no longer used in railway motors. In using a motor pivotally suspended from the car axle, the Walker Company violates, its officials point out, no valid rights conferred on any one by reason of Mr. Sprague's patent, and the second feature of suspending the armature by brackets fastened to the pole pieces, the Walker Company says it does not care to use.

Judge Wheeler has issued an order suspending the injunction for 30 days, pending appeal if desired by the defendants.

THE STOCK MARKET

A Wonderfully Active January.

THE month that has just ended marks a good start for the New Year. Confidence in American securities has been one of its features. The transactions in bonds on the New York Exchange broke all records, reaching about $90,000,000, at advancing figures all around; while stocks have been equally strong and in demand. There is a remarkable ease in the money market, the banks carrying large surplus. Both the railroads and general business are in excellent shape, and Bradstreets summing up the situation remarks: "Favorable conditions in the trade situation continue to far outweigh those of an opposite character." The failures for the closing week of the month were the smallest for the last five years. Wheat is again higher.

During the week 20,454 shares of Western Union were sold, closing at 91 5-8. General Electric was stronger, and on sales of 14,305 shares advanced to 36¼. In Boston, American Bell Telephone was little dealt in, at prices from 267 to 270.

Copper is quoted at 11 cents. Heavy steel rails are $18. Lead is a shade lower at 3.60 cents, New York. Great activity is reported in the pig iron and steel markets.

THE "ARGONAUT," submarine boat, has been telephoning from under the water in Baltimore harbor to various points in Baltimore and Washington by means of 1,200 feet of insulated cable.

REPORTS OF COMPANIES

The Chicago Telephone Company.

The Chicago Telephone Company at its annual meeting on Jan. 19, 1898, reported that surplus after paying 12 per cent. dividends on its outstanding capital stock of $4,336,500 was $104,313.47. No report was submitted to the stockholders, except the following brief statement by Secretary C. E. Mosley:

	1896.	1897.
Gross earnings	$1,955,829.03	$2,072,079.55
Expenses	1,355,624.05	1,447,386.08
Net earnings	$600,204.98	$624,693.47
Dividends paid	499,224.00	520,380.00
Surplus for year	$100,980.98	$104,313.47
Capital stock outstanding Jan. 1, 1898		4,336,500.00

The following directors were elected by the unanimous vote of 38,298 shares: J. Russell Jones, John M. Clark, Norman Williams, Robert T. Lincoln, John de Koven, Byron L. Smith, Arthur G. Fuller, C. E. Perkins and William A. Jackson.

The only change was in the selection of Byron L. Smith to succeed the late George M. Pullman. The meeting adopted an amendment increasing the number of directors to eleven, and the two new places will be filled by the board.

The Central Union Telephone Company.

At the annual meeting of the stockholders of the Central Union Telephone Company, held in Chicago Jan. 19, 1898, President W. A. Jackson made the following financial showing:

	1897.	1896.
Gross earnings	$1,436,898.80	$1,333,082.37
Expenses—For administration, operating, maintenance and interest	1,156,505.44	1,091,872.74
Net revenue	$280,393.36	$241,209.63
Surplus	280,393.36	175,156.63
Added to construction account:		
At exchanges	$333,436.00	$416,942.77
For toll lines	487,004.94	271,659.39
Total	$820,440.94	$688,602.16

For the six months from Jan. 1 to June 30, 1896, there was received in gross revenue $67,213.19 from property operated in the State of Iowa, and a net revenue of $26,148.37; therefore, to make the comparison of earnings and expenditures for the years 1897 and 1896 upon an equal basis the Iowa earnings, as above, should be eliminated, since we have received no revenue from that source in 1897. The actual difference in favor of 1897 upon this basis is: Increase of gross earnings, $171,029.62; increase of net earnings, $65,320.10. The number of exchanges in operation this year is 153, an increase of 20. The number of subscribers Dec. 31, 1897, was 36,318, an increase of 4,674. The number of toll stations is 1,157, an increase of 202. The number of miles of wire in intertown lines is now 24,446. There has been constructed during the year in this class of property 2,298 miles of pole line and 9,352 miles of wire, almost the entire amount of which is of copper metallic circuit.

The following directors were re-elected by the unanimous vote of 45,895 shares: C. H. Brownell, R. C. Clowry, Arthur G. Fuller, F. H. Griggs, John E. Hudson, W. A. Jackson, J. Russell Jones, M. G. Kellogg, Robert T. Lincoln, John P. Wallick and Norman Williams.

There are 540 stockholders, and the last preceding report gave the outstanding stock at $6,605,300.

Gridironing Michigan—The Lansing, St. John's and St. Louis Railway Co.

The Lansing, St. Johns and St. Louis Railway Company have just been incorporated with a capital stock of $250,000. The company will devote itself to the construction of overhead trolley roads through the magnificent farming country of Michigan. They will traverse the following towns and cities: Lansing, St. Louis, Ithaca, Pompeii, Maple Rapids, St. Johns, and other small towns. Fifty-three miles of track have already been laid, not including side or spur tracks. The officers of the company are: M. V. Montgomery, president; Isaac Hewitt, vice-president; F. L. Dodge, secretary; A. B. Darragh, treasurer. The directors are: Jacob Stahl, M. V. Montgomery and Frank L. Dodge, of Lansing, Mich.; A. B. Darragh and Stiles Kennedy, of St. Louis, Mich.; Isaac Hewitt, Maple Rapids, Mich., and George P. Stone, of Ithaca, Mich.

Annual Report of the Southern New England Telephone Company.

The annual report of the Southern New England Telephone Company for the year ending Dec. 31, 1897, shows the following comparison:

	1897.	1896.	1895.
Gross	$594,831	$552,466	$503,716
Expenses and charges	430,677	397,444	391,814
Balance	$164,154	$155,042	$111,902
Dividends	150,000	103,491	86,250
Surplus	$14,154	$51,551	$25,652

Twenty-five per cent. of earnings came from toll-line business. The year began with 8,027 instruments in use and ended with 9,376, a gain for the year of 1,349 instruments, as compared with a gain last year over the year before of 1,020 instruments. All circuits of the company are now metallic. Twenty per cent. a year is charged off for cost of switchboards, and there have been other charges against depreciation of $18,000. The sum of $200,000 has been spent in construction during the year, chiefly derived from the new stock issued in 1897. There are now underground systems in New Haven, Hartford, Bridgeport, Meriden, Waterbury, Stamford and some smaller towns, and in New Haven and Hartford 800 subscribers take underground service directly into their houses. In the new limited service, 130,000 tokens were bought during the year. All but seven of the 168 towns in the State are now reached by the wires of the company. A test for sixty consecutive days between thirty-six switchboards of the company has indicated a total service of about 13,000,000 messages a year.

HUGO REISINGER, of New York, the well known importer of "Electra" carbons, has changed his office from 38 Beaver street, where he has been for so many years, and has taken an extremely handsome suite of offices on the fourth floor of the Bowling Green Building, 11 Broadway. Mr. Reisinger still retains his old warehouse accommodations, but has found it necessary to have larger and more commodious office facilities, as above noted.

OBITUARY

William Habirshaw.

It is with extreme regret that we note the sudden death of young Mr. Wm. Habirshaw, the only son of Dr. W. M. Habirshaw, of the India Rubber and Gutta Percha Insulating Company, of this city and Yonkers. He was taken ill with pneumonia about a week ago, and although all the resources of medical skill were brought to bear on the case, and in spite of a splendid physique, he succumbed to the disease on Sunday morning, Jan. 30. He was one of the best informed men in the wire insulation field, having enjoyed the training of his father and being closely associated with all the expert work in the laboratory at the large Yonkers factory. We can only extend our heartfelt condolence to the bereaved father and mother, in common with a host of distressed friends who had learned to admire and esteem their son, still so young and full of promise. The funeral service took place on Tuesday at St. John's Church, Yonkers, and the interment was at Woodlawn cemetery.

TRADE NOTES & NOVELTIES

"Express" Type Switchboards of the American Electric Telephone Co.

THE new "Express system" of the American Telephone Company, of Chicago, has lately been adopted by many independent exchange companies in all parts of the Union. Below we give a description and illustration of the "Express" switch-

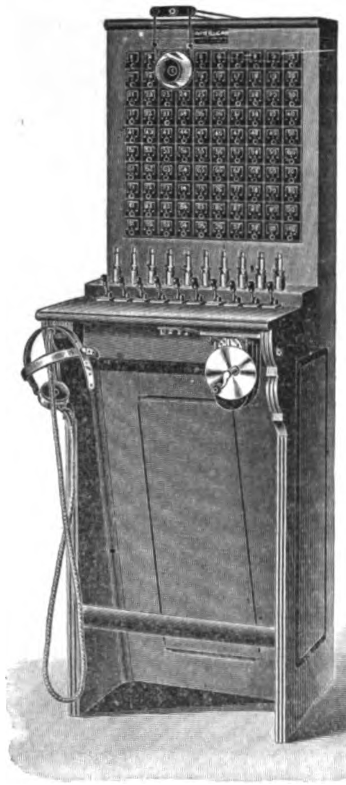

FIG. 1.—EXPRESS SWITCHBOARD, AMERICAN ELEC. TELEPHONE COMPANY.

board, which contains many admirable features of construction and ease of operation.

Each drop and jack in this board is mounted in a separate case, or shell, and hence, each of these little cases contain practically the vital and essential parts of the switchboard. The back of the board consists of a series of hardwood strips extending horizontally across the board inserted in a cabinet of the same, and each strip is of the same width as the height of the shell from top to bottom. There are ten of these wood strips and each strip is made for the insertion of ten drops. Along the front of each wood strip are run four strips of German silver. Two of these represent the generator circuits, and two the night alarm circuits. German silver springs—four in number—are mounted on the back of each of the drop cases. These represent the generator and night alarm terminals of the drop. Extending out from the back of each drop shell are also two substantial machine screws. In inserting these screws through holes bored in the wood strips, the drop is brought into its proper position in the switchboard, and the machine screws running through the board are provided with thumb screws or nuts. When these nuts are tightened, the drop is fastened securely in position in the frame, and at the same time, connection is positively and reliably made between the German silver bands or strips on the front of the wood strip on which the drop is mounted, and hence, night alarm and generator connections are made between the drop and the strip circuits.

Each 100-number section, whether equipped with full 100 drops or not, is wired for the full 100 lines, with a set of operator's instruments mounted and all circuits run, ready to connect the board to line terminals and put the same into operation without any inconvenience.

As to line connections, when the machine screws pass through the wooden strip, they also pass through a German silver punching which is provided with a lip, and when the nut is put on the machine screws, positive connection is made between these machine screws which represent the main line terminals and the German silver punching to the lip, to which is permanently soldered the line connection. Hence, the claim that a drop can be removed from and replaced in the switchboard within a few seconds' time without disturbing a single connection. As to the advantages assured in the way of accessibility of parts for inspection and repairs, this board is positively unequalled, and the great advantages in this respect are thoroughly appreciated by all its users.

All interior parts of the shell are nickeled and fully polished. Nothing but the very best German silver springs are used. Hard rubber is used throughout in providing for insulation, etc. The drops are the most sensitive to influence of magneto current of any ever made, and the drop shutter will fall where a 10,000 ohm generator is used through a resistance of upwards of 9,000 ohms.

All windings are with silk covered wire. The drop coils themselves are inserted in a non-inductive metal shell. This metal shell containing the drop is placed in the shell which contains the combined drop and jack. The plugs are of the "round" type and of the utmost durability; jacks are positive in action, allowing of no possibility of the leaving of a line open, or introduction of high resistance into the circuit owing to poor contact.

As to the method of operating the board, but three moves are required to answer a subscriber's call, restore drop shutter on line calling, ascertain the number wanted and ring the station required. The board is absolutely clear of patent infringement. The use of a clearing out drop is done away with; the main line drops act as ring-off drops. When a call is answered, the drop is automatically restored by the insertion of the plug into the jack of the line calling. When parties are connected by means of a pair of cords and plugs, when desiring disconnection, and ring-off, the drop shutters of lines connected fall, and when the plugs are removed from the jacks, shutters which are displaced by the ring-off, are automatically restored, the operator never being required to touch a drop shutter with her hand.

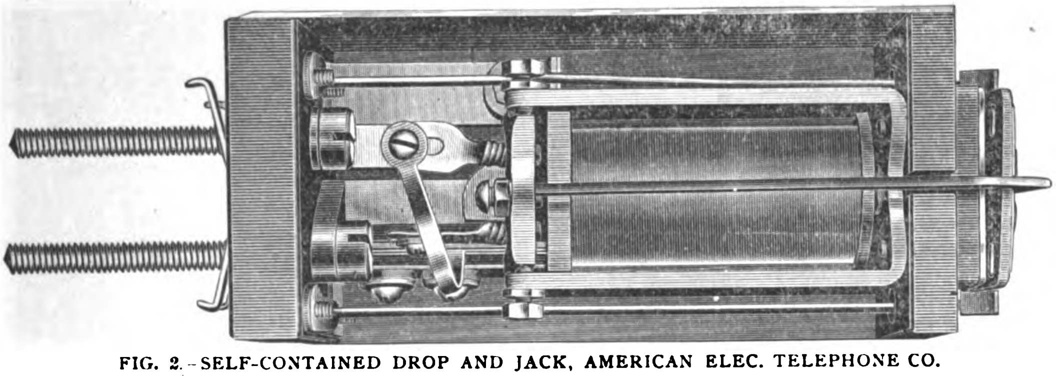

FIG. 2.–SELF-CONTAINED DROP AND JACK, AMERICAN ELEC. TELEPHONE CO.

The operator's set includes a powerful magneto hand generator wound to ring through from 35,000 to 40,000 ohms resistance and having heavy quantity output, thus being adapted for ringing of series bells on short lines and those of high resistance,

and the ringing of a maximum number of bridging bells on long bridged lines; a long distance solid back amplifying transmitter suspended from a neat arm and adjustable as to height and distance from face of board; a long distance type silk wound induction coil with hard rubber heads, screw and washer terminals and soldered connections; a compound telephone watchcase receiver; a special nickeled spring operator's headband, cords, terminal plug and metallic jack.

The cut shows the American Telephone and Electric Company's "Express" switchboard combined. The drop and jack can be removed from and replaced in switchboard within a few seconds' time without disturbing the line, generator or night alarm circuits.

Express switchboards are furnished adapted for use in exchanges of any size up to several thousand lines. The company has filled orders within the past few months for boards aggregating upwards of 10,000 drops. The business of the company is rapidly increasing due to the excellence of their products, and the energetic efforts of Mr. H. C. Dodge, the general manager of the company, to whom we are indebted for the above data.

New Apparatus of the Western Telephone Construction Co.

THE accompanying cuts represent some of the new types of apparatus manufactured by the Western Telephone Construction Co., of Chicago. They certainly deserve more than

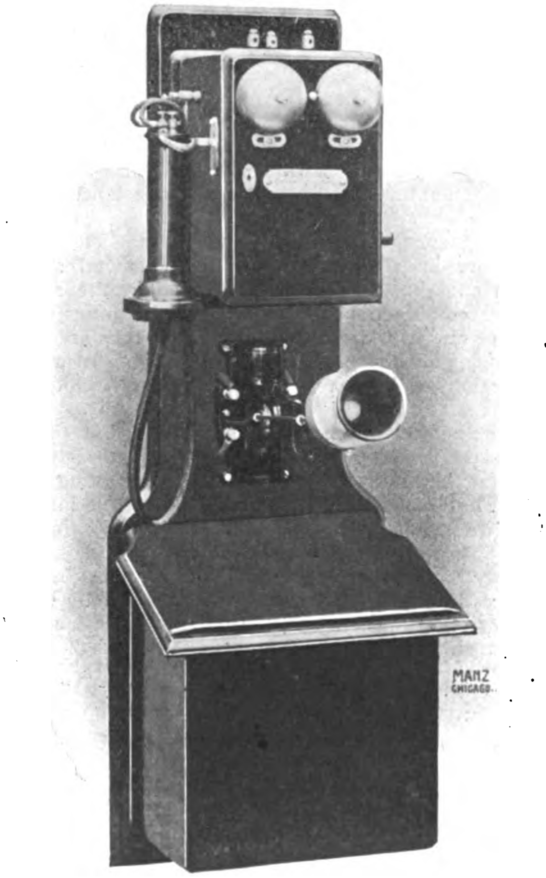

FIG. 1.—ROCKER ARM WALL SET, WESTERN TELEPHONE CONSTRUCTION CO.

passing notice for their artistic design and handsome finish, to say nothing of their good mechanical and electrical qualities.

Fig. 1 represents their rocker arm wall set which embodies all of the latest improvements known to this type of instrument. The powerful granular carbon transmitter of this company is mounted upon an iron rocker arm, handsomely enameled and decorated in gilt. In the base of this arm is placed their new long core, all silk induction coil, specially designed to give best results with this particular transmitter. The receiver is of their well known bipolar type, and all of the contact points of the hook switch are of platinum. These instruments are furnished in oak, cherry or walnut.

Figs. 2 and 3 represent their new cabinet desk sets, which for general elegance would be hard to surpass. They are furnished in either oak or cherry, and upon special order in mahogany or any other wood desired. Four different designs are

FIG. 2.—CABINET DESK SET; WESTERN TELEPHONE CONSTRUCTION CO.

being turned out by this company, of which but two are illustrated here.

In Fig. 3 the generator, hook switch, ringer and induction coil are all in plain view, being seen through the beveled glass panel in the front of the cabinet. All of the metal parts of these pieces of apparatus are highly nickel plated and polished.

In Fig 2 the working parts of the instrument are concealed, and a beveled edge mirror is mounted upon the backboard.

FIG. 3.—CABINET DESK SET, WESTERN TELEPHONE CONSTRUCTION CO.

By mounting the transmitter arms at the extreme left hand side of the top board of the cabinet, the desk room is not inter-

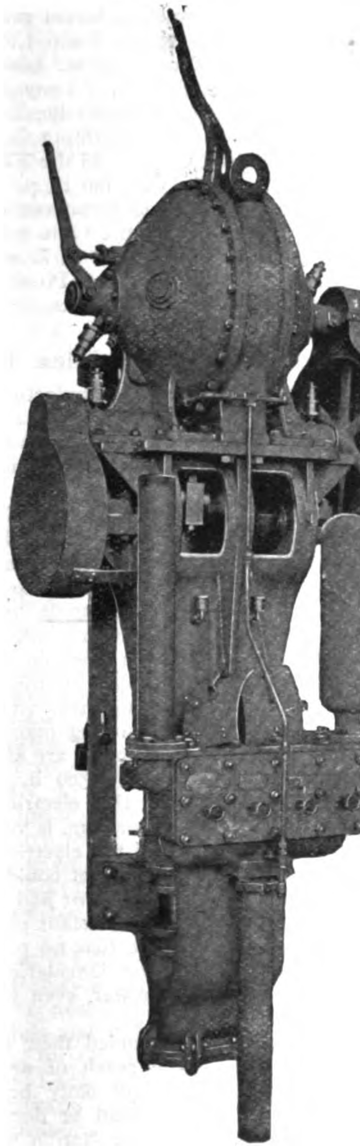
fered with, thus adding greatly to the convenience of the instrument.

The Western Telephone Construction Company reports a very gratifying sale of these types of apparatus.

G. E. Mine Sinking Pump at Pachuca, Mexico.

A MINE SINKING PUMP, compact in form, of full rated capacity and efficiency and not easily damaged by moisture or hard usage has recently been constructed by the General Electric Company. The pump is of the duplex double acting type with outside packed plungers. Its cylinders are 5 x 6 inches; it runs at 75 revolutions per minute and has a capacity of 150 gallons against 300 feet head. It is driven by a specially designed 15 h. p. enclosed induction motor in which the gears and all the mechanism are completely protected by a water-tight steel casing.

The shaft and starting lever pass through stuffing boxes. The



G. E. MINE SINKING PUMP.

casing was tested for leakage with steam pressure up to 35 pounds per square inch. The wearing parts are all large and of extra heavy design, the crank shafting being one solid forging fitted with brass bearings. The connecting rods are of the marine end type and are forged. The guides are bored in the intermediate mechanism so that the cross head must always be in line with the pump cylinders. By removing one plate on the pump, all the valves may be reached at one time.

This sinking pump was designed to withstand without injury all the hard usage to which mining machinery is subjected. As the case is water tight, the pump works as well under water as out. It may be completely "drowned" by a sudden inrush of water in the mine but its operation is not affected. This pump is now in operation at Pachuca, Mexico.

Telephone Box Hardware.

Hammacher, Schlemmer & Company, of 209 Bowery, New York, call attention in our advertising columns to one of their many lines, viz., telephone box hardware.

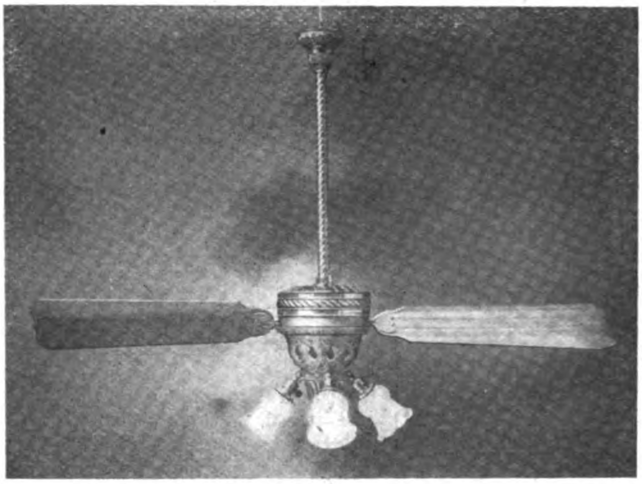
Their extensive connections in the cabinet hardware line give

TELEPHONE BOX HARDWARE.

them exceptional facilities for supplying goods of this character. In addition to this class of hardware they handle a large line of factory supplies, wood working and metal working tools, spring wire, belting, emery wheels, etc. Their 400 page catalogue of tools is a perfect encyclopedia of the line.

Hunter Direct Current Fans.

OUR illustration shows a very handsome ceiling fan manufactured by the Hunter Fan and Motor Company, Fulton, N. Y. The motor, which is enclosed in an artistic casing, is of the direct current type. It has a toothed armature, powerful soft-steel fields, and a short magnetic circuit. The two bearings, which are submerged in oil, are spread far apart so as to prevent the armature from rubbing against the poles, as is



HUNTER FAN MOTOR FOR 1898.

often the case with a short single bearing, after it gets worn a little. The motor consumes very little current, using less than one ampere at a speed of 192 revolutions per minute; and has a five foot sweep of the blades. The speed can be varied by a two-speed switch on the bottom of the fan. The company manufacture direct and alternating current electric and belt-driven ventilating fans of every description.

Roebling's Climax Resistance Wire.

John A. Roebling's Sons Company have just issued a small pamphlet setting forth the properties of their new "Climax" resistance wire.

This wire has a high specific resistance, and possesses strength and toughness far in excess of the ordinary wires used for resistance work. It has nearly fifty times the resistance of copper, while German silver has only eighteen times, and ordinary steel wire about eight times the resistance of a copper wire of the same diameter.

The resistance of this wire varies slightly. One piece may

show fifty times the resistance of copper, while another will show only forty-eight times copper resistance. Its low temperature coefficient fits it for any use to which German silver can be applied and its high specific resistance renders it an economical substitute for ordinary steel wire for resistance work. Its mechanical properties render it available for rheostat work where German silver is utterly useless, on account of its brittleness caused by repeated heating and cooling.

The pamphlet contains tables of resistance and carrying capacity of this new resistance wire, which possesses the remarkable properties referred to above.

Swinging Tree Insulators.

The swinging tree insulator which is manufactured by the Western Electric Company is a device which will be thoroughly appreciated by the central station manager whose lines pass through trees. This insulator fully protects the lines from swaying branches without cutting the insulation and is readily hung by a wire twisted through the hole at the top. This loop of wire can be lengthened and adapted to a wide range of conditions. A good time of the year to inspect line wire is just before the trees begin to bud and blossom, for at that time it can easily be seen how near the wires approach the limbs and there are better opportunities for placing the tree insulator in an advantageous position when the view is thus unobstructed. These insulators can also be used to support arc light wires when passing under bridges, awnings, or iron roofs.

The Electric Storage Battery Co.

A new catalogue has just been issued by the above company setting forth the many advantages claimed for the chloride accumulators for central stations, isolated plants and traction work. The catalogue contains many illustrations of the various types and weights and prices of cells. A chapter on the use of the hydrometer and full instructions for setting up and using the chloride accumulators make the catalogue a handy reference book for anyone in charge of accumulators.

Mr. W. R. Garton.

The above named gentleman has severed his connection with the Central Electric Company and will shortly open an office in Chicago, devoting his entire time and attention to his own personal interests, as well as the representation of Eastern manufacturers. Mr. Garton has been well known in the field for a long time and during the past three and a half years has acted as the manager of the Central Electric Company's Railway Department.

Large Lundell Motor Contract.

The Sprague Electric Company, of New York, have secured the contract for motors to be installed in the new works of the John Stephenson Company, Limited, Elizabethport, N. J. This is a large and important contract and some 48 motors will be utilized, ranging from 3 h. p. to 40 h. p., mostly large size machines. The motors will be of the well known Lundell type and will be direct connected, belted or coupled to the latest types of wood working machinery. As is generally known, the Lundell motors are of the inclosed type and are admirably adapted for use in wood working machinery establishments where, of necessity, the atmosphere is filled with dust. Several large size Lundell direct connected exhaust fan outfits will also be included in the equipment. The plant will be one of the largest of its kind in this country and will be equipped exclusively with the Lundell motors.

Metropolitan Electric Construction Co.

This recently formed company has opened offices in the Commercial Cable Building, where its business will be under the care and management of Mr. W. B. McQuesten. It proposes to devote its energies chiefly to the installation of electric elevators and other machinery manufactured by the Sprague Electric Company, which has a strong representation in its control, and of which it is practically a department. It has also a large personal interest in it outside of the Sprague Company, which it is expected will contribute also to efficiency and economy of operation.

Recent Sales by the Ridgway Dynamo and Engine Co.

The Ridgway Dynamo and Engine Company, Ridgway, Pa., have recently made the following shipments: One 90 h. p. tandem compound engine to the Deadwood and Delaware Smelting Company, Deadwood, S. D.; one 125 h. p. simple engine to the Logan Consolidated Coal Company, Mattewan, W. Va.; one tandem compound engine direct connected to one 100 k. w. generator to the United States Iron and Tin Plate Manufacturing Company, Demmler, Pa.; one 200 h. p. simple engine to Newsam Bros., Kingston Mines, Ill.; one 175 h. p. simple engine to the Lackawanna Light, Heat and Power Company, Taylor, Pa.; one 50 k. w. belted generator to the City of Macomb, O. Besides the above shipments, the following contracts have been closed: One 50 h. p. simple engine to the Waterous Engine Works, Company, Ltd., Brantford, Canada; two tandem compound engines direct conected to two 150 k. w. generators to the Bucks County Railway Company, Doylestown, Pa.; one 250 h. p. simple engine and one 150 k. w. belted generator to the Berwind-White Coal Mining Company, Scalp Level, Pa.; one simple engine direct connected to 20 k. w. generator to the Schussler Brewing Company, Buffalo, N. Y.; one 35 h. p. simple engine to the Model Mill Company, Nashville, Tenn.; one 200 h. p. simple engine to the Phillipi Coal Mining Company, Philippi, W. Va.; one 125 h. p. simple engine to the Eldon Coal and Mining Company, Ottumwa, Ill.; one 150 h. p. tandem compound engine to the State of Arizona Improvement Company, Yuma, Ariz.; one 100 h. p. engine to the Ohio and Mississippi Coal Mining Company, Marion, Ill.; one 25 k. w. belted generator, Fessenden Manufacturing Company, Pittsburg, Pa.; one 40 k. w. belted generator, DuBois Iron Works, DuBois, Pa.

Henry R. Worthington's Triplex Pumps.

The triplex electrically driven pump manufactured by Henry R. Worthington, Brooklyn, N. Y., is different in several features from anything heretofore brought out, and marks a decided step towards the development of the theoretically perfect electric pump.

Two of these machines have recently been installed at the new station of the Brooklyn Edison Electric Light and Illuminating Company, for feeding the boilers (see Electrical Engineer, January 6, 1898; page 18). They are driven by specially wound low speed motors, the connection being made by a single reduction of cut spur gears; that is, the spur wheel carried on the pump shaft meshes directly with a rawhide pinion carried on the armature shaft. This does away with the counter shaft and high speed gears ordinarily used, and gives a neater looking, more compact, and practically quiet running machine. The air pumps and circulating pumps at this station are also electrically driven; the boilers are rated at about 2,500 h. p., and carry 165 pounds steam pressure. The fact that electricity should be used for the auxiliaries in preference to steam, is very convincing evidence of the growing popularity of the electric pump. Formerly it was thought that the electric current could only be used to advantage when steam was not available or had to be brought through a long line of pipe from some distant plant, but engineers have since learned by experience that no pumping installation should now be made without first considering the possible advantages of electricity for motive power, even where steam is readily obtainable.

The central stations have now extended their lines so as to put the electric current within the reach of nearly all large factories, and the use of electricity is daily becoming more general, especially for such work as can be done in the daytime. Such uses afford a central lighting station means of leveling the daily load line and obtaining a revenue from the costly generating machinery, which would otherwise at such hours be practically idle. The electrical companies appreciate this fact and are willing to supply electrical current during the daytime at very reduced rates.

NON-POLARIZING DRY BATTERY COMPANY, 625 Broadway, report an excellent demand for their O. K. dry battery. Orders are pouring in from all parts of the country, necessitating the employment of extra help as well as the installing of additional machinery in order to deliver goods promptly. The O. K. dry battery is adapted for all open circuit work and is claimed by the manufacturers to be superior to anything now on the market.

ADVERTISERS' HINTS

THE GENERAL ELECTRIC COMPANY illustrate several types of enclosed arc lamps. Durability, efficiency, artistic ornamentation, attractive proportions and easy manipulation are some of the characteristics claimed for them.

KEYSTONE ELECTRIC COMPANY, Erie, Pa., advertise their type "G" multipolar generators and motors in capacities from 1 to 7 kilowatt slow and medium speeds. They have ironclad armatures, steel poles and field ring, self-oiling bearings and may be bolted to the wall or ceiling.

THE UNITED CORRESPONDENCE SCHOOLS, 154 Fifth avenue, New York, again call attention to their course in electrical, mechanical, steam, civil, and sanitary engineering. It costs something less than seven cents a day to enroll.

H. B. COHO & COMPANY, St. Paul Building, New York, have added "Van" gas engines, "American" rheostats and "Translucent" fabric to their list of well known specialties.

J. P. WILLIAMS, 39-41 Cortlandt street, New York, advertises "Paragon" power motors of 1-12 and 1/8 horse-power, wound for storage batteries, and also a full line of latest type ceiling desk and wall fans.

THE DIAMOND ELECTRIC COMPANY, 1202 Fisher Building, Chicago, Ill., advertise the Scheeffer wattmeters and transformers and mention some of their respective points of merit.

THE AMERICAN STOKER COMPANY, Garfield Building, Brooklyn, N. Y., state the guarantee, a very broad one, under which they sell their automatic stokers.

THE AMERICAN ELECTRICAL HEATER COMPANY, 197 River street, Detroit, Mich., show another variety of their apparatus.

THE GOLD STREET CAR HEATING COMPANY, Frankfort and Cliff streets, New York, say their heaters combine the highest efficiency with the greatest economy and are the acme of simplicity.

THE McCAY-HOWARD ENGINEERING COMPANY, 106 East German street, Baltimore, Md., are advertising the Ries regulating socket as a means of saving current and lamps.

THE RUSHMORE DYNAMO WORKS, Jersey City, N. J., cite the advantages of their new multi-voltage system as applied to any multipolar machine. This system is in operation at the company's factory and inspection is invited.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., are headquarters for all iron goods used in electrical line construction, such as lag-screws, pole-steps, cross-arm braces, etc. These are all carried in Chicago stock and prompt shipments may be made at any time.

WHITMAN & COUCH, 196 Summer street, Boston, say that as "the proof of the pudding is in the eating" it is a first-rate plan to try their telephone apparatus and place your exchange on a paying basis.

FRED. J. CROSS, 310 Mooney-Bristane Building, Buffalo, N. Y., may be consulted on all matters pertaining to electrical engineering.

KIELEY & MUELLER, 7-17 West Thirteenth street, New York, manufacture a great number of steam specialties, among which may be noted steam traps, pressure and damper regulators, noiseless and tight back pressure and relief valves especially adapted for electric and high pressure plants.

THE UNITED ELECTRIC IMPROVEMENT COMPANY, Alleghany avenue and Nineteenth street, Philadelphia, offer their incandescent lamps in competition with any others on the market.

THE MICHIGAN PIPE COMPANY, Bay City, Mich., are ready with a new catalogue descriptive of their creosoted wood conduits for underground wires. They are said to be practically indestructible.

THE MONTAUK MULTIPHASE CABLE COMPANY, 100 Broadway, New York, say of their cable: "It is as reliable as a galvanometer, as infallible in action, and is continuously thermostatic." Their descriptive matter may be had on application.

THE DETROIT SWITCHBOARD AND TELEPHONE CONSTRUCTION COMPANY, Majestic Building, Detroit, Mich., manufacture telephone apparatus of all kinds and contract for and build telephone plants and toll lines. They submit a list of plants they have installed, and illustrate a switchboard and some types of instruments.

THE CROUSE-HINDS ELECTRIC COMPANY, Syracuse, N. Y., furnish switches, switchboards, panel-boards and electrical specialties. They reproduce their voltmeter switch. Their catalogue for the asking.

THE WESTINGHOUSE ELECTRIC & MFG. COMPANY, Pittsburg, Pa., state their reasons for advertising.

THE LECLANCHE BATTERY COMPANY, 111 East 131st street, New York, advertise the "Gonda" battery as the standard open circuit battery of the world.

THE WESTERN TELEPHONE CONSTRUCTION COMPANY, Chicago, Ill., advocate the purchase of telephones that not only talk well but look well also. They invite requests for photos and prices.

L. A. CHASE & COMPANY, Boston, Mass., publish a testimonial from the Salem Electric Lighting Company commendatory of the Elden alternating circuit breaker.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., recommend their system of mechanical draft as the most economical and satisfactory in the production of steam.

JOHN A. ROEBLING'S SONS COMPANY, Trenton, N. J., advertise the "Columbia" rail bond, which has a contact equal to seven times the section of the rail.

THE NATIONAL CARBON COMPANY, 620 Highland avenue, Cleveland, Ohio, manufacture a complete line of battery cells and specialties besides the carbons bearing their well known name.

HART & HEGEMAN MFG. COMPANY, Hartford, Conn., call attention to their 10 ampere, double-pole snap switches.

SIPE & SIGLER, Cleveland, Ohio, the successors to the Willard Electric and Battery Company, have completed improvements in their factory to facilitate the rapid and extensive manufacture of the Willard battery. They make a special offer to those desiring to make a scientific test of their cells, the full terms of which may be found in their advertisement.

THE CENTRAL ELECTRIC COMPANY, 173 Adams street, Chicago, having finished their inventory find their stock of supplies and specialties to be very large and complete, and are, therefore, able to fill all orders promptly.

THE AMERICAN ELECTRIC TELEPHONE COMPANY, 173 South Canal street, Chicago, Ill., advertise long distance and exchange telephones equipped with their patented adjustable arm and heavy output nickeled generators. They also advertise pay station signs for independent companies at 80c.

HAMMACHER, SCHLEMMER & COMPANY, 209 Bowery, New York, advertise telephone box hardware and wood and metal working tools.

THE ELECTRICAL EXCHANGE, 166 South Clinton street, Chicago, offer some excellent bargains in dynamos, arc lamps and transformers of standard makes.

WESTERN NOTES

MESSRS. SIPE & SIGLER, manufacturers of the Willard storage battery, have recently filled orders for the Western Union Telegraph Company for 120 "Willard" storage cells for Hoboken, N. J., 40 cells for Scranton, Pa., 30 cells for New Haven, Conn., 25 cells for Newark, N. J., and 343 plates for Ravenna, N. Y.

THE UPTON MIDGET is already a very popular specialty. The small size, light weight and tasty appearance of this long burning arc lamp makes it a very desirable arc lamp for inside work, while its positive and steady action and general reliability make it a popular lamp for all places where long burning is required. The Electric Appliance Company, Chicago, will be glad to send their latest circular on this specialty on application.

THE BRUNT REGULATING SOCKET for regulating the candle power of incandescent lamps, now being introduced by the Central Electric Company, is meeting with a very ready sale. These goods have forced their way to the front as the best articles of the kind yet produced for regulating the candle power of incandescent lamps.

CHICAGO.—The General Electric Company is building 36 additional 175 h. p. motors for the Metropolitan West Side Electric Elevated Road.

NEW CIRCULAR OF THE WALKER COMPANY.—The Walker Company, of Cleveland, Ohio, and New Haven, Conn., have just issued circular No. 1,063, which contains a very exhaustive treatise by Prof. S. H. Short on "Electricity as a Motive Power on Elevated Railways." The article is profusely illustrated and contains many valuable curves and tables, such as the comparative cost of steel and copper feeders and data of actual tests of train performances on elevated roads

CALENDAR OF THE WAGNER ELECTRIC MANUFACTURING COMPANY.—The Wagner Electric Manufacturing Company, St. Louis, have issued a very handsome calendar which illustrates in the words of the company "A few things we make." Among these should be mentioned the d. c. generators, transformers, a. c. motors, fans, switches, switchboards, instruments and d. c. motors.

NEW YORK NOTES.

THE MONTAUK THERMOSTATIC CABLE.—The interest manifested in the new thermostatic cable of the Montauk Multipolar Cable Company, 100 Broadway, New York, is shown by the large number of inquiries received by that company from all parts of the country. Samples have been requested from all branches of the electrical trade, such as telephone and telegraph companies, supply houses, contractors, fire alarm companies, central stations, and electrical works in general. This company are mailing sample cards of their new cables to any address upon application.

PELTON WATER WHEEL COMPANY.—The Pelton Water Wheel Company report a large run of business for the last two months of 1897. Among the more important shipments may be mentioned: Wheels, governors and accessories covering a 2,000 h. p. plant for San Rafael Paper Mills, Mexico; six wheels for various other localities in Mexico; a 1,200 h. p. wheel with accessories for an electric transmission plant for Petropolis, Brazil, this being a duplicate of their former plant; an electric power transmission plant for Prujillo, Brazil; seven wheels with governors, pipe lines and accessories to operate tea and coffee plantations in Java; three wheels for the Ruby Mines in India; two 600 h. p. wheels for operating mills in Tasmania, Australia; three 1,000 h. p. wheels with governors and accessories, direct connected to Stanley generators, for the Yuba Power Company, Marysville, Cal.; one 200 h. p. wheel for operating the mill of the Dexter Gold Mining Company, Tuscarora, Nevada; nine wheels for various mining operations in California. A large number of orders are in hand, making the outlook for the present year very encouraging.

AFFIDAVITS OF THE FRANKLIN H. KALBFLEISCH COMPANY.—In reply to a statement made by a competitor that "No acid manufacturers are now making sulphuric acid or oil of vitriol from Sicily brimstone," the Franklin H. Kalbfleisch Company, New York, have published a number of affidavits, each one sworn to by officials before a notary public, from which the following extract is taken: "Every pound of sulphuric acid or oil of vitriol manufactured by the aforesaid factory in Brooklyn, N. Y., is made strictly from Sicily brimstone;" a similar statement regarding the output of the Waterbury, Conn., factory, and others of a similar nature.

DeVEAU & COMPANY, the well known manufacturers of telephones, electrical supplies, etc., are leaving their old quarters on Frankfort street, and after February 1 will have their office and factory at 27 Rose street, where they will enjoy increased facilities for the large and growing trade which they have built up.

MR. W. S. TURNER, M. S., consulting and constructing electrical and mechanical engineer, has removed his office from No. 1 Nassau street to 120 Liberty street, room 1,000. Mr. Turner has had a large and varied experience in consultations, specifications, plans, estimates, tests, reports, supervision and purchasing in connection with electric traction, electric lighting, power transmission and steam engineering. He has been connected during the past ten years with the Westinghouse Electric Light Company, Edison Electric Light Company, and the Woodbridge & Turner Engineering Company. Mr. Turner is a member of the A. I. E. E. and a graduate of Cornell University.

THE GENERAL ELECTRIC COMPANY have just issued a very handsome calendar which embodies the commendable feature of a moonlight schedule, arranged for New York State, giving for each day in the year the hours for lighting and extinguishing the lamps. The hours for lighting are marked in red and for extinguishing in black, and when no lamps are required, the space is marked "No Light." A calendar embodying such useful functions is always welcomed by the station engineer and superintendent.

HON. GARDINER C. SIMS, of the Vulcan Foundry, Providence, R. I., was a visitor to New York City last week, attending the meeting of the National Foundrymen's Association. He also attended the meeting of the American Institute of Electrical Engineers.

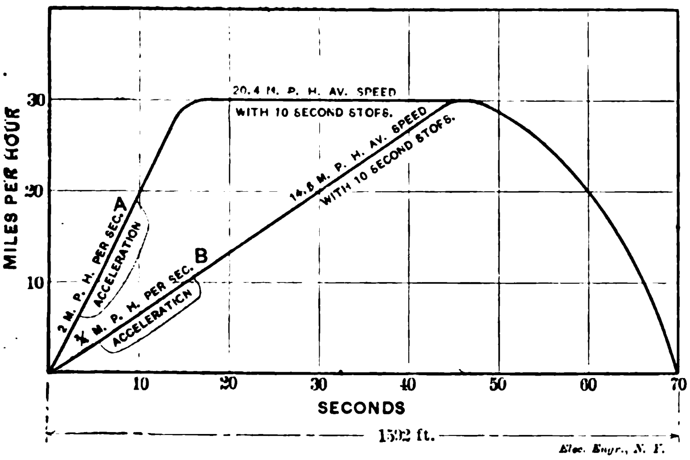
ELECTRIC TRANSPORTATION

Some Notes on Electric Car Acceleration.

BY J. R. CRAVATH.

IN consideration of the recent interest that has been aroused in the possibilities of very rapid train acceleration with electric motors it may not be out of place to call attention to the fact that the acceleration used in common daily electric street railway practice is excellent and much more rapid than in any other branch of railroading with the one exception of the cable road.

Thus, for example, a 15,000 pound single truck electric street car, of a type familiar to the writer, having two 25 horse-power motors geared to run 16 to 18 miles an hour maximum speed can be started and brought up to speed on a level in about 12 seconds on a dry or clean track. This is ordinary good practice and represents an acceleration of 1½ to 1⅓ miles per hour per second. This is not so very far below the rate of 2 miles per hour per second acceleration which has been recently proposed and experimented with for elevated and suburban work. As said before, this 1⅓ to 1½ miles per hour per second acceleration may be called common good practice on street railways. I may add also that a great many motormen try to do much better than this, but the results in acceleration are usually not in proportion to the power used owing to a number of causes,—



CAR ACCELERATION CURVES.

but that is another story. Such a 12 second start with the kind of car mentioned can be made with a maximum current when the motors are thrown in multiple of 60 to 70 amperes and does not abuse the ordinary 25 horse-power railway motors used now on such cars. There are frequently days, however, during the winter season in our large cities when mud and snow make it difficult to accelerate as quickly as this, because of a slippery track.

On steam and elevated roads the rails are always clean except during sleet storms and the proposed rate of 2 miles per hour per second is no doubt feasible if the current is applied to the motors without jerk and the greater part of the weight of the car is put on the driving wheels.

Whether such a rapid acceleration will be worth all that it will cost to get it is the great problem to be decided to-day by those considering the equipment of elevated and steam suburban lines with electricity. That the outlay will be far beyond anything heretofore known in the electric railroad field all will admit, but it is also evident that such an acceleration when carried up to speeds of 30 to 50 miles an hour will give a rapid transit schedule which will leave far behind any present schedules. It lies with the engineer to properly calculate the outlay, and with the directors and stockholders to judge whether the increased receipts are likely to justify the expenditure. Few realize what an enormous investment a system providing for such a rapid acceleration would involve. I will not attempt to analyze in a few sentences problems that should properly take weeks of calculation, but some idea can be had of the magnitude of the proposition when it is seen that the rate of acceleration proposed (to 30 miles per hour in 15 seconds) is about three times the common practice on the elevated roads of Chicago. As the heating of the motors is according to C^2R, the amount of heat generated during acceleration in the motors of a road operating with the fast acceleration proposed would be three times that generated in the motors used on the two West Side electric elevated roads in Chicago. Experience has demonstrated the advisability of heavier equipment on those lines, however, and it would not, therefore, be safe to count on less than four to five times the motor capacity now employed on the motor cars of those roads if they were to be changed so as to permit the proposed rapid acceleration with the same maximum speed as before. This is one important item. It is partly offset by the fact that the faster acceleration, and, consequently, faster schedule would reduce the number of trains necessary to perform a given service. The power required during acceleration of each train being increased 300 per cent. it would not be safe to count on a power plant capacity less than double that at present used, and a still greater increase of feeder lines, although the average load would be light. Furthermore, such acceleration necessitates the use either of the Sprague multiple unit system or a heavy motor car pulling only one trailer. The latter plan will not take care of rush hour traffic without interference of trains. The Sprague system is admitted to be of low electrical and mechanical efficiency, and is, therefore, not only costly to operate on the basis of kilowatt hours per car mile, but, furthermore, means a heavy investment for the motors, air pumps and controlling devices necessary on every car. The electrical repair and inspection department must also be increased several hundred per cent. with this system to take care of the numerous motors and other appliances. This is not said to discredit the Sprague system, but simply to point out another large item of expense that must be figured in on the rapid acceleration scheme.

The question then to decide is whether all this extra investment and extra operating expense is likely to be justified by the results in passenger traffic.

On this I will not pretend to say. The accompanying curves have been plotted diagrammatically to determine what effect on the schedule an acceleration to 30 miles per hour in 15 seconds would have on a road where the practice is now to accelerate to 30 miles per hour in 45 seconds. Curve A shows the rapid acceleration and gives an average speed with 10 second stops and stations 1,592 feet apart of 20.4 miles per hour. Curve B shows the slower acceleration and gives an average speed of 14.6 miles per hour, the stops and braking curves being the same in both cases. This is certainly a difference it is worth paying something to get, as it amounts to about 25 per cent. in running time, and that will attract a good many passengers.

There are many other phases of the question that I will not take space to consider here. The engineer of any rapid transit line now considering the adoption of electricity has many complicated problems to solve.

Apparatus For the London Underground.

The General Electric Company has received orders from the British Thomson-Houston Company, Limited, covering the complete locomotives for the Central London Underground Railway. The original contract between the two latter companies included, with the special gearless motors and other electrical equipment, 32 locomotives for this important underground system, but, these, it was supposed, would have been built in England. The decision to confide the construction of the locomotive cabs and trucks, as well as the electrical equipment, to the General Electric Company is dictated by the desire to have the locomotives built complete under the same supervision.

The locomotives will each weigh about 45 tons, and will be

equipped with a total of 800 h. p. in motors. The trains to be hauled will be made up of five cars, giving a total load of 150 tons, 10 tons heavier than the ordinary Manhattan Elevated train. The schedule speed will be 15 miles an hour.

The diameter of the tunnel being 11 feet 6 inches only, motor cars could not be used. The entire electrical equipment will, therefore, be placed on locomotives which will probably resemble in appearance those in use on the Manufacturers' Railroad in New Haven, Conn., and on the Hoboken Shore Road, Hoboken, N. J.

Municipal Ownership of Street Railways in Massachusetts.

A Report Against it by a Special Investigation Committee.

UNDER an act of the last State Legislature a committee consisting of Charles Francis Adams, chairman, and ex-Congressman William W. Crapo, of New Bedford, and ex-Mayor Elihu B. Hayes, of Lynn, has been investigating the relation of street railways to municipalities. Mr. Adams, who wrote the report, subject to approval, went to Europe, and the others visited about twenty cities in the United States and Canada. Some of the evidence taken appeared at the time in the columns of The Electrical Engineer. They now report against the municipal operation of street railways, but are also of opinion that municipal ownership of tracks, with operation by a corporation is preferable to the present system of private ownership and operation which prevails for the most part of the United States. They were also instructed to consider the taxation of street railways. Their conclusions are embodied in two bills. One provides for municipal ownership of tracks. The other changes the system of taxation. Whenever a street railway company has paid 8 per cent. or over for the year, it must pay into the State treasury, in addition to its franchise tax, as much as it has paid over 8 per cent. This tax is to be distributed to the cities and towns according to the trackage within their limits, instead of according to the residence of stockholders, as is now done. Local taxation is to be a proportion of the gross receipts by a sliding scale according to receipts per mile of track operated by the company in the city or town compared with the total length, as follows:

In case of companies whose annual gross receipts per mile of track operated are $7,000 or less, 2 per cent. of the total annual gross receipts; in case of companies whose annual gross receipts per mile of track operated are more than $7,000 and less than $14,000, 2¼ per cent. of the total annual gross receipts; in case of companies whose annual gross receipts per mile of track operated are more than $14,000 and less than $21,000, 2½ per cent. of the total annual gross receipts; in case of companies whose annual gross receipts per mile of track operated are more than $21,000 and less than $28,000, 2¾ per cent. of the total annual gross receipts; and in case of companies whose annual gross receipts per mile of track operated are $28,000 or more, 3 per cent. of the total annual gross receipts. The tax provided by this section shall be in addition to the taxes now provided by law.

One provision is that all amounts paid to cities and towns under the provisions of the act shall be treated as a separate fund, and shall be applied to the construction, repair, and maintenance of the public ways within such cities and towns.

The report shows how the idea of regulation by means of private competition, as in the case of railroads, was followed for a long time, but the times have changed. "The modern practice, as well as theory, is the consolidation of lines in a given municipality under one ownership, that ownership to be held to strict accountability as a recognized public agency." Economy of management will result. "Single ownership of some sort, public or private, may therefore be accepted as a condition of the problem." The report discusses the devotion of streets to car traffic. There are three distinct lines of treatment of the relations between the street railway and the municipality, says the report. The first is the outcome of the original idea of private ownership of both track and vehicle. This complete private ownership exists in both America and Europe. The second line of development recurs to the original principles of ownership, that the street and its pavements are public property, but the vehicles which run upon them belong to private parties, whether individuals or corporations. No distinction is made in the character of the pavements as to material. The municipality concedes to a company the right to run vehicles on a specially prepared part of the pavement, exclusively. In this case the vehicles and motive power only belong to the private company. The third line of development is in the direction of full public ownership—what is known as municipalization.

The report then speaks of the situation in different places in Europe. Private ownership is most common in America. The second system is most common in Germany. In Great Britain there is a strong tendency towards municipalization. Of the system in Massachusetts it is said: "As a working machinery for the daily accommodation of vast numbers of persons, the street railways of the commonwealth fulfil their function quite as well, with as little friction and at as reasonable a cost, as any other similar machinery elsewhere which the committee has had an opportunity to study." The committee ridicule the foolish yarns of municipal advocates of the wonderful working of other systems in foreign cities. They could not find such results from their investigations.

The committee say that the street railways of Massachusetts have cost much more than they could be replaced for, and that it is more than probable that there have been instances of over-capitalization through questionable processes of financiering, but these incidents are inseparable from an unusually rapid development along new lines. The fundamental question is not merely one of greater or less expenditure; but what would have been lost if the expenditure had not been incurred must also be considered. Statistics concerning Boston, Glasgow, and Leeds show that Boston street railways carry many more people according to the population. Massachusetts is far in advance of any portion of Europe in distributing urban population over a wide area. This has been brought about in an extraordinarily short time, not by "drastic, radical legislation," but by the energetic expansion of the railway system. It remains to be proved that the costly experimenting has not been worth what it cost.

A more fixed tenure of franchise was one of the two points for the committee to consider. The report says on this point:

The substitution for the present indefinite concessions of a specific and binding contract, covering a fixed term of years, setting forth the rights and obligations of the parties thereto, and containing a rule of compensation for the purchase of the property in case of failure to renew, at once suggests itself as a measure to reform; and yet it was very noticeable that, in the course of the protracted hearings before the committee, no such change was advocated by the representatives of the municipalities or of the companies, nor, apparently, did the suggestion of such a change commend itself to either. Some amendments in detail of the existing law, and partial measures of protection against possible orders of sudden, ill-considered, or aggressive revocation, were suggested; but it was evident that, while the municipalities wanted to retain as a weapon the right of revocation at will, the companies preferred, on the whole, a franchise practically permanent, though never absolutely certain, to a fixed contract tenure for a shorter term, subject to the danger of alteration at every periodic renewal.

The committee question the wisdom of disturbing methods which work well in practice, even if they are illogical. Furthermore, in Europe the fixed period operates as a serious check on enterprise. Strong inducement exists to get the largest profit possible out of the time conceded without increasing the value of the system, which must again be subject to negotiation for another fixed contract. In the American cities visited by the committee the matter of a franchise has been productive of dissension, poor service, scandals, and unhealthy political action. "In fairness, the committee found itself forced to conclude that the Massachusetts franchise, which might perhaps not improperly be termed a tenure during good behavior, was, in its practical results, best."

The report takes up the complaint, on one hand, in behalf of the public, that too great privileges with too few responsibilities have been given to the railway corporations; and, on the other, the complaint of the corporations that they are insufficiently protected against the public. They conclude that the matter is one of local concern, in the main. The municipalities must judge of the use which they will permit to be made of their thoroughfares; the corporations must judge whether they will accept the grants of location with the degree of protection which is afforded. It is not for the commonwealth to prescribe the terms on either side. Recommendations on the matter are these:

On the one hand, they (the committee) would grant the local

authorities explicit power hereafter to impose such terms and conditions as they deem the public interests demand, on original grants and locations in the localities over which they have jurisdiction; while, on the other hand, they would protect companies whose tracks have been already located from new and perhaps unreasonable conditions sought to be imposed in grants of alterations and extensions, which may be called for, not less for public convenience than by corporate interests.

Taking up next the question of street railway development through regulated private ownership, the report says:

The chief objection to it is obvious—it necessarily involves a divided control of streets, resulting in continual jealousies, misapprehensions and disputes. While, because of its apparent simplicity, as well as from the analogy of the steam railroad, it naturally suggested itself in the early and experimental stage of street railway development, it certainly does not now commend itself as a permanent or scientific arrangement. Even should it be continued indefinitely, the committee is clearly of opinion that it would be conducive to a better state of affairs were the municipalities to assume full control of the streets, meeting all charges for paving and for street cleaning, and receiving therefor from the companies a net annual money payment in lieu of work in kind.

The committee prefer, instead of private ownership, a system known somewhat in Great Britain, but better known in Germany—"a system under which the municipality both owns and controls the whole surface of its streets, whether paved with other material or with iron, and leases to a private company the right to run vehicles over prescribed routes on tracks therein specially provided."

The third line of railway development—municipalization—is then considered. It is said to be yet in the experimental stage. The tendency towards it in Great Britain is pronounced, and it is in practical operation in Glasgow, Leeds and many other places. "So far as development, activity and material and scientific appliances and equipment are concerned, apart from permanent way and track surface, the American street railway is so far in advance of any to be found in Great Britain as not to admit of a comparison. . . . America has experimented at immense cost. . . . while Europe has patiently waited, and is to-day rapidly and quietly appropriating the results for which we have paid." The report, as might have been expected, denies that European experiments have been demonstrated to be successful, and says:

So far from being a demonstrated success, it may, on the contrary, be confidently asserted that nowhere, as yet, has the experiment of municipalization of street railways been worked out to any logical and ultimate results whatever, nor can it be so worked out for at least a score of years to come. Even then, political habits, social traditions, and material and economical conditions vary so greatly and enter to so large an extent into the problem, that it will not be safe to infer that what may have proved safe and practicable in one community is either practicable or safe in another. At the present time the municipalization of the street railways is not accepted as by any means indisputably desirable in Great Britain, while in Germany it is regarded unfavorably.

Municipal Power Over Franchises in Illinois.

Street railway interests of Illinois, which met at Chicago on January 5 as a State association, have prepared a bill for submission to the Legislature designed to make the life of every street railway franchise in the State ninety-nine years. The bill was prepared by C. L. Bonney, of the Chicago General Electric Railway Company, who takes the ground that the street railway companies, being incorporated under the constitution and statutes of the State, the Legislature can extend the franchises. As the Federal constitution recognizes only States and counties, a municipality, he claims, has nothing to do with the granting or extending of the franchise, the municipality having only the power of enforcing police regulations as to the running of cars through the streets. Mr. Bonney also urges that coming legislation be so framed that an appeal from the State Supreme Court to the Supreme Court of the United States will be inevitable. It is reported that immediately upon the conclusion of the present special session of the Legislature, Governor Tanner will be asked to call another to take up street railway affairs.

MUNICIPAL AFFAIRS

Public Control, Ownership or Operation of Municipal Franchises?—VI.

With Special References to Electric Lighting.*

By R. R. BOWKER.

(Vice-President and General Manager New York Edison Co.)

IN 100 American cities of 30,000 population and over recorded by the National Electric Light Association, five have municipal plants; and of 450 smaller cities, fifty-three have municipal plants; or a total of 493 cities with private and fifty-eight with municipal plants. The figures of price for street lighting for the standard arc lamp range from $64.75 in Dubuque, on moonlight schedule, and $68.52 costs (direct expenses only), all night, in Detroit's municipal plant, to a price of $156.95 in Fall River, Mass. The New York report shows prices to be $146, $164.25 and $182.50, nominally for 1,200 candle power lamps; in fact, the first are the standard arc lamps registered elsewhere as 2,000 candle power, the second are the same lamps under exceptional circumstances, and the third are pairs of lamps, not single lamps, supplied from the Edison system. The standard arc lamp using 450 watts in the arc (ten amperes supplied at forty-five to fifty volts) is usually called a 2,000 candle power lamp, but this in New York is rated officially as "at least 1,000 candle power" and is entered in the National Electric Light Association reports as 1,200 candle power, though in other cities counted 2,000, while the lowest standard lamp of 300 watts 6.8 to 7 amperes at forty-five to fifty volts), in use in Brooklyn and elsewhere, is counted as 1,200 candle power.

DATA OF COMPARISON.

The facts as to municipal industries in the chief cities and from the several countries show such range and diversity in method and results that conclusive generalizations are not easy. Each advocate can indeed find individual facts in defense of his own views. It is the usual device of socialist writers to emphasize the ills of an existing system, and to assume that in their new Utopia all would go well. This has been true of much of the argument for the municipalization of industries. The wiser course is perhaps to build from existing conditions, by eliminating the bad features and promoting the good features of an existing system, unless the evidence is conclusive that another system would be in all or in most respects better. In this belief I shall state my own conclusions from these data, and from my personal experience.

It is, of course, not more practicable to reconstruct existing systems altogether on these lines, than it is to remake altogether an existing city in the light of present knowledge and modern methods. Yet Paris and other continental cities have been largely reshaped within this generation, and the trend of progress will be, I think, in the directions indicated. Nor would municipalization be possible with justice, except in view of existing conditions and investments. It is not just, for instance, that a municipality should take over private industries by right of eminent domain or legislative enactment, at the appraisement value merely of the existing plant. The electric lighting industry for example, though not yet 20 years old, has shown extraordinary development and changes, and a large part of its actual cost has been in patent rights, engineering expenses and replacements of machinery or distributing plant. Mr. Edison's original two-wire underground system in New York has been entirely replaced by his improved three-wire system. To write off such replacements is not always practicable in industries which have not reached the paying point. Expenditures on this account are legitimately a part of the actual investment, and they must be taken into account if municipalization is not to mean confiscation. It should be repeated that a fair comparison between a private company and a municipal industry

*This paper is written from the point of view of the economist and citizen, but with the data and experience gained as the executive of the New York Edison Company. To my mind, this should not involve opposition of interests; as he most serves his party who best serves his country, so he most serves the interest of a public-service company who best serves the public. I mention the relationship, however, to forewarn readers of any unintentional bias. It is difficult for any outside the business cited, in an academic discussion, to obtain real bases of comparison.—Reprinted by permission from Municipal Affairs, the Reform Club Quarterly.

requires that the private company shall have, as in Berlin, the advantages usually associated with a municipalized industry.

THE PREFERABLE SYSTEM.

The modern city, it seems to me, should own and control its streets, including, as far as possible, both sub-soil and surface facilities of distribution; should itself provide sewerage and water supply, but should leave to private companies the operation of industries which involve manufacture or complex administration. The city should receive adequate rent for the use of its street facilities, should obtain for the people the social increment by limitations of profit or price, and should give to the private companies every economic advantage of tenure, centralization, etc., possible to a municipalized industry. Charters should be granted for a specific period say of 25 years, with renewals at the option of the municipality upon similar terms, so that satisfactory service would insure a continuing franchise. With the proviso, as in the New York ferry leases, that the new lessee might take over the operating plant at an appraised valuation, this would invite and safeguard the investment of private capital without undue risk. Provision should be made, as in Paris, to secure for the public the most modern improvements and consequent reductions in cost. The city should have its own services, as street lighting, at cost, this including, of course, investment as well as operating charges. With such safeguards, one gas company and one electric light company, competing with each other, and one surface railway company affording facilities for transfer and competing with an underground or elevated system, would give the best economic results. Parallel grants should be made only on the certificate of an authority like the Massachusetts Gas Commission or the New York Railway Commission that they would be for the public benefit. If the grant is not exclusive for the whole city, it should be limited to specified sections.

The city should provide under its main thoroughfares an accessible subway tunnel, as a modern building has in its cellar space for its working apparatus. This sub-street, such as London now has and Stockholm has planned, should give easy access by manholes to the sewers, and should provide space for water mains, gas pipes, electric conductors and other services, both for trunk lines and for local distribution, with access to buildings by side recesses between each two buildings. In other streets a distributing subway system of ducts, preferably on each side to prevent displacement of paving, should be comprehensively planned for water, gas, electricity, etc., with house access at the curb between each two buildings. Rent for these facilities, covering construction interest, maintenance cost and a license for such use of street facilities, should be charged by the city to its own water department, for instance, as well as to the private companies. Where a special system requires private construction, the street license but not the construction interest should be charged. The city might also own and lease the track for a surface railroad as in Toronto, as well as provide a rapid transit tunnel, as is proposed in New York.

An honest and efficient municipal inspection should protect the interests of the citizens. Actual tests should be made from time to time and the results published. Meters should be tested by municipal inspectors on demand of any consumer, as in London, the company paying the charge if the meter is within and the consumer if it is without the legal requirements. Under these conditions the public should get the surest and best service at the lowest price, the few advantages of a municipalized industry with the many advantages of a privately managed industry.

ECONOMIC OBJECTION TO MUNICIPALIZATION.

The first vital economic objection to municipalization is on the score of cost. Economy is closely associated with the progressive management necessitated in private enterprise. A public body does not get its work done as well or as cheaply as a private corporation. The mixture of politics with business is demoralizing to both. Government plants are apt to be "behind the age." The United States government, I have been told, exhibited at Philadelphia in 1876, and again in Chicago in 1893, a cartridge-making machine which private manufacturers had superseded in 1871. The electric lighting plant installed at Manchester in 1893 was three years behind date at that time. The cost of government work is notoriously greater than that of private work. Ships built in the navy yards are known to take longer to build, to cost more and often to be less satisfactory than those built by private contract. In New York the city charges to private companies $8 for the first square yard and $4 for each additional yard for repaving granite block on concrete foundation, and the charge is defended as practically the cost to the city. The same work was done by a private corporation for the city at $2.50 with some profit, and a recent job of which close and complete record was kept cost exactly $2.02½ per square yard. The Court House in New York and the Capitol at Albany are notorious examples of the waste of public moneys in public work too often invited by our political system.

A municipalized industry is at correspondingly serious disadvantage as to management. A modern city government, however highly organized, attempts too much when it attempts everything. While the whole trend of industrial progress is toward consolidation within the same industry, it is toward a differentiation of different industries. A private corporation usually makes contracts for work outside its immediate field, because a specialized organization can do better in any specific work than a general organization. Asphalt paving, for instance, is done for all our cities at best advantage by the Barber and other asphalt companies, which do only this one thing. Contract work in the best private hands safeguards a public employer as no other method can—which is in itself the strongest argument against the municipalization of specialized industries. The Brooklyn Bridge railway, cited as proof that a municipality can operate a railway, was, as unfortunate Brooklynites know to their cost, disastrously managed, and the crush at its terminals was dangerous to life, until a commission of experts trained in the service of private companies devised remedies. The contrast between American and English railways, private corporations, and German railways, state organized, is in point; the Pennsylvania and the New York Central systems are recognized as foremost in the world. The Italian government after "nationalizing" its railways organized two private companies to take over and operate them. In England the private telephone company's "centrals" have taken over nine-tenths of the business, and a consolidation of the government and the private system is probable. In fact, the public service fails to assure the adequate salary and permanence of tenure necessary to retain concentrated and continuous directive ability of the highest order, although the public distinction of office-holding in part offsets the lower salaries in public employment. Many great corporations in New York pay their executive as high or higher salaries than that of the Mayor of New York, even under the new charter, and this high payment for brains is not at the expense of good payment for wages. Successful direction means an increase of business which gives wider employment to more men at better pay.

A municipalized industry, further, is under constant political pressure to pay wages higher than the market rate. The Trades Unions, indeed, favor municipalization largely because they consider that this would involve better wages. On the contrary, nothing could be more demoralizing in the actual labor market, nor more destructive to the legitimate influence of trade organizations. Municipalized industries would not be sufficient, short of entire socialism, to establish the market rate of wages. If municipal industries should pay twenty-five cents a day more than private industries, there would be a rush toward the municipal industries. Men would be induced to pay that, or a part of it, for a place, and would become the easy prey of designing politicians or corrupt superintendents. Such an increase of wages in a force of 1,000 men would mean $75,000 a year, with enormous possibilities of personal corruption and public demoralization beyond anything at present known. It is said that the postal, police and fire services have been kept "out of politics"; as a matter of fact, these classes, largely through their benefit associations, exert an enormous influence at Washington and at Albany, particularly in pressure to raise wages; and in the recent New York election one political "boss" appealed specifically to the interests of these special classes for support. Even under better municipal conditions, as in England, it has been found most difficult to preserve discipline in a municipalized industry, because of the pressure of politicians to reinstate discharged men, as I was personally told in the municipal electric lighting station of a great English city.

FISCAL RELATIONS OF MUNICIPALIZATION.

It has been urged as an objection that private corporations are too often "extortionate monopolies," robbing the people of their right to the social increment. This is in part, and in some

cases, true, but it is an objection that can be met in a better way than by municipalization. It is evident that the trend in the industries cited is toward consolidation, but it is true also that a consolidated company usually reduces prices by virtue of diminished cost for the business motive of increasing consumption and profit.

Municipal Socialism.[1]

BY FRED DE LAND.

THE mayor of Des Moines, a city having a population of 75,000, is the Hon. John MacVicar, who was recently elected president of the League of American Municipalities at the Columbus convention.

For several years the city of Des Moines had paid the sum of $126 yearly for each arc lamp of 2,000 candle power used in street illumination. Soon after his election, Mr. MacVicar started a movement to secure a more favorable contract for the city, and to strengthen his claim for a reduction in rates, secured from various sources official data regarding prices paid by other cities for street illumination, and what the actual cost is where municipalities own and operate the lighting plant.

As there are three local lighting plants in Des Moines, several conferences were then held with a view to the city purchasing one of the three; but a prohibitory price having been placed on the property, negotiations ended and the mayor began to look elsewhere. Then the engineering firm of McCaskey & Holcomb made a proposition to build, within six months from date the contract was signed, an acceptable modern lighting plant for a sum representing about two-thirds the actual cash investment in a local plant of similar capacity, as follows:

To build a lighting plant complete for supplying 500 arc lamps of 2,000 candle power and 1,000 incandescent lamps of 16 candle power, for the sum of $105,385; the city to furnish a suitable lot on which to erect the station; payment to be made as follows: $60,385 on completion of the plant; $25,000 one year after completion, and $20,000 two years after completion, the engineering company to retain full possession of the plant until the final payment is made, and also to receive from the city the annual sum of $32,500, in equal monthly installments, for the period of two years, to compensate the engineering company for supplying 500 arc lamps for all night and every night street illumination; this being at an average cost to the city per arc light of $65. The city also to carry during those two years not less than $20,000 of fire insurance on the station, and not less than $50,000 of tornado insurance on the entire plant.

The question of municipal ownership being submitted to the voters at a special election, it was carried by a majority of 2,416 in a total vote of 5,176 and the proposition above outlined was accepted and the mayor authorized to sign and deliver the contract. At the previous regular election the total number of votes cast was 13,000, showing that less than one-half the usual number of voters felt sufficiently interested to cast a vote.

As the mayor was signing the contract a taxpayer endeavored to prevent the action, but being defeated he then petitioned the courts for an injunction restraining the city from carrying out its terms of the contract, and the matter is now being argued in the courts. Until a decision is delivered nothing further will be done in building a municipal plant.

But when the contract for lighting the streets at the old rate of $126 expired, the mayor issued an edict based on the authority conferred in an ancient ordinance, that henceforth the city of Des Moines would only pay $75 per year for each arc lamp of 2,000 candle power used all night and every night for street illumination.

Admitting that $75 is a higher rate than the $65 which the engineering firm offers so supply the gas for, let us endeavor to ascertain whether the mayor was justified by the official records at his command in so arbitrarily fixing on $75 as a rate which the local lighting company must accept.

The proposed cost of arc lighting in Des Moines, when the municipal plant is in operation, will be:

Contractor's charge per arc lamp	$65.00
Insurance on plant per arc lamp	1.00
Sinking fund or depreciation at 5 per cent for arc lamp	10.00
Total cost	$76.00

The last official report of the cost of street lighting in Detroit shows that the annual cost to the city of Detroit for each arc light of 2,000 candle power, burning all night and every night, was $89.42, while operating 1,600 arc lights out of a possible 2,000, the remaining 400 being held in reserve. This cost of $89.42 was the total of five items: labor, $43.57; material, $20.62; depreciation, $1.85; interest, $18.28; taxes, $5.10. Depreciation is largely accounted for by maintaining the entire equipment in the best possible condition. But where complete replacement must ultimately follow, a depreciation charge of only 4 per cent. on first cost is entered. The total investment in Detroit is $714,843.76; a 4 per cent. charge on this equals $28,593.75; the assessed valuation is $427,500, calling for a charge of $7,981.43 for taxes.

The municipal plant in Allegheny City has been in service for several years and operates 1,100 arc lights of 2,000 candle power, and nearly 9,000 16-candle-power incandescent lamps. The cost per arc lamp per year is $74.32, divided as follows: Operating expenses, $53.55; interest charges at 4 per cent., $10.73; depreciation charges at 3 per cent., $8.04; taxes lost by city, $2. The cost of the arc plant was $259,258.43; of the arc and incandescent plants, $348,921, the city supplying the land. Included in the operating expenses per lamp, per year, were: Lamp trimming, $8; inspectors, $2; insurance, $1; coal at $1 per ton, $10; supplies, $4.20; repairs to arc equipment, $5.50; office and miscellaneous, 30 cents; repairs outside, $5; labor at station, $7.50; salaries at office, $3.25; carbons, $5; total, $51.75.

Mr. Hunter, the gentleman in charge of the Allegheny plant, has publicly stated that, in his opinion, fair price for commercial companies having overhead construction to charge for street lighting where arc lamps of 2,000 candle power were in service for 4,000 hours, is $80 per year, where good coal costs $1 per ton; if coal cost $2 per ton, $90; and $100 if coal cost $3 per ton. If the circuits in the downtown districts are underground, an increased ratio should be allowed to cover the interest on the increased investment necessary.

The facts regarding the Topeka municipal plant were officially reported in 1896 as follows: "The plant consists of a lot and building by a railroad switch; three boilers and three engines (worked by horse-power); six 30-light Jenney Indianapolis arc dynamos; six circuits with 24 72-100 miles of line, and 33 5-10 miles of wire, supported on 943 30-foot poles; and 184 lamps of 2,000 candle power each, placed 1,100 feet apart one way and 800 feet the other; a test of seventeen lamps showed an average pressure of 23 15-100 volts, and a current of 19 amperes equals 439 85-100 watts, or 1,953 nominal candle power. The lot and building cost $8,559.33; the plant, poles and wire, $46,888.65; total cost, $55,447.98."

In May, 1896, after less than seven years service, the old machinery in the Topeka plant was condemned as wasteful, unsuitable and unserviceable, and was finally exchanged for modern apparatus at an additional cost of $13,772. And in making this exchange only $1,500 in trade was allowed for the old apparatus, which means a depreciation exceeding 10 per cent. per year.

The officially reported total "cost of operating the Topeka electric light plant," from November, 1889, to December, 1892, inclusive, was $54,240.95, or an average cost per arc lamp per month for thirty-eight months of $7.75. The operating expenses are thus itemized, it being stated that "the best lump coal has been used, at an average cost of $2.75 per ton." Coal, $13,924.64; carbons, $2,981.31; globes, $235.80; oil and waste, $642.70; repairs, $4,847.57; insurance, telephone, etc., $1,329.96; pay roll, $19,743.85; interest, at six per cent., $10,535.12; total, $54,240.95.

In other words, Topeka paid during the first six years of municipal ownership, when machinery, circuits and lamps were new and in good condition, and cost of maintenance low, $93 per year for each arc light used in street lighting, not taking into consideration the extra investment necessary to replace old machinery, or the risk that attends all enterprises of like character, plus the loss of water rates, taxes, etc., which a private corporation would have paid. Moreover, there is $70,000 of the taxpayers' money locked up forever.

To recapitulate: The cost per lamp per year in the three most promising plants cited is shown to be officially reported as follows:

Detroit, Michigan	$89.42
Topeka, Kansas	93.00
Allegheny City, Pennsylvania	74.32

Or an average cost of $85 per year per arc lamp.

These are figures that every honest and practical engineer would accept as showing the best that has been accomplished under the most favorable local conditions. For the economical

[1] Read before the Northwestern Electrical Association. Abstract.

administration of the municipal plant in Allegheny has always been worthy of commendation, even by engineers who could not approve of the low allowance for depreciation. And the commission of six citizens under whose wise administration the Detroit municipal plant was placed in operation, and who gave two years' service free of compensation in any form, was guided in all its deliberations by a chairman whose wide experience and practical ability in successfully solving vexed problems arising in large financial undertakings has been amply demonstrated in many ways. And this commission secured the services of a practical electrical engineer of established integrity who had designed, built and operated many electric plants under conditions differing in each case.

In view of these facts from official reports, and of Mr. Hunter's statement that where good steaming coal costs $1 per ton, $80 is a fair price for commercial companies to charge for street lights of 2,000 candle power burning all night and every night, are not thoughtful investors in corporations properties justified in wondering whether this arbitrary action of the mayor in allowing only $75 per arc light supplied by commercial companies was simply a political stroke to gain the applause of unthinking voters? And are capitalists not justified in hesitating to invest a dollar in Des Moines? No state in the Union has a more intelligent population; few states so rich and productive as Iowa. Must all development be arrested for a term of years because a few men would sow the tares of municipal socialism in the hope that through awakening a hatred of all corporations they may reap certain political honors?

ELECTRIC LIGHTING

Electric Lighting For Profit.[1]—II.

BY ALEX. DOW.

A GENERAL DISTRIBUTION SYSTEM.—It is a serious handicap to a station when it is obliged to run two or three separate types of dynamos and to maintain two or three separate distributing systems for the supply of different shapes of energy. The best practice to-day is to furnish incandescent lights, arc lights, and electric motive power from the same dynamos and same mains. This is a subject to be considered in the original plan of the station, but there are instances where old stations have been rearranged with decided financial advantage. When a power load can be had even at the low rates already spoken of, a study of the local conditions should be made with a view to seeing whether a general distribution system will not be a source of profit. To design a new station with anything but such a system is almost criminal.

Supply of Street Railway Current.—There has not yet been devised a satisfactory system whereby a supply of 500-volt current for railway work can be combined with a general lighting distribution. Therefore a proposal that a lighting station should furnish such current must be dealt with as involving a new investment. This investment is always the cost of dynamo and switchboard and usually the cost of an engine. The street railway evening load in winter time coincides with the heaviest load on the lighting system for about two hundred hours per annum. At all other hours the street railway demand is a desirable addition to the load on the boilers, and in most stations the dynamo and switchboard can be cared for without cost for additional help. If the boilers are properly designed to suit the conditions, they may be driven beyond their usual rate during these two hundred hours with greater profit than would be possible if additional boiler capacity had to be installed. Furnishing street railway current appears therefore to be equivalent to the sale of steam to a special engine, and the furnishing of attendants to an additional engine and dynamo, and it should be considered as a business proposition on that basis and not in the same manner as a demand for current from the electric lighting plant.

Street Lighting Contracts.—If street lights can be served from a general distribution system, the rate should be made in the same manner as the rate for any other service from that system. As street lights usually run about four thousand hours a year, a rate made on a scientific basis will be very low in comparison with the rate for ordinary commercial lighting. This is not in accordance with the old practice of making all the profit of the business on a street lighting contract; but it is distinctly in accordance with the more modern practice which will probably become general.

Municipal contracts which can be performed without investment in special machinery are desirable business in that the payment is prompt and absolutely secure, and that the conditions of their performance are clearly laid down in the original agreement. For that reason the tendency appears to be to take such contracts at a very narrow margin of profit.

But when the performance of a street lighting contract requires an investment in special machinery and the building of special lines, such a contract is usually undesirable business. It is impossible under present conditions to secure such prices for street lighting as will return the investment to the stockholders within the term of the contract. The contracts are usually short and there is no security of their renewal. If in dealing with a municipality one were dealing with a business corporation having an established policy, it would be justifiable to take such chances, but our American cities, if they have a policy at all, change it from election to election, and no contractor can tell that the service which was deemed perfect by the Board with whom he made his contract, will not be entirely unsatisfactory to their successors with whom he must make a new contract two or three years hence.

In this respect we have another lot of educational work cut out for us. If we could make it clear to the mass of our citizens that the price for a year's street lighting depended on whether the street lighting plant would be employed next year or would be standing idle, we might have some chance to make close bids, without feeling that we were engaged in a risky speculation. The peculiarly exasperating part of the whole subject is that those same theorists who object to asking for bids on a contract running more than two or three years, are usually ready to lock up the good money of the citizens in a city plant which has to be security for thirty year bonds.

Special Sources of Revenue.—In many localities there are opportunities whereby the power of a lighting plant may be employed in work which is not usually considered as part of the lighting business. An arrangement with a manufacturer whereby machinery required by the plant during evening hours will be used by the manufacturer in the daytime, is often possible. A similar arrangement is made in many places for the joint use of a water power. The sale of exhaust steam for heating purposes is another source of revenue which is frequently neglected.

How Can Business Be Held When Once Obtained.—In these days of competition this subject becomes of the greatest importance. We have against us in every station some competition. In the larger cities we have to meet the offers of opposition companies doing a similar business to ourselves; the arguments of the man who wants to sell isolated electric plants to our best customers, and the ever present cheap service offered by the gas company. In the smaller towns and villages the worst obstacle to the holding of business is the tendency of our customers to economize by cutting down the amount of light used. This tendency is present also in the large cities but is not so constantly in evidence because many city people must use light liberally in order to carry on their business. The whole law and gospel of holding business consists in getting your customers to believe that they receive good value for their money. It is not sufficient that you should believe it; you must convince the customers. But it tends to make your success more certain if you know in your own mind that you really are giving good value. For this reason it is essential that you know what each block of lighting costs; which brings up again the subject of analysis of expenses.

No matter how cheaply you offer to sell your products, it is essential that the customer is satisfied with what is delivered to him. Therefore, if he wants to use arc lights you must see that they are quiet and steady. If he buys current from you wherewith to operate a motor, you must make it your business to see that his motor runs satisfactorily. It is not a part of your contract to do this, but if the motor does not run as it should you will go up there some day and find that he has bought a gas engine. If you sell him current for incandescent

[1]Read before Northwestern Electrical Association, Jan. 19, 1898, at Milwaukee. Abstract.

lighting, you must see that the lamps are renewed before they become dim. If you cannot get the customer to buy new lamps, you had better arrange to furnish renewals free, as most stations now do. If even then your customer is slow about calling for renewals, you had better send one of your men up to change the lamps. Neglect in this respect probably means that there will be a sale of Welsbach burners in the neighborhood of that customer. You must be prepared to send assistance to him when he mixes things so that fuses get blown, and you must send this assistance promptly. This may mean that a man has to idle around the station waiting for trouble calls, but you should not think that man's idleness gives you a chance to economize by discharging him. You should look upon it as the outward and visible sign that your customers are getting good service. And above all, you must take such precautions that your service may be relied upon by all who employ it. There is nothing that does so much to damage the business of a station as a reputation for unreliability.

Conclusion.—In closing I wish to say that I am preaching no doctrine which I do not believe, or which I do not try to follow. Neither do I imagine that the stations represented in this association are less carefully planned, or less efficiently managed than those of the rest of creation, that I should address myself to you rather than to others. But it is by electric light men and no others that the advice must be given to those who need it. And each of us has the opportunity at some time to counsel with the man in the next town of whom we have been speaking. While I was in the act of preparing this paper I was asked for advice in just such a case and gave verbally just the same advice that I was putting in writing for presentation to you.

This is a final summary of the opinions I have presented:

(1) The electric lighting business should pay as a reasonable profit, approximately the same rate as any manufacturing business which has similar risks. This profit should be paid after the expenses of operation, maintenance and depreciation shown by annual inventory have been provided for.

(2) Rates for electric supply should be so adjusted that each unit sold will pay its share of operating and standing charges, and in addition thereto a uniform proportion towards profit. No business should be done at a loss and no business should pay more towards profit than its proper share.

(3) Every class of business that can be profitably done should be obtained. Business that improves the load factor should be taken if it can be obtained at any price greater than its share of operating and standing charges, because the improvement of the load factor reduces the amount of standing charges to be borne by existing load.

(4) Business once obtained should be kept by careful study of and prompt attention to the requirements of each customer. It is not possible in the present stage of electric development for an American electricity supply company to limit its interest in the supply to its delivery on the customer's premises. It must do much work in order to secure that the customer uses the supply to the best advantage. It is not sufficient that a customer should be well served, he must also be well pleased.

(5) There is need of educational work to be done among electric light men, among municipal authorities and municipal theorists, and among our own customers. It is our interest that this educational work should be done and as it does not appear to be the duty of any other person to do the work, we will have to do it ourselves.

How to Prevent Arc Lamps from Freezing.

BY WILLIAM FOWDEN,

Superintendent Camden, N. J., L. & H. Co.

I HAVE heard a number of complaints from central station men that they have a great deal of trouble from lamps freezing up in sleet storms. We experienced the same trouble until we hit upon the following plan. We take a number of thin sheets of cardboard and punch a hole in them the same size as the carbon and if the trimmer thinks that things are going to freeze he slips one of these small pieces of cardboard on the upper carbon of the early side of the lamp. This will act as a shed for the water, and we find very few cases where the lamp will freeze up where this has been used. I feel sure that our experience will help more than one central station man out of this trouble.

English Incandescent Lighting and Railway Statistics.

THE yearly supplement table of electrical central stations of the United Kingdom, published by the London "Electrician," contains some remarkable statistics which form the basis for the following comparison between the present output of the various stations and that of previous years: Fig. 1, which shows the rate of increase of the lamp connections of the London companies and municipalities since 1890, gives evidence of a very flourishing condition of affairs. Although the Metropolitan still leads in the number of lamp-connections, it was not to be expected that the enormous increase of last year would be repeated, but still an addition of 45,000 8-c. p. lamps in the year shows that the saturation limit is still very far distant. The greatest increase—50,000—can be claimed by the City of London Company, its curve having already passed that of the Westminster Company, although the lamp-connection of the latter has also shown a healthy improvement. The St. Pancras curve is "looking up" again this year, and the only one

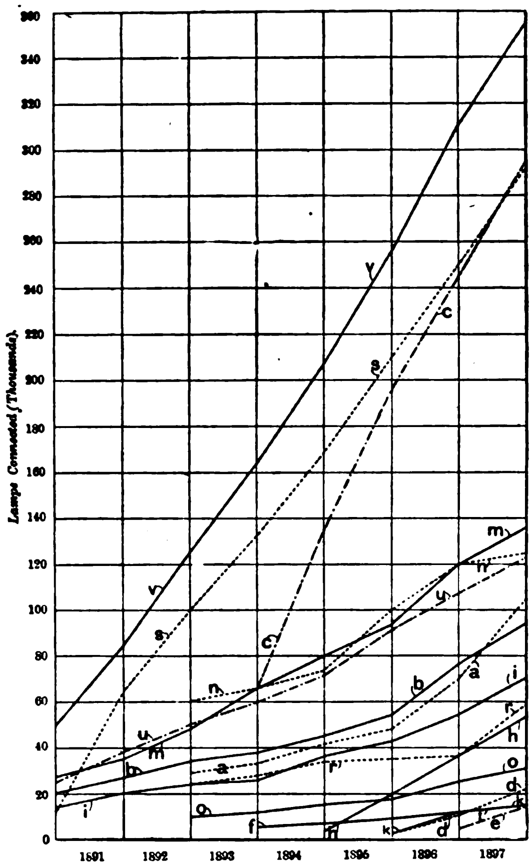


FIG. 1.—LAMP CONNECTIONS IN LONDON.

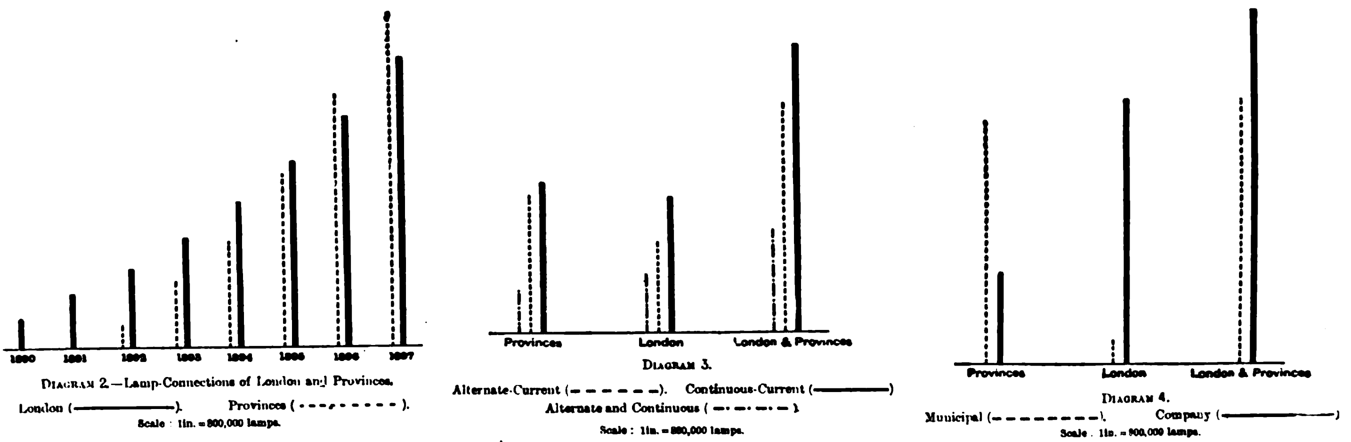
a, Charing Cross Company; b, Chelsea Company; c, City of London Company; d, County of London and Brush Provincial Co. (Clerkenwell); e, County of London and Brush Provincial Co. (Wandsworth); f, Crystal Palace Company; h, Hampstead Vestry; i, House-to-House Company; k, Islington Vestry; m, Kensington and Knightsbridge Company; n, London Electric Supply Corpn; o, Notting Hill Company; r, St. Pancras Vestry; s, Westminster Corpn; u, St. James and Pall Mall Company; v, Metropolitan Company.

which shows possibly transient signs of approaching saturation is that of the London Electric Supply Corporation.

Fig. 2 shows that the provinces are increasing their lamp-connection still faster than London. During 1897 the London total became 1,831,000, an increase of 369,000 since the end of 1896, the increase in the previous year having been 283,000. The total for the provinces is 2,129,000 at the end of 1897, showing an increase of 527,000 during the year, as compared with 502,000 during the previous year. The total for the whole of the United Kingdom is therefore very nearly four millions of 8-c.-p. lamps or their equivalent, this number being undoubtedly considerably exceeded if private stations be taken account of.

Owing to the number of stations which supply both continuous and alternating currents, the "Electrician" has been obliged to make a change in Fig. 3 this year. The aggregate lamp-connections of the stations supplying only continuous current is, it is seen, considerably greater than that of the stations which supply nothing but alternating current; yet it is probable that



FIGS. 2, 3 AND 4.

more alternating current is being supplied than continuous, as the majority of the "mixed" stations have only recently adopted continuous current for special purposes. The height of the chain-dotted line for London is, for instance, almost entirely due to the Metropolitan Electric Supply Company, the continuous current connection of which is, however, but a small proportion of its total load.

Fig. 4 indicates further additions to the municipal load, especially in the provinces, new municipal stations having been opened at Harrogate, Torquay, Wakefield, and Wallasey during the year, and in London at Hammersmith.

Tables I., II. and III. give the figures which are shown graphically in the figures 3 and 4.

TABLE I.—DETAILS OF LAMP-CONNECTIONS IN LONDON AND PROVINCES.

LONDON (1,83c,995)	MUNICIPAL (149,410)	—	72,693
		∽	76,717
		$\underline{\sim}$	none
	COMPANIES (1,681,585)	—	798,588
		∽	505,050
		$\underline{\sim}$	377,947
PROVINCES (2,128.655)	MUNICIPAL (1,546,282)	—	733,554
		∽	538,205
		$\underline{\sim}$	274,523
	COMPANIES (582,373)	—	229,104
		∽	343 669
		$\underline{\sim}$	9,600

TABLE II.—APPROXIMATE LAMP-CONNECTIONS OF ALTERNATING AND CONTINUOUS-CURRENT STATIONS.

—	$\underline{\sim}$	∽	—	TOTALS
London.............	378.000	582,000	871,000	1,831,000
Provinces......... ..	284,000	882,000	962,000	2,128,000
Totals.........	662,000	1,464,000	1,834.000	3,959,000

TABLE III.—APPROXIMATE MUNICIPAL AND COMPANY LAMP-CONNECTIONS.

—	MUNICIPAL.	COMPANY.	TOTALS.
London.................	149,000	1,682.000	1,831,000
Provinces..........	1,546,000	582,000	2,128,000
Totals	1,695,000	2,264,000	3,959,000

The "Electrician," from which the above diagrams are taken, has also issued a map of the central stations of the United Kingdom, showing their location, whether they employ the continuous or alternating current and indicating the stations owned by private companies and municipalities. This map shows that the space distribution of the stations has departed from uniformity in a marked degree.

The Table of Electric Railways and Tramways shows that there are 23 lines in operation in the United Kingdom, that the construction of 25 others is sufficiently far advanced to make it probable they will commence running before the year is ended, and that there are now projected schemes for the construction of 10 underground electric railways in London, and 48 light railways and tramways in London and the provinces. The lines in actual operation, together with such as will commence running in a very few weeks comprise over 150 miles of track, while the aggregate track mileage of the lines working and in course of construction approximates 400 miles.

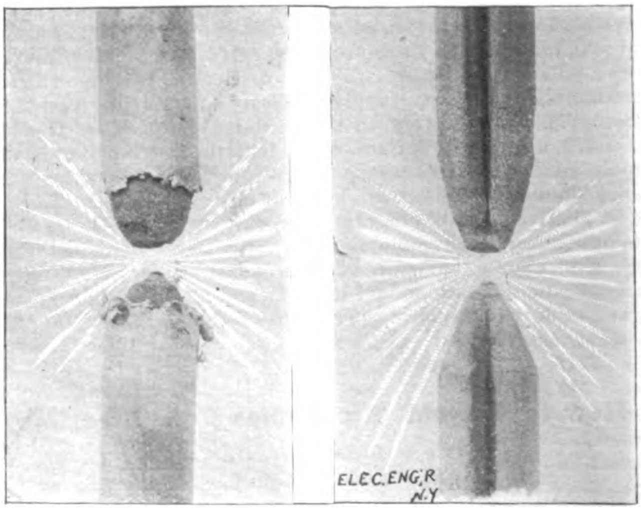
By far the greater number of the concerns embodied in the table, whether as being in operation, in process of construction, or merely projected, relate to the overhead trolley system. In the great field of the electrical equipment of town roads neither the battery car nor the conduit system has advanced, and no instance exists of a public railway being worked on a surface contact system as regards the United Kingdom, while the third-rail conductor system has been reserved exclusively for underground and overhead railways.

The "Open Arc" Grooved Carbon.

THE "open arc" carbon is the name which has been given to a new and interesting form of arc carbon recently brought out, and for which a number of valuable qualities are claimed, not met with in the ordinary form of solid carbons.

The distinguishing feature of this new type of carbon is a longitudinal groove running from one end to the other parallel with the length of the carbon, as shown in the accompanying figures.

By the use of this carbon it is claimed, first, that the vortex action of the current is checked by the groove, and the crater



FIGS. 1 AND 2.

of the carbon is held stationary at the apex of the pencil; and what is still more important, is that the size of the white light crater is nearly double that of any other carbon. This is explained by the inventor thus: With the solid or cored carbon that part of the white light crater is only visible which is on the apex of the carbon; with the grooved carbon, however, the crater appears as well on the sides of the segment cut-out of the carbon as on the end, almost doubling its light rays.

It is also claimed that with a solid or cored carbon, the maximum heat point is the center of the carbon, hence, the

center of both carbons disintegrates too rapidly, leaving walls on either side which, a large portion of the time, obscure the crater, and build up on the lower carbon to a point that shuts off the rays from traveling downward. With the "open arc" carbon, it is claimed that the grooves cut the material from the center, leaving nothing there, and throwing the maximum heat point to the sides of the pencil, thus giving the lower stick a cone-like form, and allowing all the rays to travel downward.

The accompanying engraving illustrates this action, and was made from photographs taken from two sets of carbons burning side by side in high tension lamps, both sets of carbon being coppered. Another point made, is that a ⅝-inch carbon, solid or cored, while desirable for a long run, is a poor light developer; but with the "open arc" carbon, this result for the reasons before given, does not obtain.

This new form of carbon is said to increase the illuminating power of the arc from 30 to 40 per cent., without any increase in current consumption, and if this be so it unquestionably has claims to recognition. We may add that the new product is being introduced by the Open Arc Carbon Co., of 108 Fulton street, New York, and that a number of prominent electrical men are interested in the company, among them Mr. Charles A. Lieb and Mr. Caleb H. Jackson.

ROENTGEN RAYS

An X-Ray Picture of a Loaded Lebel Rifle.

PROFESSOR RŒNTGEN has shown that the X-rays are disseminated in the bodies which they traverse similarly to light passing through distorted media. Recently the importance of this discovery has been more fully recognized in regard to the disturbances which are produced in certain radiographic operations.[1]

When a very opaque object, like a large watch, is interposed between a powerful Crookes tube and a photographic plate, the X-rays are powerfully disseminated in the space which they traverse behind the plate, making impressions on the back, that is the side of the glass which carries the sensitive film. This impression, or shadow, increases uniformly with the duration of exposure. The result is that a relatively short exposure gives a faint silhouette of the mechanism of the watch, but the impression seems a trifle blurred. The value of the impression at first increases with the time of exposure, but this reaches a certain limit when the impression rapidly grows bigger under this double radiation and becomes more and more gray until all the details of the silhouette are lost.

It is evident that one can prevent the shadow of the return rays when, in getting ready for the experiment, a sufficiently opaque screen is placed against the back of the sensitive film. A sheet of lead half a millimeter in thickness is ordinarily sufficient. This thickness can be increased in exceptional cases.

This precaution is not necessary when a little less powerful tube is employed, because the glass on the back of the plate is then sufficient to arrest all the return rays. For the radiographs of very opaque objects requiring very long exposures, placed in front of powerful tubes, it has been found expedient to use a sensitive preparation of loose films of double commercial gelatine and lay them on lead sheets of the same shape, enclosing the whole in black paper whose object it is to arrest the ordinary rays of light.

[1]Buguet French Academy of Sciences, November 2, 1896; August 16 and 25, and November 8, 1897.—Roentgen, L'Eclairage Electrique, July 17, 1897.

The role played by the back screen is clearly brought out in a radiograph of a large watch obtained after an exposure of two minutes at a distance of 12 centimeters from a very powerful tube, only half of the back being protected against the return rays by a metallic screen. The protected part gave a very detailed silhouette of the interior mechanism, whilst a thick shadow conceals nearly the entire other half.

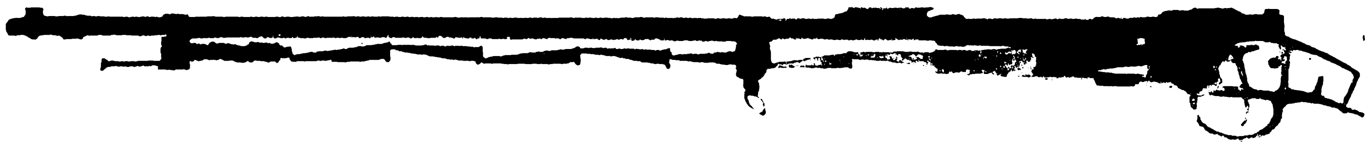
This may explain the numerous failures which have been met with in even the best radiograph work designed for the study of very opaque substances in the human body and of metallic objects generally.

By using a back screen, there are obtained, for example, all the details of construction of cartridges. The hunting cartridges, for example, allow the experimenter not alone to see the arrangement of the charge, of the wadding and the nature of the powder, but also the irregularity of the metallic socket, the form of the capsule and the position of the trigger.

A copper pistol and a revolver which will not produce a shadow by the old methods, exhibited the balls clearly in place when the back screen was employed as described. This has helped the experimenter to obtain also several radiographs of a Lebel gun by relatively short exposures, these having been, at 20 centimeters, 10 minutes for the locking parts, and 1 minute for the other parts. Referring to the figure, one can clearly see through the two steel jaws, the swinging tray, and the cartridge which it contains ready to pass into the barrel. Eight cartridges can be distinguished at different angles and all pressing in line against the coiled spring which pushes them forward.

One can finally distinguish that these cartridges are of the kind used by shooting clubs, as the powder is granulated and not "ribboned" like that which M. Vieille uses for cartridges for warlike operations.

The above data is part of an article contributed to "La Nature" by Abel Buguet, Professor at the School of Sciences and the School of Medicine of Rouen.



RADIOGRAPH OF A LEBEL RIFLE.

The Effect of Röntgen Rays on Plants.

PROF. G. F. ATKINSON, of Cornell University, publishes in the January 7 number of "Science" a "Report upon some preliminary experiments with the Röntgen rays on plants," from which the following extracts are taken: Since it is a matter of some interest to know what influence, if any, the Röntgen rays would exercise on plants, I undertook a series of somewhat extensive preliminary experiments, to determine what lines of investigation might profitably be carried on should there be marked indications of any response to possible stimuli from this source.

The author then describes twelve experiments in which he used the following substances: Leaves, seedlings of corn, a begonia plant, a caladium plant, species of mucor, several forms of chromogenic bacteria, a motile bacillus, sensitive plants, etc., and draws the following conclusions: It is thus seen that plant tissues absorb the Röntgen rays quite freely, and it is singular that there is not a more marked influence on growing parts, especially that there are no visible external injuries, even when the parts are exposed at close range a large part of the time during several days, since the general impression is that the rays, even with comparatively short exposures, are injurious to the human tissues.

The longer his experiments continued the more mysterious the whole subject seemed. On a dark night, when the electric light rays were intercepted by a black screen, exploring the field with a fluoroscope there was an abundance of light, flashing and quivering with the variations in the electric transmission through the tube, penetrating, and yet capable of absorption to a considerable degree. That it should present no easily discernible influence for the time during which the work continued was cause for profound surprise.

VOL. XXV. NEW YORK, FEBRUARY 10, 1898. No. 510.

Possibilities and Limitations of Electric Traffic.

IN the current issue of the "Engineering Magazine," Mr. Frank J. Sprague concludes his exceedingly interesting essay on the possibilities and limitations of electric traction, already noted in these columns. In this portion Mr. Sprague, leaving the question of city and suburban traction, takes up the larger problem of the main line. As he shows, it is no longer a question as to whether a locomotive can be built of suitable power and reliability, and sufficient energy could be transmitted, nor a mere question of power economy with the possible advantages to be gained by utilizing a convenient water power. Other elements have entered into the discussion at the present time. Among these Mr. Sprague notes, first, the question of signaling, and on this point he believes that it is safe to assume that a practical system can be devised. As to the matter of brakes Mr. Sprague ventures to prophesy the not distant advent of an entirely successful electro-mechanical automatic brake. Mr. Sprague has been a pretty good prophet in the past, and in this case he probably goes very safely, admitting, as he does, that he is now working on plans for just such a brake, utilizing his experience on a similar apparatus in connection with his elevators. As to the conditions of current supply, we are glad to note that Mr. Sprague lays particular stress on the value of the storage battery, not so much as a storer of energy as a regulator. Still there are cases in which the storage battery enters directly into the problem as a reservoir of energy, as, for example, at Buffalo, where, according to Mr. Sprague, Niagara power, in order to compete with coal at $1 per ton, had to be supplemented by a storage battery charged during the entire twenty-four hours of the day. Mr. Sprague also tells us that some months ago he made definite proposals to put on the Manhattan Elevated Roads in New York two or more storage battery stations, supplied by rotary converters operated from a multiphase transmission plant, or by steam engines and dynamos of moderate capacity locally installed. Given as available all the apparatus necessary to operate a main line electric road, Mr. Sprague then inquires how far a trunk line is warranted in the adoption of electricity. Broadly stated the answer depends entirely upon the conditions of the traffic. As to the much-talked-of long distance, high speed electric railways, such as from New York to Chicago, devoted exclusively to passenger service with all the existing possibilities of passenger traffic, Mr. Sprague believes that such a line could not return interest on the investment, no matter what the rate of speed determined upon, nor how attractive it could be made. This must be a sad blow for many enthusiasts, who dreamed of breakfasting in New York and lunching in Chicago, and the statement coming from such an optimist as Mr. Sprague himself should put a quietus on many of the roseate descriptions of the traveling facilities of the future. Mr. Sprague also sounds a note of warning when he points out that in calculations looking to the adoption of electricity on main trunk lines the fact must not be lost sight of that there is an increase of investment as an offset to any saving in transportation account and cost of power. In other words, that while fewer electric locomotives could safely do the work of a given number of steam locomotives, still, considering all classes of equipment, it is safe to assume that the cost of the power equipment supplied to the rolling stock will be fully as much for any electric system as for steam. It is, therefore, only when the saving in fuel, transportation, wages, lower depreciation, and gain of business will insure a material dividend on the increase of investment that such a step would be advisable. This no doubt may appear to be cheering news to many steam roads which still dread the change to electricity, but it would be well for them not to lull themselves into the belief that the conditions as here outlined are but infrequently met with. No doubt on sections of light traffic such conditions would apply, but there are others, not few in number, in which the reverse might prove to be the case. Again, as Mr. Sprague points out, increase of traffic requirements, especially under the spur of competition, are continually making improvements necessary, while the abolition of grade crossings and the adoption of rock ballast and duplication of trackage all tend directly towards electric methods. Even where a complete system is not equipped electrically, Mr. Sprague points out that electric motors may be used profitably to assist steam trains over heavy grades. Apropos of the predictions as to the employment of electric feeders for steam main lines, Mr. Sprague makes the somewhat heretical observation that he expects to see in some instances the reversal of this idea. That is to say, under certain conditions the outlying and infrequently served portions of a system may be steam, while the main section with the concentrated traffic may be electric. The argument is, however, quite logical. Of course, Mr. Sprague lays particular stress on the value of the multiple unit system of control which he has developed, and which is now in such successful operation in Chicago. Taken altogether Mr. Sprague's essay is an excellent statement of the problem, and to his conclusions little exception will be taken by those competent to pass an opinion thereon. We recommend its study, particularly to our steam railway friends.

Electric Lighting and Traction in England.

ON another page we present some central station statistics, compiled by the London "Electrician," from which very interesting conclusions may be drawn. The diagram indicating the current supplied by the various London companies for lighting purposes shows an improved state of affairs. Especially in the provinces, the use of the electric current for lighting is finding more and more favor, the total being 2,129,000 lamps in 8 candle power lamp equivalents, an increase of 527,000 during the year 1897. The total for the whole of the United Kingdom is very nearly four millions of 8 candle power lamps or their equivalent, that is excluding isolated plants. It appears from the diagrams that the alternating current predominates over the continuous current, and the number of mixed stations is surprisingly on the increase. The map accompanying the tables shows, as may be expected, a very uneven space distribution of the central stations, the greatest density being around London, Liverpool and Manchester. There are only eight central stations in both Ireland and Scotland, and one in the course of construction in each. There are about an equal number of municipal and private company plants, but of the twenty-seven central stations in the city of London, only six are owned by the municipality.

Turning now to the statistics of electric railways in Great Britain and comparing them with similar data published last year, we find that during 1897 electric traction in the United Kingdom has made rapid strides. However, to the electrical engineer on this side of the Atlantic it is cause for astonishment to learn that there are only twenty-three lines in operation in Great Britain, and twenty-five in the course of construction; besides ten underground electric railways projected for the city of London as well as forty-eight light railways for London and the provinces. Of the twenty-three lines in operation, eight employ the center overhead trolley, six the side trolley, five the middle rail, and one each of the following: Third rail, battery, side rail and slotted conduit.

The lines in actual operation, together with such as will begin running in a very few weeks, comprise about 150 miles of track against 15,000 miles in the United States. While this comparison is certainly striking, and we venture to say, ludicrous, it is a source of gratification to be able to record the fact that our English brethren are constructing a larger number of electric railways this year, than the total number in operation in Great Britain at the present time. "There is life in the old dog yet."

The New York Edison Co.'s Annual Report.

THE Edison Electric Illuminating Company of New York, being the largest electricity supply company in the world, and the city within which it operates being the metropolis of the United States, as well as the center of financial and commercial interests, it always appears proper to use the company's report of a year's operation as a safe criterion for the electric lighting industry and general prosperity of this country. If this be so, it is encouraging to note that the record of 1897 stands supreme in the history of electric lighting and the use of the electric current for power purposes, while the outlook for 1898 is most hopeful and encouraging.

On another page we give an extended abstract of the very exhaustive and able report of First Vice-President Bowker, which shows that the business of the company has had a steady increase with gratifying financial results. The progress of the company in the eight years of its existence shows six times the number of customers, seventeen times the installation, eight times the maximum output, on but fivefold the capital, with over seventeen times the gross and nine times the net income. The company has now 7,313 Edison customers, installations of 346,723 incandescent and 4,775 arc lamps, and 19,364 horse power in motors, being an equivalent of 696,370 16 candle power incandescent lamps, exclusive of 60,068 high tension and 80,928 "breakdown" connections, equivalent in all to 837,366 16 candle power lamps, which number will probably reach the 1,000,000 equivalent mark in 1900. Moreover, 100,000 amperes maximum output was reached in 1897; the company has $14,500,000 in round numbers, loan and share capital; its gross income for combined systems was, in 1897, $2,486,636, and its net without depreciation charges $1,261,497 or 50.7 per cent., or, deducting depreciation charges, $1,117,497, or 45 per cent.

For the Edison system only, the gross station returns have increased 13.7 per cent., and the general and operating expenses have increased 10.9 per cent. Nearly 1,000 service connections were added during 1897, and we note the change from chemical to mechanical meters so as to eliminate as largely as possible all errors due to incorrect measurements of current which have now been reduced to 1/5 of 1 per cent. The low tension arc light service has been greatly extended, the number of arc lights having been increased from 3,225 to 4,775; and in this direction remarkable developments are expected in the near future. No fewer than 236 inclosed arc lamps were installed, a contract for 300 more for city lighting has just been closed, and a number of city buildings and armories have lately been furnished with lights. We again wish to record the satisfactory relations which exist between the company and its employés. It is a certain guarantee of efficient work on the part of the latter.

However, the most significant, and to the consumer the most important item in the report is the chapter on rate reduction, which was supplemented on February 1, by circulars issued by the Edison Company and the companies which it controls. It was only last October that a circular was issued announcing a reduction of rates for long-hour use of the electric current, and containing the statement, that if the arrangement proved satisfactory, a discount would also be extended to the small consumer. This has now come to pass, and in the new circulars of the allied Edison, Harlem and Manhattan companies, who believe that the reductions in the prices of current will broaden their fields of operation and thus make still further reductions possible, remarkably low rates and large discounts, on experimental bases, are quoted to the consumer, large and small.

The new discounts of the Edison Company, whose base price for incandescent lighting is 1 cent per 16 candle power lamp hour, including renewal of lamps, range from 5 per cent. for $100 to 40 per cent. for $1,000 or over gross monthly bills. An additional discount of from 5 per cent. for 50 hours to 25 per cent. for 150 hours monthly average use of each 16 candle power lamp (equiv.) installed, is quoted. The base price for arc lighting is 10 cents per 8-ampere lamp hour, with discounts of from 10 per cent. for 100 lamp hours to 35 per cent. for 1,000 arc lamp hours, and an additional discount for long-hour use of from 5 per cent. for an average burning of 100 hours to 15 per cent. for 200 hours average monthly burning for each lamp installed. A special discount of 10 per cent. is allowed to consumers owning their arc lamps. Power service is supplied at a base price of 10 cents per horse-power hour with discounts ranging from 20 per cent. for 100 horse-power hours to 50 per cent. for 1,500 horse-power hours, 55 per cent. for 5,000 horse-power hours and 60 per cent. for 10,000 horse-power hours. A wholesale price on the kilowatt basis is made to consumers using not less than 2,500 kilowatt hours per month. Heating is supplied at power rates and storage batteries also when used outside of maximum hours, and in large quantities at 6 cents per kilowatt hour with special discounts to large consumers.

In order to make a fair test of the expediency of varying rate methods in the various sections of the city, the Manhattan Electric Light Company and the Harlem Lighting Company, both controlled and operated by the Edison Company, have issued circulars similar to the above in which they quote very liberal discounts to their consumers, subject to change after a period of three months. The new rates of the Manhattan Company are as follows: For the first two hours' daily consumption 1c. per lamp hour, for the second two hours' 1/2c. per lamp hour and for all over four two hours' consumption 1/4c. per lamp hour. The discounts of the Harlem Company on a base rate of 1c. per lamp hour are: For 50 hours' average monthly burning per lamp 5 per cent., and for 60, 75, 85, 100, 125, 150, 175 and 200 or over, discounts of 10, 20, 25, 30, 35, 40, 45 and 50 per cent., respectively.

Electricity can be furnished, when used through a number of hours each day, for a lower cost than gas and the object in giving these different rates to the consumers is to find out which one of the proposed methods commends itself most to the public. We hail the new announcement of this progressive company with delight, and believe that the sharing of profits with the customer will have the effect of a more extended and varied use of the electric current than ever. It is but another evidence of the far-sightedness and public spirit of the Board of Directors and of the ability of the general manager, Mr. J. W. Lieb, Jr., who are all entitled to the gratitude of the electrical profession for thus placing the electric current within the reach of all who desire to use it for lighting, power, and other commercial and domestic purposes. It is liberality of management which must reap its own reward.

A Fifty Thousand Volt Transmission At Telluride.

IT is a fact not generally known that a transmission at 50,000 volts was some time ago tried for a period of two weeks from the water power plant at Telluride, Col., to the Gold King Stamping Mills there. The Telluride transmission is well known as one of the earliest in this country. The first plant consisted of a single phase 3,000 volt alternator with direct transmission to a synchronous motor three miles away. This has since been replaced by a three-phase transmission with step-up and step-down transformers.

It was about the time the change was made that the experiment was tried of transmitting at 50,000 volts three-phase alternating current. The transformers used were those now employed on the three-phase transmission there, said transformers being arranged to give a number of different voltages from 50,000 down according to the way they are connected.

As said before, this transmission at 50,000 volts three-phase current was kept in service for about two weeks and no accidents occurred during the time. The line consisted of galvanized iron telegraph wires supported on glass insulators. It was found that the self-induction afforded by the iron wire had a beneficial effect in counteracting the capacity of the line. The experiment was not continued for a longer time because a rainy season came on and proper provisions against lightning were not at hand. The transmission line is three miles long and runs up a steep mountain side and over a very wild country. It was illustrated some four or five years ago in our pages at the time of its first installation, in the early days of direct current power transmission. The many inquiries we receive as to transmissions above 10,000 volts will be answered to some extent by the information now given.

MISCELLANEOUS

The Voltex Process of Electric Welding, Soldering and Lead Burning.

It has long since been recognized that for very many purposes, electric welding offers numerous advantages over the ordinary method of welding in a smith's fire, and within the last ten years several systems have been devised, and have achieved more or less success. Many attempts have been made to make use of electricity for brazing purposes, owing to the numerous advantages which a simple electrical method would have over the ordinary gas and coke brazing hearths, but hitherto all these attempts have been failures as far as practical work is concerned.

The Voltex process, developed by The Electric Metal Working Syndicate, Ltd., 61 and 62 Gracechurch street, London, E. C., is said to have overcome these difficulties and made electric welding and brazing practicable in the smallest as well as in the largest works.

The apparatus consists, as will be seen from Figs. 1 and 2, of a carbon holder and a pair of carbon electrodes. In using the apparatus an arc is struck between the electrodes, and owing to the material of which these are made and their arrangement in the tool holder, a powerful flame like that of a gas blowpipe, but of much greater range of temperature, is projected from between the adjacent ends of the electrodes, and is directed upon the material to be heated.

The portion of this "blow-pipe flame" nearest to the carbon points is of the highest temperature obtainable by artificial means and its temperature gradually decreases as the distance from the electrodes is increased.

The workman, therefore, by merely varying the distance of his work from the electrodes can apply to it a blow-pipe flame of a temperature ranging at will from that of the arc itself down to a temperature comparable to that of an ordinary gas blowpipe. By varying the voltage, or electric pressure, by means of a regulating switch, the power of the blast can be still further

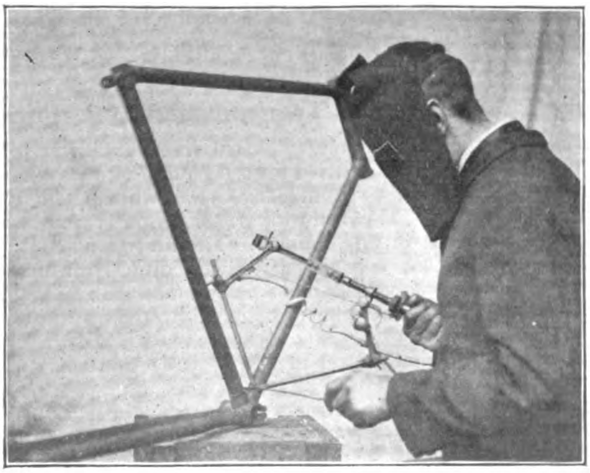

FIG. 1.—WORKMAN BRAZING CYCLE FRAME WITH BRASS WIRE SEEN IN HIS HAND.

increased or diminished at will. The process is thus an extremely simple one and the tools may be moved from place to place in the workshop, or factory, as may be convenient.

The advantages claimed for the process are:

1. It is so simple that any workman can use it efficiently after a very little practice, the tools being as easy to use as a soldering iron. 2. It is economical. 3. It requires practically no outlay for installation, provided a source of electric supply is available. 4. The apparatus is such that it can be taken to the work instead of the work having to be taken to the tool. 5. Work can be executed which is impossible by other methods. 6. Malleable iron and steel, as well as cast iron, can be treated by the process, and, if requisite, raised even to the fusion point without being rendered hard or brittle.

The process has been successfully employed for welding wrought iron and steel; joining cast metal sections, cycle brazing, general brazing, welding and brazing girders and other iron work in locomotive and railway shops, cable manufacture and trolley work, tempering tools, brazing of band saws, work in connection with ship building, brazing of copper steam pipes and boiler tubes of brass and copper. In iron ship building the rivets may be inserted cold and can therefore be used of the

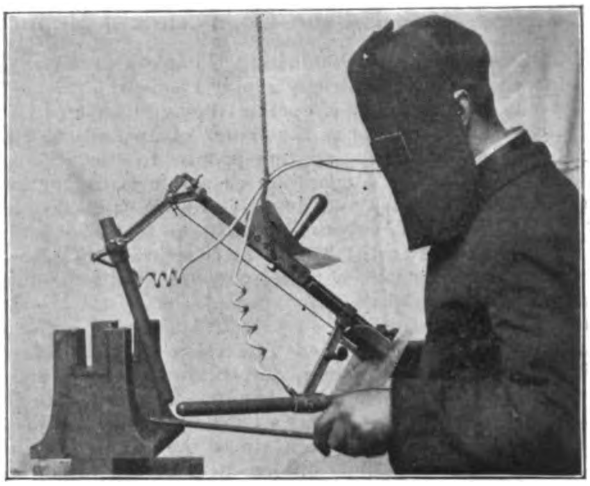

FIG. 2.—WORKMAN FILLING UP FLAWS IN IRON CASTING. (By means of carbon rod held in hand, small pieces of cast iron are pushed into the hole after metal in latter begins to run.)

full size of the holes drilled to receive them, the heads being brazed over, after heating by means of a voltex tool.

When an installation has to be put in expressly, the alternate current is preferable, as with the alternating current both carbons remain pointed, and, of course, burn evenly away; but the great advantage is that the voltage can be altered with great ease without any great waste by means of a choking coil. For brazing work forty-five to fifty volts are generally employed, and for heavy welding and filling up flaws in large iron and steel castings from fifty to fifty-five volts are used. We are indebted to Mr. G. W. de Tunzelmann, inventor of the system, for photographs and details.

The Lamina Accumulator.

The Lamina Accumulator, manufactured by the Elieson Lamina Accumulator Co., Ltd., London, belongs to the Planté type of accumulators. It is generally supposed that for storage capacity, per unit weight of plate, accumulators on Planté's principle cannot compare favorably with pasted cells. The "Lamina" plate has demonstrated to the contrary. The following is a brief description of the construction of the cell: Lead is received in the form of rolls 8 to 10 inches wide and of thicknesses varying from 1-64 to 1-32 inch. This lead is first perforated, in a machine specially designed to give the amount of perforation per square inch which experiment has proved to be the most satisfactory. The lead then passes to the corrugating machine. After corrugation it is cut up into sheets of the required size. These sheets are surrounded by a large sheet of the same material which entirely envelops the sheets. The capacity of the plate depends upon the number of sheets or laminæ used. The corrugations are placed alternately, vertically and horizontally or at an angle if desired. The plate has now to have a number of holes punched in it. The number of course varies according to the dimensions of the plate. Into these holes rivets are placed, and afterwards these are fixed by means of burning; the plate is also "stitched" along the joint of the outside sheet, and tops and bottoms are "burnt" on. The plate is now ready for formation. This takes about 36 hours and the effectiveness of the process may be judged from the fact that during the first 24 hours no gases are evolved which shows that the whole of the current is utilized in converting the surface lead into active material. After formation the plates are reduced and if the plate is intended for a negative it is then complete; if it is intended for a positive, it must be oxidized. Both these processes take from 36 to 40 hours. The plate is now

finished and cells may be built up according to requirements. During formation the outside sheet is protected, thus it is not attacked to anything like the extent that the inside or unprotected sheets are. The advantages of this are of course that it retains its mechanical strength, and also conductivity. The mechanical strength of the plate is very good, buckling being practically impossible, the corrugations adding greatly to the strength. Extremely high rates of charge and discharge are possible with the "Lamina" plate. The cells may be charged and discharged with perfect safety in an hour. The cells stand well

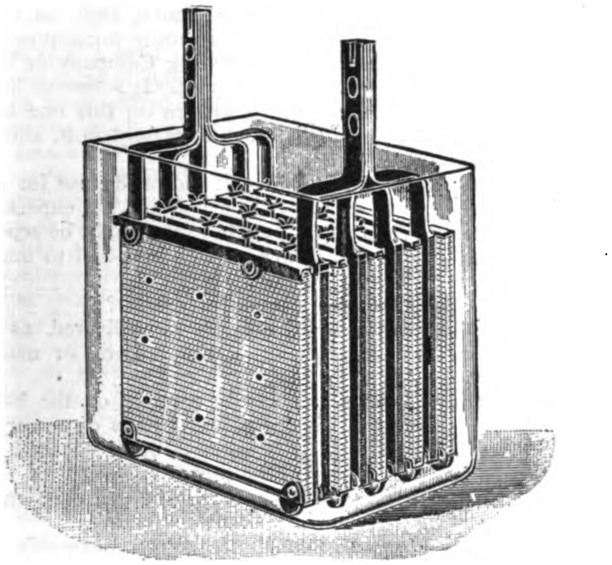

FIG. 1.—LAMINA ACCUMULATOR; LIGHTING TYPE.

the severe work imposed upon them when used for traction purposes. It will be obvious from the method of construction, that enormous surface is obtained, and free circulation of acid to every part of the plate. Plates of any size or shape can be built just as easily, as the company's standard sizes. Thus a good many "Lamina" positives have been supplied for renewing pasted positives.

The following is an abstract from a report rendered by Prof. S. P. Thompson, F. R. S., D. Sc.: "This accumulator is specially designed for traction work, and has a very high output for its weight, as well as great durability. Under normal conditions its capacity for storage of work is about 14 watt hours per pound weight (gross) of the cell. This figure is as high as that of any accumulator yet in the market, and higher than that of any accumulator of equal durability. Or, to put it in another

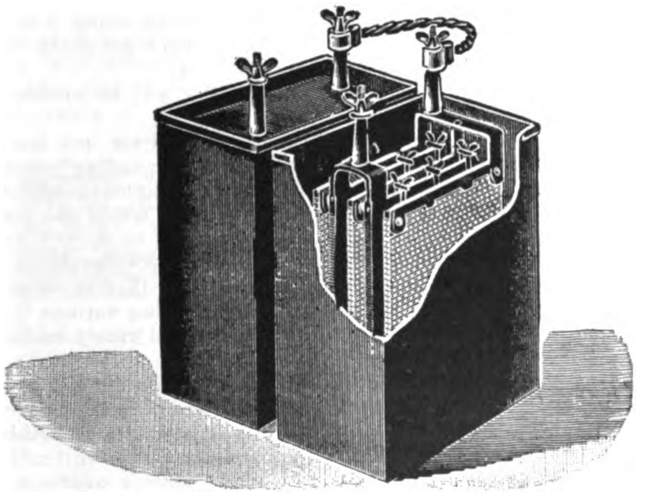

FIG. 2.—LAMINA ACCUMULATOR; RAILWAY TYPE.

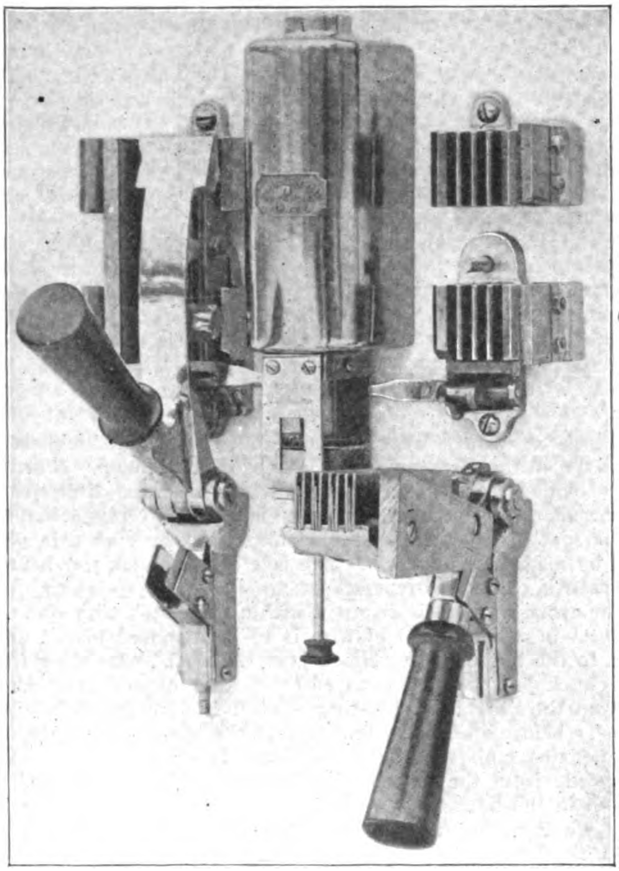
way, taking it as being as high as that of any other accumulator, these cells have a greater durability."

Reports of a similar nature have been submitted by Messrs. C. E. Spagnoletti, M. I. E. E., and Haydn I. Harrison, M. I. E. E. The type of cell shown in Fig. 1 is made for lighting purposes, and one of these cells having a capacity of 320 ampere hours, weighs 71 pounds. Fig. 2 shows the motor car type which is incased in ebonite boxes. The total weight of one of these cells having a capacity of 100 ampere hours, is 27 pounds complete.

Ward Leonard D. H. Circuit Breakers.

THE accompanying cut shows the new type of D. H. Circuit Breaker, manufactured by the Ward Leonard Electric Company, Bronxville, N. Y. These circuit breakers are so constructed that each side of the circuit in the double pole type is separately closed. The instant the current flows, the side of the switch not held by the operator will automatically fly open and open the circuit if an overload or short circuit exists. If an overload occurs later, after the operator has left the switch, then both poles will open simultaneously. In both cases the circuit is instantly interrupted, and all the arcing occurs on carbon. The carbon blocks are readily replaced by loosening a couple of screws. The contact blades are detachable by removing one screw, and can be mailed in an ordinary envelope. They are of novel construction insuring perfect contact, and have a contact duty of 50 amperes of current for each square inch of blade surface. The only adjustment is that of raising or lower-



WARD LEONARD ELECTRIC CO. CIRCUIT BREAKER.

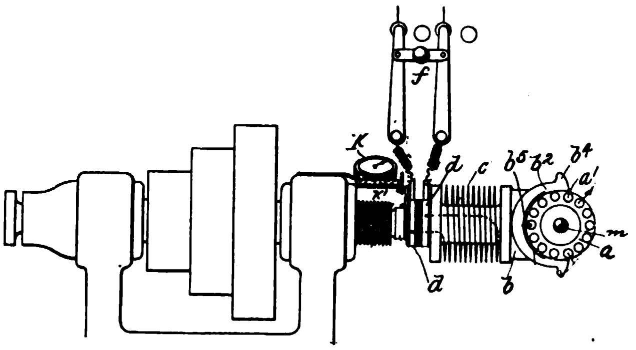
ing the vertically movable core of the solenoid magnet. The adjustment ranges from 25 per cent. under, to 50 per cent. over the current which the circuit breakers will continuously carry. The adjustment readings cover a long range of travel of the core, and are well defined and easily read. This type of circuit breaker is particularly applicable for switchboard work, as all the connections are made on the back.

A prominent electrical engineer of New York City writes in regard to this circuit breaker: "The points of superiority I have noticed are: 1st. Reliability of action; due to having the two independent automatic switches in the one instrument, one for each pole. Also the use of rolling friction in the latches. Also the strong hammer blow positively opening the switches when the latch is released and produced by energy independent of the momentum of the iron core which has merely to release the roller friction latches. 2d. Perfection of switch contact; due to the use of multiple, independent switch blades set into perfectly plane contact by independent springs. 3d. Ease of closing switch; due to closing only one pole of the switch at a

time and also due to the smooth flexible contact. 4th. Safety in closing switch which cannot be closed upon a short circuit or overload. 5th. Cheapness and simplicity of removing all working parts. 6th. Small dimensions often of great importance in switchboard design; also minimum extension from switchboard when open. 7th. Ease of tripping the switch by hand."

Oehring's Winding Device for Small Armatures.

WHAT appears to be a very ingenious device for supporting small armatures during the process of winding, is described and illustrated in a patent just granted to August J. Oehring, of Chicago, Ill. The following abstracts and brief description of the apparatus may prove of interest: Referring to the figure, which is an elevation of a head stock of a lathe with the device in position, the core of the armature to be wound is shown at a, which is constructed of laminæ of sheet iron, the holes and slots of which are aligned in assembling. This forms the longitudinal recess a' in which the armature coils are disposed. An iron chuck b is secured by a brass extension to the live spindle of a lathe, the chuck being provided with a curved jaw b^2, adapted to receive the armature core. The stem of the chuck is surrounded by magnetizing coil of wire c, the



OEHRING'S COIL WINDING DEVICE.

terminals of which are connected to two insulated collecting rings d d, with which a pair of brushes make contact. A switch f is provided, which is adapted to include a source of electricity in circuit with the brushes, rings and coil to magnetize the chuck-jaw, which is thus enabled to secure the core a in position by magnetic attraction. The face of the chuck jaw next to the core is preferably recessed.

The armature core is disposed within the chuck with opposite recesses in which a coil of wire is to be disposed placed adjacent to the lips b^4 of the chuck jaw. A lug b^5, extending from the chuck jaw is adapted to enter another of said recesses to prevent the core from rotating after it is adjusted. While the core is being inserted within the chuck, current through the magnetizing coil c should be broken. The surfaces of the lips b^4 recede from the recesses in the core and are rounded, as shown in the figure.

In winding the armature the live spindle of the lathe is rotated, the armature core being thereby revolved in a plane coincident with its shaft m. The armature wire is attached at one end to the core and is unwound from its bobbin as the core is rotated and wound within the opposite recesses in the core. The wire is held in the hand of the operator in a manner to cause its engagement with the lips of the chuck jaw which guide the wire into the adjacent recesses a'.

To insure an equal number of windings in each coil of the armature, an instrument is provided for measuring the number of rotations of the chuck and contents, which may consist of a cyclometer k, which is actuated by a roller k', mounted upon an arm, projecting from the stem of the chuck. When the cyclometer indicates the predetermined number of revolutions, the lathe-belt is shifted to stop the rotation of the chuck, the core being thereupon readjusted for the winding of the next coil.

MR. W. A. CHAMEN has been appointed city electrical engineer of Glasgow, Scotland, at an initial salary of $4,000 per year. He is 33 years of age, was with Messrs. Crompton and had charge of the construction of the electrical plant of the great Liverpool Street railway station in London.

LETTERS TO THE EDITOR

Some Practical Questions in Electric Motor Business Answered.

YOUR article in The Engineer of Jan. 6, 1898, on page 2, gives a table of the number of motor horse-power furnished by the Edison Electric Iluminating Company in Brooklyn, between Jan. 1, 1890, and Jan. 1, 1898. It seems to me that a very interesting article could be written on this one subject alone; I know that I should be much interested in it, and I believe others would.

1. Such questions as the number of motors in use for different units of power. Of course, in this I should not expect every individual unit to be separated, but that they might be separated into units such as one-half power, or less, one-half to one, one to five, etc.

2. What are the rates paid for motor service?

3. What is the actual amount of power delivered, as compared with the nominal capacity of the motors, or machines using the power.

4. Whether it is best to collect the revenue on the basis of meter rates, or a less rate on the nominal basis of power used.

5. Whether the power actually sold, if on a nominal basis, would not be much in excess of the power actually used.

6. The satisfaction, or dissatisfaction, of the users of power, as compared with power obtained from steam plants.

7. Which is the cheaper in actual cost to the consumers, steam or electric power.

8. Whether the Electric Company to obtain the power had to keep solicitors in the field, showing up the advantages and urging users to change from steam to electric power.

9. What became of the steam plants, when the electric plants were installed.

10. At whose expense was this change made?

11. What would be the diagram for the motor service, subdividing into different industries, if run at different periods of time.

These are a few of the points that occur to me.

JAMES H. HARLOW.

Wilkinsburg, Pa.

The above letter was submitted to Mr. W. S. Barstow, general manager of the Brooklyn Edison Company, who has favored us with the following reply:

On account of the large amount of work which has overtaken us in Brooklyn, I fear we shall have no time to make any special tests on motors, although we contemplate doing it some time in the future. In the meantime I might enlighten Mr. Harlow on some of his questions as follows:

1. This question is not quite clear, and I will be unable to answer it without further explanation.

2. The rates paid for motor service vary from 12c. per horse-power hour to 3c. per horse-power hour, depending on the number of horse-power hours used during the month, and on the two-rate system the hours of the day in which they are used.

3. The actual percentage of motor load to the shop rating of the motors installed is about 33⅓ per cent.; that is, with a connected load of 3,800 horse-power, representing various lines of business, etc., the actual load in the station rarely exceeds 1,200 horse-power.

4. It is no doubt preferable to collect revenue on a meter basis, as a contract system is simply guesswork and obliges the company to keep watch of the individual customers, something which is impossible in a large installation.

5. This question is not quite clear.

6. We have very few cases indeed of disconnection of power on account of dissatisfaction, as parties carefully investigate the question before purchasing the motors.

7. Whether steam or electric power is the cheapest, depends on the business and conditions under which the customer is operating. We have several cases in Brooklyn where the furnishing of steam to an engine not only costs a man nothing, but he would actually lose money if he did not consume his refuse and was obliged to cart it away.

8. It is necessary to keep solicitors in the field continually demonstrating the advantages of electric power over steam.

9. The steam plants are disposed of in some way after the electric plant is installed.

10. All expenses of changing from steam to electricity are borne by the customer.

11. As this question is not clear, I am unable to answer it.

W. S. BARSTOW, General Manager.

Brooklyn, N. Y.

Exhaust Steam Heating.

I NOTICE a brief article by W. B. Lewis on this subject in your issue of Jan. 27. As both "Le Chat" and "Sic. 'Em" seem to have retired from the field I will take the liberty of commenting upon some of the theories of Mr. Lewis. One of these seems to be that with a simple cylinder engine "the initial pressure must be increased to three or four times the back pressure in order to make the engine do the same amount of work as before." I believe this to be a fallacy. Back pressure on a plain cylinder engine is simply an increase of the weight of the atmosphere against which an engine works. When exhausting into the air it works against a pressure of nearly 15 pounds. That is the difference between the atmosphere and a vacuum. With 5 pounds back pressure, the engine works against an atmosphere of 19 pounds. No matter what the theories are, I know that in practice this rule holds good. I am familiar with several of the large exhaust plants operating under the Holly System. Mr. Lewis will not get any support for his theories from the engineers or managers of any of these plants. One plant heats 10,000,000 cubic feet of space with exhaust steam. The engines used are both compound and single expansion. With from 2 pounds to 5 pounds back pressure on their nine engines the engineer says: "We do not notice any difference in the working of our engines." The manager of another plant which runs six engines aggregating 1,000 horse power and carries 3 pounds to 5 pounds back pressure, says that by increasing the initial pressure by the same amount "the efficiency of the engines was not impaired." Another manager running six engines says "they run smoother under back pressure than without."

This seems to be the universal testimony, that an engine working under back pressure never pounds, and works smoother under a maximum load. Theory is well enough where practical results are not attainable. but must yield to facts in actual practice.

Mr. Lewis's dictum that "the only way to heat by exhaust steam is to use a vacuum system" by itself, would not be very convincing unless he is speaking from experience. The vacuum plan is made to work quite well in single buildings, but in a system where a large number of customers are served, as must be the case where the exhaust from large power stations is utilized, it would be idle to attempt it. A leak in a single service pipe. or a failure at some point not easily accessible would for the time cripple the whole plant.

I. H. B.

February 3, 1898.

LITERATURE

FIRST REPORT UPON MAGNETIC WORK IN MARYLAND, INCLUDING THE HISTORY AND OBJECTS OF MAGNETIC SURVEYS. By L. A. Bauer. Maryland Geological Survey. The Johns Hopkins Press. Baltimore, 1897.

The title of this brochure sufficiently explains its contents. and as we have already placed the main points on which it treats before our readers, it is not necessary to repeat them. Suffice it to say that this report is a model of its kind in every way, both as to literary style and typographical get-up. The magnetic maps are carefully worked out and the description of the instruments employed and their method of handling ought to be most helpful to others designing to undertake similar work. Our various State surveys have been lamentably behind in magnetic work. and Maryland has set an admirable example in this respect.

TELEPHONY AND TELEGRAPHY

Telegraph Privileges to the Federal and Western Union Lines in Mexico.

The Mexican government has published an order to the Mexican National Railroad Company, and the Mexican Central Railroad Company notifying them that they must discontinue handling commercial and other telegraph messages between the United States and Mexico, on the ground that the class of telegraphs which the railroads are entitled to establish and operate is clearly defined in Article XIV of the Regulation Law, of December 7, 1867.

The effect of the order, if fully carried out, means that the telegraph service in Mexico must be carried over the Federal lines. Under a contract between the government and the Mexican Telegraph Company, operating by cable from Galveston to Vera Cruz, and with the Western Union from Láredo and El Paso, all international telegrams will be carried by those companies.

The officials of the Postal Telegraph Company, in this city, say that their company received information some time ago to the effect that the Mexican government had entered into a contract of exclusive connection with the Western Union Telegraph Company for the exchange of. commercial telegraph business with the Federal lines of Mexico, and that the effect of this contract, if carried out, would be to prevent the railway companies, who own their telegraph lines, from transmitting commercial business, which they have contracted to exchange with the Postal Company. The Postal officials further explain that the railway companies claim that their concessions from the Mexican government as clearly confers upon them the right to transmit commercial telegraph business as to operate their railways; that the constitution of the Mexican government distinctly prevents the establishment of a monopoly within the Republic of Mexico; that the action proposed is a discrimination in favor of one corporation against another; that it is in restraint of trade, and against public policy, and that they are in communication with the Mexican government, with the view of maintaining these rights, both in the United States and in Mexico.

An Interesting Telephone Anniversary Dinner At New Haven, Conn.

The president and directors of the Southern New England Telephone Company celebrated the 20th anniversary of the opening of the first telephone exchange in the world by giving a dinner at the New Haven House, New Haven, Conn., Friday night, Jan. 28.

Among the guests were Charles F. Cutler, president of the New York Telephone Company, who was concerned in the organization of the earliest telephone companies in Massachusetts; William D. Sargent, vice-president of the New York and New Jersey Telephone Company, who was engaged in the early establishment of the Philadelphia exchange; D. I. Carson, who since 1879 has been engaged in the development of the Southern Atlantic States with the Southern Bell Telephone Company; Samuel Ivers, treasurer of the Southern Massachusetts Telephone Company, a pioneer in his locality; Thomas D. Lockwood, one of the oldest and ablest electrical experts of the American Bell Telephone Company; Gen. E. P. Meany, of New York, the man to whose efforts is largely due the extension of the long distance lines; W. J. Denver, manager of the New England Telephone Company; Joel C. Clark, Morris F. Tyler, A. L. Salt, W. N. Eastabrook, A. C. White, G. S. Pond, E. J. Pittman, C. B. Doolittle, Henry L. Storke. J. English, S. E. Merwin, E. N. Clarke, F. A. Allan, W. G. Riggs, A. F. Lincoln, J. W. Alling, H. F. Stevens, Geo. E. Betts, W. N. Sperry.

The dinner was purely a friendly affair. There were no toasts, but the development of the telephone was interestingly discussed, and a number of amusing stories were told. The menu cards were artistic and unique. On the third page was a fac simile of one of the first telephone lists issued. It contained 50 names. On the fourth was a photo fac simile of the first and only telephone bill ever paid by President Morris F. Tyler, of the Southern

New England Company. It is dated Feb. 27, 1878, and shows that he paid $9 for six months' service to the District Telephone Company.

Concessions to Canadian Telegraphers.

W. H. Allison, chairman of the Canadian Pacific Railway Telegraphers' Committee, recently in conference in Montreal with the officials of the company in reference to the annual agreement, has issued a circular reciting the concessions made by the railway company, as follows: (1) The right of trial or investigation in case of discharge or suspension. (2) Telegraphers are not to be discriminated against for serving on boards of adjustment. (3) Rights of promotion. (4) Telegraphers will be allowed to attend their annual or regular meetings. (5) No telegrapher will be required to teach the art of telegraphing. (6) Extra pay for attending switch and semaphore lamps. (7) Telegraphers will not be required to shovel snow, sift ashes, or scrub stations. (8) Commissions to be paid on commercial business. (9) Twelve consecutive hours to constitute a day's work. (10) Overtime after twelve hours. (11) Telegraphers will be exempt from Sunday work as far as possible. (12) Telegraphers in the service for four years or more will be entitled to two weeks' leave of absence each year, together with full pay. (13) Minimum salaries range from $38 to $50 a month, in some cases including dwelling, fuel, and light, and some relieving agents being allowed 50 cents per day extra for expenses. Several thousand dollars of individual increases were also secured, and the company agreed to place extra men at several points during the busy season.

MECHANICAL

Physical and Chemical Properties of Volatile Oils in Boilers[1]—II.

(Concluded.)

BY W. H. EDGAR.

NOW, why do people want to use kerosene? It is generally the man up at the office end of the institution that clings to the practice; it is generally the superintendent or the manager that clings to kerosene, because it costs nothing; he is getting something for nothing. That is where so many men have made a mistake even in the running of large enterprises and large businesses. One of the greatest dangers is to look for something for nothing. Even in the hiring of men to represent them and in the hiring of help; in the hiring of brains around their establishment, they are not willing to pay; they want ten dollars put in their hands before they will give eight dollars; a man cannot do that in business. You cannot get something for nothing, and you cannot get any man to run his business without profit. This is true of boiler compounds, which to the modern steam plant owner is far behind all other branches of science. If you will in using kerosene or using any volatile oil of that nature whatever, take the subject up and look into it for yourselves, you will find that the deleterious effects, the general carbonizing and pitting, the general eating away of that thin natural skin of the iron (the finish as it comes from the boiler maker) is a dangerous thing. It takes several years to scale a boiler to start with, on a fairly good water, but if it is scaled once it will scale again in three months, because the skin of the iron is gone. When the skin of the iron is once gone, the scaling ingredients readily attach themselves to the rougher iron, while in the new boiler they cannot adhere as rapidly as they can in the boiler where the skin is gone.

In the discussion which followed, Mr. Edgar elaborated his very interesting address by the following remarks:

Speaking of vegetable compounds, we should use sugars and tannins only and in this way as follows: We find that we can take care of the carbonates of lime and magnesia with tannin extracts and that is what we want; we do not want the extracted tannic acid. We want the tannin in the extract form and still combined and containing the inert matter, the sap, the sugar and the starch. We want that because we do not want the straight pure tannic acid. It is too stable in itself to be readily convertible into tannates. Our object is to convert carbonates of lime and magnesia into tannates. Now we find that we cannot work on gypsum, the sulphate of lime with tannin. We find that gypsum is one of the four insoluble sulphates and that it is so stable in itself that it is not even soluble in its own acid and is soluble only in the analytical laboratory in small quantities in hydrochloric acid.

We find that sugar introduced into the steam boiler with the water will convert the sulphates into saccharates. The saccharates break up into oxalates, tartrates and carbonates; and in the presence of tannin extracts, part of that goes into tannate of lime, so that we need but a small proportion of sugar present in the general mixture to handle a water containing both the sulphates and the carbonates. Your sulphates and carbonates are to be proportioned according to the percentage of the carbonate and sulphate contained in the water determined by analysis.

Under no circumstances should kerosene oil be put in the boiler. I would make the same remark in regard to caustic soda.

In answer regarding steam heaters: I think one of these steam heaters is a good thing on hard water for you get from 50 to 70 per cent. out. If a water is so soft that you get all the impurities out, it becomes too pure and you pit your boilers. Water is a great solvent. In the East where the soil is principally granitiç there is very little scale, only about two or three grains to the gallon; but throughout the West, where there is a limestone soil, you get from 16 to 40 grains.

A surface blow-off contrivance is very good, but the trouble is, they are expected to do all the work and sufficient interest and care is not usually taken in the application of such contrivances. The boiler is too often neglected and it cannot get up and speak its piece like the engine, when anything is wrong. You must diagnose your case and work out your own ideas.

Do not forget to treat the boiler regularly. Put in whatever you use, regularly. Have the water analyzed and go to the wholesale druggist and he can mix up the tannins and sugars in proper proportions, but do not use any soda. Some sulphate waters require considerable starch, slippery elm, etc.; they sometimes use five or six per cent. of carbonate of soda in boiling it together which kills the gelatinous properties, and then when you introduce your tannin extract, the carbonate is converted into tannate of soda; five per cent. tannate of soda, 20 per cent. of sugar and 50 per cent. of tannins. The steam users in the country should look into this thing and should study their boilers. There is an article on the impropriety of the use of caustic soda, in the October issue of the National Engineer. Also on "Water," in the December issue.

The greatest point in regard to compounds is the care given to the boiler.

You should get the engineer interested in the matter.

[1]Abstract of an address before the Northwestern Electrical Convention, Milwaukee, Wis., January 20, 1898.

PERSONAL

Tyndall's Bequest to the Royal Institution.

Mrs. Tyndall, the widow of Prof. Tyndall, according to "Nature," has sent the following letter to Sir James Crichton-Browne, F. R. S., the treasurer of the Royal Institution: "Dear Sir James:—As an expression of his attachment to the Institution, with which he was so long connected, and of his sympathy with its objects, my dear husband desired me (at such time as should be most convenient to myself) to present in his name to the Royal Institution £1,000 ($5,000), to be disposed of as the Board of Managers may see fit for the promotion of science. I have now the pleasure of remitting to you this sum. Yours faithfully, Louisa C. Tyndall." Sir James Crichton-Browne, in the course of his letter acknowledging this generous donation, remarks: "The managers would, I am sure, desire to be guided by any wish of yours as to the application of the gift; but, in the absence of any explicit directions, they will, I have no doubt, employ it in the promotion of that original scientific research in which your husband's vivid and penetrating intellect delighted to exercise itself. Revered as your late husband's memory is,

and ever must be, in the Royal Institution, this posthumous mark of his solicitude for its welfare will, if possible, deepen the affectionate esteem in which he is held."

MR. N. W. PERRY, of Westinghouse, Church, Kerr & Co., has, we regret deeply to hear, been ordered by his doctors to abstain from work for awhile in order that his health may improve. It is to be hoped that he may soon again be in shape to resume active work.

SOCIETY & CLUB NOTES

Important Meeting of the New York Electrical Society.

A very interesting meeting of the New York Electrical Society will be held at the College of the City of New York at 8 P. M. on Friday, Feb. 11, when papers will be presented by Mr. Joseph Wetzler on "Electricity Direct From Coal," and by Prof. George F. Barker and Dr. Edgar Smith on "Important Aspects of Electro-Chemistry." The meeting will be a joint one with the New York section of the American Chemical Society.

Webster Lecture Before the Röntgen Society.

BEFORE the Röntgen Society, on Tuesday evening, Jan. 11, under the presidency of Prof. Silvanus Thompson, a paper was read by Mr. W. Webster, F.C.S., on "Practical Work with the X-rays." He first dealt with the question of the best apparatus to use, and pointed out the value of primary batteries. Mr. Webster then pointed out how much had been done by Sir William Crookes and Mr. Jackson, and remarked that Dr. Röntgen had merely put the finishing touch to their discoveries. He showed the tube which had been made by Mr. Jackson in 1894, with which he had demonstrated that wood and other materials were pervious to certain rays. He had found an improvement to prevent the spark from passing round the bowl of the tube, and thus lessening the danger of perforation. By heating the tube and starting with a small spark he was able gradually to produce the effect he wished, and had thereby saved the lives of many tubes. The bulb of the tube should not be very large, as the larger it was the more difficult the tube was to condition, and the greater were the number of accidents. An aluminum cover for the cathode tube was an advantage, and a protector of sheet iron was useful for saving the hands from the effect of the rays. The effect of the rays varied very much with different subjects. In the case of one patient, whose head was photographed, a patch of his hair first turned gray and then came out, and he was not grateful to the rays; however, the hair had grown again afterwards of the original color. In other cases, however, the pain in the injured or diseased part had entirely ceased after five or six minutes' exposure to the rays. Anæmic subjects were the best to photograph, while gouty subjects were particularly difficult. To produce good negatives, considerable experience in photographic development was necessary, especially in the production of cloud negatives.

MARRIED

Dallas—Desvignes.

The marriage is announced in London of Mr. James Douglas Dallas, of Egerton Gardens, S. W., to Antoinette Charlotte, daughter of Commander Doré D. Desvignes, of Milan, Italy, and his wife, née de Valcourt. Mr. Dallas was at one time engaged in electrical engineering work in the United States, making many friends who will wish him all prosperity in his new relationships and in his professional work at home in England.

REPORTS OF COMPANIES

Stanley Electric Manufacturing Company.

The annual meeting of the Stanley Electric Manufacturing Company, of Pittsfield, was held January 25, 1898, and the reports were gratifying. The business of the past year has been very prosperous, and for a good part of the time their extensive shops have been run overtime. The shipments show a decided increase over last year, or about 12½ per cent., and more orders to begin the new year with than they have ever had before. The gross profits for the year are reported at over $100,000. A dividend of 6 per cent. was declared, payable April 1, to stockholders of record January 25. The stock is quoted at 130. Pittsfield is pleased with the prosperous company in its midst doing a business the past year of about $600,000. The old officers were elected as follows: President, W. W. Gamwell; treasurer, George W. Bailey; general manager, John H. Kelman; general superintendent, Henry Hine; electricians, C. C. Chesney and John F. Kelly; directors, William F. Gamwell, William A. Whittlesey, William R. Plunkett, Walter F. Hawkins, Henry Hine, George H. Tucker and George W. Bailey. The company's machines are in active demand, going to foreign countries, including Japan, and four large ones were shipped to California yesterday. The company also maintains a large shop in Canada for English and Canadian trade.

Annual Report of the New York Edison Ill. Co.

WE give below an abstract of the interesting and important annual report of the New York Edison Company, as made by First Vice-President R. R. Bowker. The figures are also considered editorially this week:

This company, which first sold current in 1882, had on January 1, 1890, 1,200 customers and installations of 39,815 incandescent and 77 arc lamps and 421 horse power in motors, being the equivalent of 46,900 16-candle-power lamps. Its maximum output was 12,000 amperes (estimated); it had $2,850,000 loan and share capital; its gross income for the previous year was $329,773 and its net $124,031 or 38 per cent. After eight years of development, it has now (January 1, 1898) 7,313 Edison customers, and installations of 346,723 incandescent and 4,775 arc lamps and 19,364 horse power in motors, being the equivalent of 696,370 16-candle-power incandescent lamps, exclusive of 60,068 high-tension and 80,928 breakdown connection, equivalent in all to 837,366 16 candle power. It reached, in 1897, 100,000 amperes maximum output; it has $14,500,000, in round numbers, loan and share capital; its gross income for combined systems was, in 1897, $2,486,636, and its net, without depreciation charges, $1,261,497, or 50.7 per cent., or deducting depreciation charges, $1,117,497, or 45 per cent. The progress in eight years shows six times the number of customers, seventeen times the installation, eight times the maximum output, on but fivefold the capital, with over seven times the gross and nine times the net income. In the eight years no previous year has shown so great an increase as 1897, in which the number of customers has been increased 751, the number of Edison lamps 67,318, the number of arc lights 1,550, the horse power in motors 3,433, and the installation equivalent 136,028. For the Edison system only the gross station returns have increased 13.7 per cent., and the general and operating expenses have increased 10.9 per cent. It is especially remarkable that this development has taken place with so small an increase in the investment account, the extensions of the system having been confined during the present year to additions to the generating plant requisite to maintain the proper reserve, the extension of the feeder system to points where was indicated increasing demand, and the extension of the mains only to points where that demand was definitely promised.

The following table shows the net increase in the several classes of installation and in earnings in the past year, reckoning a standard arc lamp as the equivalent of ten 16-candle-power incandescent lamps and a horse power in motors as the equivalent of fifteen 16-candle-power incandescent lamps, the basis

agreed upon by the leading Edison companies for reckoning such equivalents:

	1897. Dec. 31.	1896. Dec. 31.	Increase in one year.	Perct. Inc.
No. customers	7,313	6,562	751	11½
No. inc. lamps	346,723	279,405	67,318	24
No. arc lights	4,775	3,225	1,550	48
No. motors, h. p.	19,364	15,930	3 433	21½
Total equiv. 16 c. p.	696,370	560,342	136.028	24⅓
Gross station returns †	$2,015,102 09	$1,771,229.83	$243,872.26	13¾
Gen. and oper. expenses*	929,263.87	836,396.77	92,867.10	11
Net station returns †	1,085,838 22	934.833.02	151,005.16	16
Prop. expense* to gross†	46%	47%		

*Exclusive of depreciation charges. †Not including outside earnings.

The figures include only Edison central station direct service.

The following table gives the figures inclusive both of Edison central station service and of isolated plant installations supplied from the Edison stations during minimum hours or for emergencies:

	Central Station Service.	Isolated Plant Service.	Total Service.
Customers	7,313	74	7,387
Meters	9,826	115	9,941
Incandescent lamps	346,723	56,341	403,074
Inc. lamps, 16 c. p. equiv	354,740	59,578	414,318
Arc lamps, number	4,775	692	5,467
Arc lamps, 8 ampere equiv	5,117	692	5,809
Motors, h. p. equiv*	19,364	962	20,326
Total equivalent	696.370	80,928	777,298

*Miscellaneous equipments, such as heaters, organ control, physicians' apparatus, etc., are included in h. p.

The isolated plant service or emergency connections show lower figures this year, in part because a number of isolated plants have been shut down and are now taking central station service.

These figures do not include those of the high-tension companies operated under the supervision of this company and constituting practically the high-tension division of this company. These companies had on their station service December 31, 1897, 35,568 incandescent and 2,426 arc lights, and 16 horse power in motors, or an equivalent of 60,068 16-candle-power, which, added to the Edison station service, gives a total of 756,438, or, with isolated plant service, 837,366 16-candle-power equivalent.

The equipment at the Duane Street Station was increased during 1897 by the addition of one B. & W. 553-horse-power boiler, one Southwark 2,500-horse-power quadruple expansion engine, and two General Electric 800-kilowatt dynamos, making the total equipment at the Duane Street Station at this date, in boilers, 5,050 (rated) horse power; engines, 11,800 horse power and dynamos, 7,600 kilowatt.

The Bowling Green Storage Battery Annex, supplementing the Duane Street Station, has a storage battery capacity of 8,000 ampere hours at a ten-hour discharge rate, or 4,000 amperes at 125 volts for one hour.

The equipment at the 12th Street Station was increased during 1897 by one B. & W. 333-horse-power boiler, one McIntosh & Seymour 1,250-horse-power triple expansion engine, and two General Electric 400-kilowatt dynamos, making the total equipment at the 12th Street Station at this date, in boilers, 1,332 (rated) horse power; engines, 2,500 horse power; dynamos, 1,700 kilowatt, and a storage battery, with a capacity of 8,000 ampere hours at a ten-hour discharge rate, of 4,000 amperes at 125 volts for one hour.

At the 26th Street Station, two McIntosh & Seymour 250-horse-power engines and four 100-kilowatt dynamos were replaced by one Southwark 1,250 horse-power cross-compound engine and two General Electric 450-kilowatt dynamos. Its equipment at this date is, in boilers, 2,576 (rated) horse power; engines, 4,550 horse power, and dynamos, 3,300 kilowatt.

The 39th Street Station maintained its previous equipment, its capacity being as last year, 1,630 (rated) horse power, in boilers; engines, 2,400 horse power, and dynamos, 1,840 kilowatt.

At the 53d Street Station, one N. Y. S. 200-horse-power engine driving one 60-kilowatt and one 100-kilowatt dynamos were replaced by one McIntosh & Seymour 250-horse-power engine, and. two 100-kilowatt dynamos, transferred from 26th street. The equipment consists of, boilers, 1,123 (rated) horse power; engines, 1,300 horse power; dynamos, 1,080 kilowatt; and a storage battery, having a capacity of 2,600 ampere hours at a ten-hour rate.

The 72d Street Annex Station is supplied by the Manhattan Company from its main station at the foot of 80th street, with high tension current, operating a 240-kilowatt motor at 2,000 volts, which drives two 100-kilowatt Edison 135-volt direct-current dynamos.

The mileage of the underground street system December 31, 1896, was, on the 3-wire system, 70.67 miles of feeders and 138.49 miles of mains, a total of 209.16 miles of the 3-wire system; and on the 2-wire system, 0.17 mile of mains. The total mileage December 31, 1896, including 2.43 miles of cable feeders, was 209.33 miles of mains and feeders. The system also included December 31, 1896, 1,208 junction boxes at intersections.

During the year 1897, in the downtown district, 3.29 miles of 3-wire feeders have been laid, and 0.53 removed, an increase of 2.76; and 2.93 miles of mains have been laid, and 0.81 mile removed, making an increase of 2.12 miles. Of the old 2-wire system in the downtown district 0.02 mile of mains has been removed. This leaves but 0.15 mile of mains of the old 2-wire system. The net increase in the first district is 4.86 miles.

In the uptown district 5.04 miles of feeders have been laid and 1.32 removed and 4.85 miles of mains laid and 0.97 removed making an increase of feeders of 3.72 miles and in mains of 3.88 miles, a net increase of 7.60 miles, all 3-wire, in the second district. The removal of feeders and mains uptown was chiefly due to replacement with larger conductors of the small tubing used in some streets when the uptown system was first laid.

The greater part of the feeder system laid during the year consisted of cable feeders, of which there were 2.83 miles laid in the downtown district and 4.22 miles in the uptown district, and none removed; making a total increase of 7.05 miles. As there was a total decrease of 0.57 mile of tube feeders, the net increase in the feeders of both districts amounted to 6.48 miles.

The net increase of the system, in both districts, is 12.46 miles, bringing the grand total December 31, 1897, to 221.79 miles. The increase in junction boxes has been 42, making a total of 1,250.

The number of service connections added during the year was (net) 377 in the downtown district, and 567 in the uptown district; in both 944.

The Inspection Department has continued its successful work, combining as hitherto the functions of the general agency with those of general inspection. During the year 235 contractors have reported installations, involving 3,265 reports. Of these, 18 have reported installations reaching over 1,000 incandescent lamps in the year past. Of electric motors, which have continued to show marked development, 58 types have been installed on the system, numbering 1,574 motors, averaging 3 horse power each and aggregating 4,737¾ horse power. The special development of the year has, however been in the increase of enclosed arc lamps, of which 1,633 have been added in 1897 to the system. The figures represent the total additions, without deducting changes and withdrawals.

The Meter Bureau, under the general charge of the Controller, has continued its excellent efficiency during the year; it had under its care on December 31, 1897, 9,941 meters, of which 6,744 were Edison chemical meters and 3,197 mechanical meters. The usual careful attention has been given to complaints from customers, as to amount of bills, etc., of which 1,530 were received during the year. In connection with these complaints there were found 215 errors, of which 138 were clerical and 77 technical. The proportion of errors to bills rendered was 1 in 511, or less than ⅕ of 1 per cent., an increase of proportion above that of 1896, due in large measure to the extensive change from chemical to mechanical meters, involving a considerable strain on the Meter Bureau. There is reason to hope that the proportion will be considerably reduced in another year. The company continues its policy of offering to submit any disputed case to arbiters, and in general has succeeded in showing to customers its desire to treat every one with entire fairness.

The report then discusses at length the reduction of rates which is noted editorially in The Electrical Engineer this week.

The development of the enclosed arc lamp has not only led to a great extension of the low-tension arc light service, which shows an increase from 3,225 to 4,775 in 1897, but has made possible a remarkable development of low-tension street lighting. After a careful collation of views and plans of arc lamp posts used in various cities here and abroad, the Engineering Department designed a new form of post, for city lighting, of artistic pattern, which has met with general approval. This post bears on its base the arms of the city and the seal of the Edison Company, and is surmounted by a graceful curve in place of

the awkward yard arm, and a view of it, as also of the latest pattern of the twin-lamp post used on Fifth and Madison avenues, is given with this report. These enclosed arc lamps burn approximately 100 hours without retrimming, permitting a considerable saving in both carbons and labor, so that the same price could be made to the city as for high-tension street lamps, namely, 40 cents per night, which averages less than 4 cents per hour of service. Of these lamps 236 have been installed in the streets during the past year, and 300 more are included in the plans for city lighting for the coming year. The company has undertaken the lighting of the Seventh and Ninth Regiment Armories, and of other city buildings, with incandescent lamps, and it is expected that other public edifices will hereafter be lighted by electricity instead of gas.

The relations with employés have continued to be thoroughly satisfactory. The Labor Benefit Fund, now put on a definite and permanent basis, has not only provided for the payment of benefits to employés, ranging from 4 per cent. on the annual salary or wages, to those in the employ of the company for ten years, to 1 per cent. to those of one year's service, but has permitted a wise liberality on the part of the company in cases of fatal or disabling accidents, where no legal technicality was involved.

It is the practice of the company to give careful attention, in a systematic manner, to the salaries and wages of each person in the company's employ, regularly before the opening of each fiscal year, and also semi-annually and quarterly as occasion required. All questions of salaries and wages are brought before the executive in careful reports from the respective heads of departments or superintendents, showing the length of service of the employé, his original remuneration, his last increase of pay and the proposed increase, and these recommendations are made the subject of careful comparison, not only with the compensation given in similar positions in the several departments of the company, but with the rates of salary or wages prevailing outside the company. Thus the employés feel assured that their services are fairly considered, and the question of their pay regularly brought to attention, without effort or appeal on their part, and this method of handling rates of pay has helped to bring about the present satisfactory relations between the company and its employés.

The use of electricity for heating and cooking has shown some, though not great development, and it is hoped that reductions of rates will stimulate this use. The electrical kitchen in the company's building in Duane street, from which the Friday staff luncheon is always served, has been a useful object-lesson of the simplicity and convenience of cooking by electricity, and an illustration showing the neatness and compactness of this method, is given with this report. The use of electric carriages, carrying storage batteries which are charged from this company's system, has become a part of the public cab service in New York, and the company is planning for supply connections in the street, with automatic meters, which may permit more general use of electric vehicles.

The officers and superintendents of the company have rendered most efficient service during the year, as is evidenced by the satisfactory results of the company's business. It is my great satisfaction to acknowledge that these results have been reached, by the co-operation of the employés in the humblest posts, each in his measure, as fully as by that of the most important officer. The company's development has steadily outrun the estimates of growth, and it is evident that the 1,000,000 16-candle-power equivalent installation point will be reached by 1900. In view of this phenomenal growth, the company's engineers have for the past year again been giving most careful attention to the problems of the future, and are reaching results and working out plans for the new century which will doubtless commend themselves to the judgment of those most concerned, when they are ready for publication.

MR. GUSTAV BISSING, principal examiner in the U. S. Patent Office, Electrical Division A, has resigned and has entered into partnership with Mr. Joseph Lyons, the well-known mechanical and electrical expert and patent solicitor, of Washington, D. C. The firm will continue to engage in the practice of patent law in all its branches. Its new offices will be situated in the McGill Building, 908 G street, N. W., Washington, D. C.

INVENTORS' RECORD

Classified Digest of U. S. Electrical Patents issued January 18, 1898.

Alarms and Signals:—

ELECTRIC LOCK AND SYSTEM OF ELECTRIC LOCKING FOR SECURING ADDITIONAL SAFETY IN RAILROAD SIGNALING. J. F. W. Morris & G. Mumford, London Eng., 597,650. Filed Oct. 16, 1896. Enables the signal to be put to "danger" and when the train has been examined the signal can be lowered to allow it to proceed and without giving power to clear the road until the train has been properly disposed of.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. A. Mougin, Paris, France, 597,424. Filed Feb. 13, 1897. Feed mechanism adapted with slight modification to continuous and alternating current arc lamps.

FILAMENT FOR INCANDESCENT LAMPS. F. E. W. Bowen, London, England, 597,492. Filed Aug. 17, 1897. The borate of a refractory metal is incorporated in the body of the filament.

ELECTRIC ARC LAMP. E. Blaser, California, Mo., 597,601. Filed July 15, 1897. Embodies an expansion-wire casing, consisting of two longitudinally-split tubes, one arranged within the other with the outer tube turnable on and adapted to close the inner tube, and perforated insulating-blocks in the inner tube.

Miscellaneous:—

ELECTRIC FURNACE. T. L. Willson, New York, 597,476. Filed Nov. 15, 1895. Designed for such electro-metallurgical reductions as calcium carbid.

APPARATUS FOR PRODUCING OZONE OR OZONIZED AIR. A. Verley, Paris, France, 597,517. Filed Feb. 17, 1897. Comprises two flat horizontally disposed plates arranged face to face with a small space between and constituting the electrodes, and means for projecting jets of compressed air against the upper surface of the upper plate.

REFRIGERATING APPARATUS. W. F. Singer, New York, 597,532. Filed April 5, 1897. Comprises a gas pump, the rotor of an electric motor connected thereto, a hermetically sealed casing inclosing the pump and rotor, and the stator of the motor located exterior to the casing.

MACHINE FOR ASSORTING CARBONS. H. S. Hart, Chicago, Ill., 597,646. Filed Aug. 2, 1897. Comprises a table and means for rolling the carbons over the table in combination with devices for gaging the imperfections of the carbons and ejectors controlled by the gaging devices.

Railways and Appliances:—

ELECTRIC CAR BRAKE. C. F. De Redon, New York, 597,432. Filed Sept. 22, 1896. Stationary electromagnets at opposite sides of the car, pivoted brake arms at the ends of the electromagnets, and air-brakes pivotally secured to arms and held normally upward by means of springs.

ELECTROMAGNETIC RAILWAY CAR BRAKE. C. F. De Redon, New York, 597,433. Filed April 22, 1897. The brake mechanism is in duplicate, one set being at each side of and connected to the car frame.

TROLLEY CAR. J. D. Hull, New York, 597,467. Filed Feb. 1, 1897. Automatic reel for trolley ropes designed to maintain the proper tension.

CONDUIT FOR ELECTRIC RAILWAYS. C. V. Osborn, Dayton, Ohio, 597,508. Filed July 18, 1896. Consists of two side walls bolted together, brackets limiting the width of the conduit and supporting the surface plates.

ELECTRIC TROLLEY DEVICE. G. Valley, Johnstown, Pa., 597,516. Filed March 8, 1897. Comprises a fixed and a movable base having registering recesses, a key mounted on a shaft and adapted to engage the recesses, and a trigger fastened to the shaft adapted to engage the trolley arm when in a given position.

TROLLEY WHEEL. H. B. Sawyer, Chicago, Ill., 597,693. Filed June 19, 1897. Consists of the elongated hollow body having centrally and inwardly directed end grooves.

Regulation:—

REGULATION OF DYNAMO ELECTRIC MACHINERY. F. A. Johnson, Binghamton, N. Y., 597,418. Filed April 1, 1897. Consists in varying the total flux through the armature, to vary the speed of the motor, and maintaining at all speeds a strong field at those portions of the pole-pieces under which the commutation takes place.

REGULATION OF DYNAMO ELECTRIC MACHINERY. F. A. Johnson, Binghamton, N. Y., 597,419. Filed April 24, 1897. Similar to above.

Switches, Cut-Outs, Rheostats, Etc.:—

RHEOSTAT. M. Norden, New York, 597,470. Filed April 12, 1897. Combines with two or more rheostats having contacts in circles, of arms and concentric shafts carrying such arms, a switchboard through which the concentric shafts pass and hand-wheels upon the outer ends of the shafts for adjusting the contact arms.

ELECTRIC SWITCH. E. M. French, Stoughton, Mass., 597,642. Filed Sept. 16, 1897. Means whereby the illuminating devices in the main line circuit may be controlled by push-buttons in a local battery circuit, without carrying the heavy main line wires into a building.

CIRCUIT BREAKER. F. C. Robertson, Toronto, Canada, 597,700. Filed July 22, 1895. Adapted to any telegraph, telephone or similar low-voltage electric circuit.

Telegraphy:—

SIGNAL-TELEGRAPH. C. V. Boughton, Buffalo, N. Y., 597,536. Filed Dec. 19, 1895. Consists of two series of lamps of different colors secured alternately upon a shaft, the lamps of one color representing dots and the lamps of the other color representing dashes.

TELEGRAPHIC SIGNAL. J. Nicolson, Buenos Ayres, Argentina, 597,587. Filed Feb. 26, 1897. Telegraph signals, having an uneven number of elementary motions for the vowels and accented vowels of the alphabet, and an even number of such motions for the consonants of the alphabet.

KEYBOARD TELEGRAPHIC TRANSMITTER. S. Price, Paterson, N. J., 597,689. Filed June 17, 1897. Details of construction.

Telephones:—

COIN CONTROLLED APPARATUS FOR TELEPHONES. W. Gray, Hartford, Conn., 597,556. Filed December 20, 1889. Comprises a signal device located adjacent to the transmitter, a sound deflector leading from the signal box to the transmitter, a spring lock tumbler, a coin controlled signal rod normally locked, and the signal sounding mechanism.

Classified Digest of U. S. Electrical Patents Issued January 25, 1898.

Alarms and Signals:—

ELECTRIC SIGNALING DEVICE. E. A. Stout, Jr., Philadelphia, Pa., 598,033. Filed March 23, 1897. Comprises a plurality of contact points, a combined push button and indicator carrying a contact arm which may be rotated to make contact with the different plates.

ELECTRIC BURGLAR ALARM SYSTEM. C. Coleman, Chicago, Ill., 598,049. Filed December 14, 1896. Details of construction.

DEVICE FOR PREVENTING ACCIDENTS ON RAILROADS. H. Biermann, Breslau, Germany, 598,062. Filed April 6, 1896. Means to actuate by electricity the alarm and safety apparatuses of the train when a rail has broken or a fish-plate is loosened before the train has reached the defective spot.

ELECTRIC BURGLAR ALARM SYSTEM. C. Coleman, Chicago, Ill., 598,063. Filed December 14, 1896. Details of construction.

Batteries, Secondary:—

MANUFACTURE OF STORAGE BATTERY GRIDS. W. W. Griscom, Haverford, Pa., deceased, D. I. H. Griscom, executrix, 597,846. Filed November 22, 1895. Comprises a stationary mold, a ladle and connections between the mold and ladle, permitting the ladle to be moved above and below the plane of the mold.

Conductors, Conduits and Insulators:—

ELECTRIC CABLE. W. S. Smith and W. P. Granville, London, Eng., 597,790. Filed November 1, 1897. Composed of a tubular case enclosing a cylinder which is built up of two or more segments, and has a longitudinal central hollow air space and also has one or more wires embedded in each segment, such segments being twisted as they are brought together and before the outer covering is formed around them.

Electro-Metallurgy:—

ART OF OBTAINING GOLD AND SILVER FROM AURIFEROUS AND ARGENTIFEROUS MATERIALS. N. S. Keith, Chester, Eng., 597,820. Filed February 21, 1895. Consists in first dissolving the metal in a solution containing cyanid of mercury and then passing a current of electricity through the solution to a metallic cathode.

Lamps and Appurtenances:—

LIGHT RETRACTING AND MAGNIFYING ENVELOPE FOR INCANDESCENT LAMPS. F. W. Dunlap and J. R. Quainm, London, Eng., 597,964. Filed June 2, 1897. Comprises a light refracting envelope formed of a closely wound spiral of glass rod of circular or other section applied upon the bulb of the lamp.

Measurement:—

ELECTRIC METER. G. Kapp, Berlin, Germany, 597,985. Filed Nov. 19, 1897. Comprises a supplemental apparatus for permitting the consumption of energy to be metered or charged for at different rates for different hours of the day, and means for throwing the same into and out of operation.

Miscellaneous:—

TARGET. T. Wrench, Metuchen, N. J., 597,795. Filed March 15, 1897. Operates to instantly indicate the score at any desired point away from the target proper.

ARMATURE WINDING MACHINE. C. Eickemeyer, Yonkers, N. Y., 597,816. Filed October 30, 1897. Combines with four coiling plates, and screws for actuating them, a gauge plate appropriately inscribed according to the various coils desired and traversed by a pointer carried by one of the plates.

ELECTRIC FURNACE. W. S. Horry, Sault Ste Marie, Mich., 597,880. Filed April 16, 1897. Comprises a bottomless hopper, electrodes supported on its walls, circuit connections for the electrodes, a rotatable receptacle arranged below the hopper, and plates removably applied to the periphery of the receptacle.

ELECTRICALLY ACTUATED LOCK FOR BICYCLE RACKS. F. V. Walstrom and J. Erickson, Chicago, Ill., 597,891. Filed November 9, 1896. Comprises a locking mechanism, an alarm mechanism, a relay arranged to control the alarm mechanism, and a normally closed electric circuit arranged to control the relay.

ELECTRIC FURNACE. C. S. Bradley, Avon, N. Y., 597,945. Filed December 13, 1896. Comprises a rotary annulus carrying on its periphery a receptacle for a charge, the receptacle having sectional walls permitting it to be opened and electric connections with the inside of the receptacle.

Railways and Appliances:—

ELECTRIC RAILWAY. E. C. Crocker, Bridgeport, Conn., 597,799. Filed April 23, 1897. Third rail system.

TROLLEY. G. A. Hall, Portland, Me., 597,848. Filed February 6, 1897. The roller stock is pivotally supported on the head of the pole.

SYSTEM OF ELECTRIC DISTRIBUTION. H. Linton, Altoona, Pa., 597,855. Filed May 7, 1894. Sectional underground system for railways.

RAIL CONNECTOR. J. Bryan, Pittsburg, Pa., 597,949. Filed June 12, 1897. Comprises a series of metal plates arranged approximately parallel with the rail, but separated from each other, and metal blocks adapted to be secured to the rails, a portion of the metal of the blocks intercalating with the metal plates.

Roentgen Rays:—

APPARATUS FOR MAKING OBSERVATIONS BY MEANS OF ROENTGEN OR X-RAYS. J. Wertheimer, Paris, France, 597,753. Filed July 27, 1897. Comprises two vertical casings between which the object to be examined is placed, one casing containing a vacuum-bulb, and the other a fluorescent screen.

Switches, Cut-Outs, Etc:—

SAFETY FUSE. L. A. Ferguson, Evanston, Ill., 597,969. Filed May 24, 1897. A fuse having broad ends to engage the conductor terminals, the ends being connected by an arch, a small portion of the length of which is contracted to constitute the point at which the rupture of the fuse will occur.

ELECTRIC SWITCH. J. L. Hinds, Syracuse, N. Y., 597,979. Filed February 1, 1896. Comprises a base to which the switch terminals are secured, a blade for closing the circuit between the terminals, and a backing of a slotted tube to which the blade is removably secured.

ELECTRIC SWITCH. J. R. Newell, Titusville, Pa., 597,001. Filed September 15, 1897. Push button switch. Details of construction.

Telegraphs:—

TELEPHONIC INSTALLATION. G. Ritter, Stuttgart, Germany, 597,782. Filed June 11, 1896. Multiple switchboard system for telephone exchanges.

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 597,785. Filed April 16, 1895. A relay in the line circuit controls a subsidiary signal in a local circuit.

TELEPHONE CIRCUIT. C. E. Scribner, Chicago, Ill., 597,786. Filed December 18, 1896. Means for supplying current for transmitting telephones at sub-stations from a centrally located source of energy.

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 597,787. Filed December 18, 1896. Means for automatically controlling line signals through the agency of the station apparatus of the line and for causing the effacement of the signal in the establishment of the required connection.

Construction Work at the Exhibition.

It was announced last week that the post of Consulting Engineer to the Electrical Exhibition had been accepted by Prof. F. B. Crocker, of the Department of Electrical Engineering, at Columbia University. We are now glad to note that the position of Construction Engineer has been assigned by the management to Max Osterberg, E. E., A. M., of the engineering firm of Osterberg & Sutton. This gentleman has already taken up his new duties in consultation with Prof. Crocker, and is preparing plans, etc., for the elaborate wiring, distribution and general construction required by so large a show as that for next May has already become. Mr. Osterberg made a distinct success by his work at the Exhibition of 1896, and now takes hold with greater energy and enthusiasm than ever.

A Personal Exhibit By Prof. S. H. Short.

In addition to the superb exhibit which will be made of all its modern apparatus for the generation and use of electricity, by the Walker Company, of Cleveland, Prof. S. H. Short, its electrical engineer, well known as one of the most distinguished and successful pioneers in the electric railway field, will make a personal exhibit. For some 15 years past, Prof. Short has been actively engaged in railway design and invention, and as far back as 1885 organized a company in Denver which laid and operated a slotted conduit railway. His work will now be interestingly and richly illustrated by pictures, relics, models, old apparatus, etc., and will constitute one of the features of the show that will attract wide attention and help secure for Prof. Short, the recognition which certainly is his due.

Law Against Theft of Current in Georgia.

WE give below full text of a bill for the protection of electric lighting companies, which has just been passed by the General Assembly of Georgia:

A Bill to be entitled, An Act to protect Companies engaged in the manufacture of electricity in this State for lighting or power purposes, in the use of apparatus employed in generating, transmitting, measuring or using the same, to prevent persons from unlawfully diverting and using such electric current, to prescribe a penalty for the violation of the provisions of said Act, and for other purposes.

Section 1. Be it enacted by the General Assembly of the State of Georgia, and it is hereby enacted by the same, that whoever unlawfully and intentionally injures or destroys or permits to be injured or destroyed, any meter, pipe, conduit, wire, line, post, lamp, or other apparatus belonging to a company engaged in the manufacture or sale of electricity for light-

ing or power purposes, or unlawfully and intentionally prevents an electric current from fully registering the quantity of electricity supplied, or in any way interferes with its proper action or just registration, or, without the consent of such company unlawfully and intentionally diverts any electric current from any wire of such company, or otherwise unlawfully and intentionally uses or causes to be used without the consent of such company, any electricity manufactured or distributed by such company, shall, for every such offense be punished by a fine not exceeding $100 or imprisonment not exceeding one year, or by both such fine and imprisonment.

Section 2. Be it further enacted, that all laws and parts of laws in conflict with this Act be and the same are hereby repealed.

Decision of the U. S. Circuit Court for the Southern Div. N. Y. Sustaining the Van Depoele Trolley Patent.

United States Circuit Court, Southern District of New York. Thomson-Houston Electric Company vs. Union Railway Company.

Motion for preliminary injunction under claims 2 and 4 of the Van Depoele patent No. 495,443. Lacombe, Circuit Judge.

The circumstance that these two claims were not expressly declared upon, in the Winchester avenue case divided by Judge Townsend (71 F. R. 192) is not controlling. In Westinghouse Air Brake Company vs. N. Y. Air Brake Company, 65 F. R. a preliminary injunction was granted by this court on patent No. 360,070, although it had not been previously adjudicated, on the ground that in the earlier litigation it had been "discussed at great length and its meritoriousness clearly recognized." And that injunction was sustained in the Court of Appeals (69 F. R. 715).

It is perfectly plain from an examination of the opinion of Judge Townsend and the voluminous record upon which it was based that the very combination covered by claims 2 and 4, viz., the overhead conductor and the trailing arm hinged and pivoted to the car so as to bridge the space between it and the conductor, with a contact device at its upper end, capable of being pressed upwardly into engagement with the conductor, was fully considered by him and held to be a most meritorious invention, and Van Depoele its inventor. It is thought that the decision of the Court of Appeals in this Circuit in the Hoosick Railway Case (82 F. R. 461) has not affected the weight of the Winchester avenue decision so far as it deals with the questions of invention and priority. The Court of Appeals held that claims 6, 7, 8, 12 and 16 of the patent here sued on were invalid because the particular combination or combinations which those claims covered had been already patented by Van Depoele in his earlier patent No. 424,695. And this was all that it held. The complainant therefore comes into this court with the presumption arising from those judicial conclusions in the Winchester avenue case, which the Court of Appeals did not disturb.

The two claims now declared on are as follows:

"2. The combination of a car, an overhead conductor above the car, a contact device making underneath contact with the conductor and an arm carried by the car and carrying the contact device, and pivoted so as to swing freely around a vertical axis."

"4. The combination of a car, an overhead conductor above the car, a contact device making underneath contact with the conductor, and an arm on the car movable on both a vertical and a transverse axis and carrying the contact device."

In the Hoosick Railway Case double patenting was found, because each of the claims therein considered contained in some form of words a reference to a "spring" or "weight" or "weighted spring" or "torsion spring" or "spring device," one of whose two functions was to centralize the depressed end of the trolley, and the other was to give the upward pressure to the contact end.

The two claims above quoted contain no words which can be tortured into any such reference. Manifestly they were intended to cover and do cover only the combination of the car and conductor, with an underrunning trolley capable of swinging freely on a vertical axis, and thus adapted to curves and irregularities in the conductor. And Judge Townsend held that Van Depoele was the first to make practicable the electrical propulsion of an electric railway by "a long rigid arm upwardly pressed and capable of universal movement." The defendant contends that the weighted spring, which is the only means for imparting upward pressure disclosed in the patent, must be read into these claims, for the reason that without it the claims would cover "inoperative and useless" combinations. It seems unnecessary to discuss the authorities cited by complainant in opposition to this contention (Deering vs. Winona Harvester Co., 155 U. S. 286, Taylor vs. Sawyer, 75 F. R. 301, Halloway vs. Dow, 54 F. R. 511). Although an additional device may have to be added to make the combination operative automatically, it is none the less operative without such addition. A boy seated on the roof of the car could impart the upward pressure, not as economically, nor as well as the weighted spring would, but quite sufficiently to insure the operation of the combination expressed in the claim.

It must be concluded then that claims 2 and 4 do not cover a spring or weight or torsion device, and it is conceded that they contain no switching device. In the earlier patent no claim is to be found, which does not contain either the spring or weight, or the switching device. It would seem then that these claims certainly are not obnoxious to the criticism of the Court of Appeals and that no "double patenting" is shown. And since the meritoriousness of the invention, and Van Depoele's priority was found by Judge Townsend in the Winchester avenue case, complainant should be entitled to hold what it has established after long and expensive litigation unless the case presented here is changed by evidence not before the court in that case. I cannot see that the Hunter and Deligny patents, which are the only new ones, are any more of an anticipation than were those introduced in the Winchester avenue case.

It is further contended that complainant has unreasonably neglected and delayed to enter a disclaimer of claims 6, 7, 8, 12 and 16 of the patent in suit, which were held void by the Court of Appeals. That decision, however, was rendered upon an appeal from an order, and complainant is naturally averse to finally relinquishing these claims, until it may have had an opportunity to apply to the Supreme Court for a certiorari, an application which it is useless for it to make, when only a preliminary order is involved. There seems to be good ground for delaying disclaimer.

The argument that by its disclaimer of claim 9, complainant has disclaimed the entire invention of the patent, which is therefore wholly void, is unfortified by authority and unpersuasive.

Infringement cannot be seriously disputed. Defendant's device is practically a duplication of that used by Van Depoele in New Orleans in 1885. Complainant may take order for injunction pendente lite, but when issued its operation may be stayed for thirty days to give defendant an opportunity to review this decision at this term of the Court of Appeals.

Feb. 7, 1898.

The Walker Company state that this decision will be appealed and vigorously contested.

THE STOCK MARKET

Trade and Commerce Growing.

While the recent severe winter weather has checked the distribution of goods a little, it has bettered some lines very materially, such as coal, heavy wear, etc. The demand for iron and steel is very active. Railway earnings are again good, business failures are small, bank clearings are larger and the money market is very easy. Stocks and bonds have been brisk and firm at higher figures in spite of reactions.

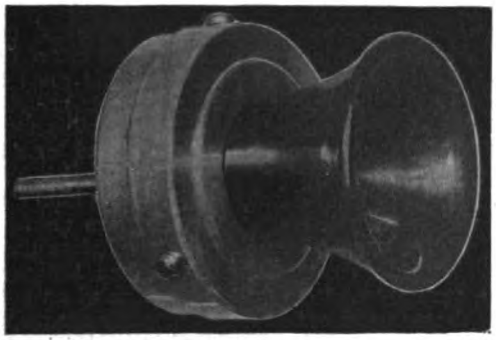
During the week 23,399 shares of Western Union were sold up to 92⅝. There was a marked advance in General Electric, 33,143 shares exchanging hands at prices that rose from 36½ to 39½, there being reports of large business and of financing plans to fund back dividends still unpaid. In Boston, Bell Telephone was strong, but dull, owing to the great storm which interfered with business generally. New York Edison's annual report is regarded as a great bull document. The stock is up to 133½ and there are rumors also of a stock dividend.

Copper is quoted at 11 cents, rising; steel rails are unchanged at $18.

TRADE NOTES & NOVELTIES

Logansport Coal Grain Microphones.

THE coal grain microphone transmitter manufactured by the Logansport Telephone Manufacturing Company, Logansport, Ind., can be placed on any telephone and will add to its appearance and efficiency. Only the very best of material is used in its construction. It is fully guaranteed not to pack. It is said to be an impossibility for it to get any moisture from the breath or atmosphere. Any transmitter that will absorb

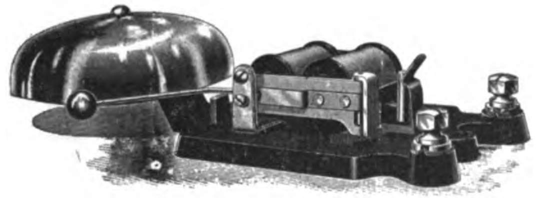


LOGANSPORT COAL GRAIN MICROPHONE TRANSMITTER.

moisture will pack. It gives a clear, distinct enunciation, and does away with harsh metallic rasping, scraping and squealing noises. It has volume for long lines; will work over any length line, either grounded or metallic, and gives the very best of satisfaction. It costs but a dollar, and is made by the Logansport Telephone Manufacturing Company, Logansport, Ind.

The Marlo Iron Box Bell.

The Proctor-Raymond Manufacturing Company, 444 Niagara street, Buffalo, N. Y., are receiving large orders for their new iron box bell called the "Marlo." This bell embodies many admirable features among which the following may be mentioned: A contact post which cannot loosen or change its position on the base, an armature which is brought very close to the core without touching it, thus utilizing the full power of the magnets, (the Marlo armature never sticks) a double adjustment of the con-



THE MARLO IRON BOX BELL.

tact and adjusting spring, made of one piece of phosphor-bronze, a gong which cannot turn or loosen, a hammer rod which will always retain its shape, and a cast-iron cover neatly japanned inside and out. The best material is used, the workmanship is first-class and each bell is in perfect adjustment for one or two cells.

Electric Elevator Wanted.

The Treasury Department, Washington, D. C., through the office of the Supervising Architect, is advertising until 2 o'clock p. m., February 16, 1898, for bids for all the labor and materials required for an electric elevator for the United States Courthouse and Postoffice Building at Little Rock, Ark. All communications and proposals should be addressed to the Supervising Architect at Washington, D. C.

STERLING ELECTRIC COMPANY, of Chicago, has been formed, with a capital stock of $30,000, to make apparatus. The incorporators are E. A. Biggs, John E. Hunt and W. I. Hall.

Oberg & Blumberg.

IN our issue of December 23, 1897, we referred to the Alexander-Chamberlain Electric Co., one of the most successful concerns in the field of electrical engineering and contracting in New York, and we now take pleasure in announcing the formation of a new concern, the offspring of this company, consisting of Messrs. J. L. Oberg and M. S. Blumberg.

Messrs. Oberg & Blumberg have opened offices at 853 Broadway, corner 14th street, with full facilities for executing contracts for electrical work of every description. Both members of this new and promising firm are well known to the electrical profession and have had a varied and extensive experience in the electrical business.

Mr. J. L. Oberg has been in the electrical field for the past thirteen years. Five years at the Thomson-Houston factory at Lynn; two years for the Thomson-Houston Company in New York, in charge of construction; two years for the Tucker Electrical Construction Company, in charge of construction; four years with the Alexander-Chamberlain Electric Company, as superintendent and in charge of construction.

Mr. M. S. Blumberg has been in the field for the past seven years, one year in the factory of the Zucker-Levett Chemical Company, manufacturing dynamos and motors, and for six years with the Alexander-Chamberlain Electric Company, in every capacity.

The firm starts out in business with the best wishes of a host of friends and if they are true to their motto that "The only way to procure success, is to make it," they are sure to procure a good share of it for themselves.

German Branch of the Garvin Machine Co.

The Garvin Machine Company, New York, have opened a branch house in Berlin, Germany, at 17 Burgstrasse, where they intend carrying a full line of their own tools and American machinery. This is an excellent move, and the Garvin Machine Company will practically be the first firm carrying a full line of their goods in stock in Germany. Judging from the demand for American machinery abroad, there is very little doubt that the Garvin Machine Company will do a successful business there. Several large shipments have already been made for stocking the branch and these will continue from time to time as the demands require.

Edwards & Co.'s Bells for High Potential Circuits.

Edwards & Co., 144th street and 4th avenue, New York, are manufacturing all styles of bells to operate on 110 and 500-volt circuits. Their construction is very simple and they have proved very successful wherever used. The cost is very little more than the ordinary bell. We are informed that Messrs. Edwards & Co. are at present the only manufacturers of bells which operate direct on high potential circuits.

Nearly 3000 Testimonials To Magnolia.

The Magnolia Metal Company during the last three or four months has received through the mails nearly 3,000 testimonials on Magnolia Metal, or to be exact, they received 2,827 distinct testimonials. These testimonials were received from every part of the United States and Canada, and were sent in by railway companies, steamship companies, rolling mills, iron and steel manufacturers of every kind and description, machinists, paper mills, cotton mills, woolen mills, wood-working establishments of all kinds, and practically every class of mechanical industry that can be mentioned.

These testimonials came to them in response to a circular letter sent out to all the mills and manufacturers of the United States and Canada, accompanied by a 15-inch rule sent with their compliments, and simply asking if they were users of Magnolia Metal, and, if so, what was their experience.

A very small percentage of concerns so addressed ever make response, and taking the number of replies actually received, giving testimony as to the superiority of Magnolia Metal, it has been estimated that at least 100,000 concerns in the United States and Canada are to-day using Magnolia Metal.

The above statement is a very remarkable one and shows the wonderful success that the Magnolia Metal Company has had during the past 10 or 12 years in introducing their metal among the mills, electrical plants, manufacturers, jobbers and dealers

of the United States and Canada; and their trade is equally as large in foreign countries. This shows what can be accomplished by having a good article well exploited and thoroughly advertised.

A Laboratory Lakon Transformer.

The Lakon Company, of Elkhart, Ind., received recently the following letter from Mr. W. H. Merrill, the electrician of the Chicago bureau of the National Board of Fire Underwriters:

"I have your favor of September 11, making inquiry concerning the 5-kilowatt transformer giving differences of potential as high as 40,000 volts which we purchased from you last spring.

"We have used this appliance continuously in our experimental work since its installation and the results obtained have been in every way satisfactory. It is to-day an indispensable feature of our laboratory equipment."

The Adams-Bagnall Electric Co.'s 1898 Souvenirs.

Manager C. W. Phipps, of the Eastern office of the Adams-Bagnall Electric Company, Cleveland, O., is sending out beautiful penwipers, consisting of red, white and blue cloth, surmounted by a large white button, to his many friends in the trade, who thoroughly appreciate this useful souvenir.

The Somerset, Ky., Lighting Contract.

The city of Somerset, Ky., has awarded the contract of furnishing lights to the city and its citizens to Mr. Beecher Smith, proprietor of the Somerset Ice Company. He will begin the construction of a plant about April 1, having a capacity of 1,000 16 candle power incandescent lamps, 100 40 candle power incandescent lamps for street circuits and 25 1,200 candle power arc lights for street circuits. There is a stipulation in the contract between Mr. Smith and the city that a duplicate plant is to be provided.

Removal of the Crouse-Hinds Electric Co.

On or about Feb. 15, Mr. F. W. Hawkins, Eastern agent for the Crouse-Hinds Electric Company and Pass & Seymour, will occupy the store 23 Dey street, Havemeyer Building, where he will continue the sale of the standard apparatus of the above companies.

H. C. Roberts Electric Supply Co.

The H. C. Roberts Electric Supply Company have opened a store at 831 Arch street, Philadelphia, Pa., occupying the first floor and basement, each 25 x 137 feet, extending back to the rear street, and have it well filled with a full line of electrical supplies of every description from the leading manufacturers of the country. Among the companies whose product they control in this section are the Bryant Electric Company, the Clifton Manufacturing Company, the D. & W. Fuse Company, the Gibbs Electric Manufacturing Company and A. O. Schoonmaker. Mr. Roberts is a thoroughly competent man, having had over thirteen years practical experience in the manufacturing and selling of electrical apparatus, starting in with the Schuyler Electric Company when in Hartford, afterwards accepting a position as foreman of the winding department for the Mather Electric Company, the Eddy Electric Motor Company and the Connecticut Motor Company. He also spent some time as traveling salesman for the latter. While in Hartford, Mr. Roberts purchased the Hartford Electric Time Company, which he afterwards sold to a stock company.

During the past seven years Mr. Roberts has been identified with the electrical supply business in Philadelphia and has a large circle of friends.

At the formation of the Electrical Trades Association Mr. Roberts was elected a member of the executive committee, which position he held until severing his connection with his former firm. Mr. Roberts starts in at an excellent time, under most encouraging auspices and with an already established trade.

PATTERSON, GOTTFRIED & HUNTER, 146 Centre street, New York, are agents for McClelland's oil purifier.

Queen & Co.'s New Cell Tester.

THE accompanying cut illustrates a new instrument placed on the market by Queen & Company, of Philadelphia, to meet the demand for a low-priced, accurate cell tester.

The Queen cell tester is sensitive and accurate, and the pointer dead-beat. The extreme uniformity of the scale permits of reading with accuracy from 0 to the maximum value for which the instrument is calibrated. The pointer always swings toward the positive pole and may therefore be used as a polarity indicator.

As the instrument is but 3½ inches in diameter and 1⅝ inches in depth, it may easily be carried in the coat pocket. The simplicity and careful construction of the meter render it proof against injury during transportation.

The accompanying flexible leads obviate the necessity and annoiance of hunting up stray pieces of wire for connectors.

A convenient range is from 0 to 10 volts, this permitting of testing several primary or storage cells either singly or in series.

The Queen cell tester is particularly recommended to those having the care of X-ray apparatus, or others having charge of instruments employing storage cells.

ADVERTISERS' HINTS

THE WESTERN ELECTRIC COMPANY, Chicago and New York, advertise "swinging tree" insulators for the protection of lines from swaying branches without cutting the insulation.

MACHADO & ROLLER, 203 Broadway, New York, wish it understood that they are in the lamp business to stay; that they are carrying a larger stock than ever, and that they are looking for competitive tests.

THE ELECTRIC STORAGE BATTERY COMPANY have removed their San Francisco office to 10 Front street, where their facilities are greater for handling their business in that city.

W. R. BRIXEY, 203 Broadway, New York, is now represented also by the Buffalo Engine Works, Buffalo, New York.

I. P. FRINK, 551 Pearl street, New York, states that his patent reflectors and reflecting chandeliers have lighted over twenty thousand churches alone.

THE McCAY-HOWARD ENG. COMPANY, 106 East German street, Baltimore, Md., say that by means of the Ries sockets, incandescent lamps may be operated as easily as gas.

THE WALKER COMPANY, Cleveland, O., illustrate their 50 kilowatt direct-connected steel generator and refer to the Waldorf-Astora as a model isolated plant of the Walker type.

F. E. BAILEY & COMPANY, 913 Betz Building, Philadelphia, Pa., are now the agents for the Armington & Sims Company, Providence, R. I.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, advertise Noxall annunciators.

TYREE & WILKINS, Lynchburg, Va., may be addressed for information regarding an opportunity to invest in a well equipped lighting, power and railway plant, which is to be sold under foreclosure on Feb. 28.

THE EVENING POST, of New York, advertises Mr. G. H. Guy's brilliant article on the Decade of Electric Railway Work, dating from the Sprague road at Richmond, Va.

NEW YORK NOTES.

THE WARD LEONARD ELECTRIC COMPANY report a surprising increase in the demand for their circuit breakers since January 1. The 100 ampere size seems to be the size most frequently required. The Ward Leonard Company has been obliged to increase its force in the line of circuit breakers several times in the last few months, and if the demand continues to in-

crease, will have to erect a third building, as their present two buildings are fully occupied.

THE BURGE-LEWIS ELECTRIC PROTECTIVE COMPANY, of New York City, has been formed. Capital, $50,000, and directors: H. I. Burge, of 110 East 109th street; M. H. Lewis, Simon Schwartz and Joseph Schwartz, of New York City.

ARC LAMPS manufactured and shipped from the factories of the General Electric Company within the past fiscal year, have exceeded 24,000. Many thousands of the enclosed arcs are now in service and the introduction of the alternating enclosed lamp has still further increased the sales.

THE AMERICAN COFFEE COMPANY, of Brooklyn, N. Y., are erecting a new power house in connection with their plant, which is about 70 feet wide and 120 feet long. The power house and boiler house have brick side wall construction and steel supports and roofing. Adjoining the boiler house is a coal bunker about 20 feet wide, which carries the supply of coal in a steel bin about 30 feet above the ground. The whole plant has been designed with convenience and economy in view, and can be very economically operated. The contract for furnishing and erecting the steel framework of the building has been let to the Berlin Iron Bridge Company.

THE E. G. BERNARD COMPANY, of Troy, has sent out to its friends a very neat and handsome thermometer mounted on a large decorative card. It is highly appreciated.

W. F. HARING, 609 Havemeyer Building, is the New York agent for Armington & Sims' engines, Providence, R. I.

OSTERBERG & SUTTON, consulting engineers, 11 Broadway, apparently have felt the drift of the better times. Among the plants in their office at present are the Harmonie Club in West Forty-second street and the Cushman Building, corner of Broadway and Maiden Lane, which are nearing completion, and amongst the new work which has come to their office since the beginning of this year are: The handkerchief factory of James F. White & Co. and two other factories for which they are now preparing plans; the lighting, heating and ventilating part for Smith College, a new theatre in the course of construction on the Boulevard; the Puritan Church in Brooklyn; the residences of Mr. Marks Arnheim in Long Branch, several private dwellings in Ridgewood, N. J., and the elegant private residences of Mr. Isaac D. Fletcher, corner of Seventy-ninth street and Fifth avenue and of Mrs. Jessie Converse, 5 East Seventy-eighth street.

NEW ENGLAND NOTES

G. M. ANGIER & CO., of 64 Federal street, Boston, have taken the entire selling agency of the Paragon arc lamps, previously sold by the Paragon Arc Lamp Company, of Boston. These lamps have already achieved for themselves a good reputation, and will hereafter be made open or enclosed and for all circuits. Messrs. G. M. Angier & Co. have long been favorably known to the New England trade, having represented the Eddy Electric Manufacturing Company for years in Boston, where they have done a most successful business. Mr. George Angier, the head of the concern, is particularly well known and enjoys a well deserved popularity, not only in New England, but throughout the whole country, as he has all his life been identified with electrical interests. In his hands therefore the Paragon arc lamp is bound to become a success, and with the many new styles of lamp which he intends bringing out in the near future, we expect to hear of Mr. Angier doing a large and successful business.

MR. H. C. THOMSON, of the Electric Gas Lighting Company, 195 Devonshire street, Boston, was elected manager at the annual meeting of the company.

THE NATIONAL ELECTRIC COMPANY, of Bridgeport, Conn., have contracted to make 700 clocks to control the lighting and extinction of gas jets at certain predetermined hours.

THE ANCHOR ELECTRIC COMPANY, by its treasurer, Mr. Norman Marshall, has brought suit for $25,000 damages against its retiring president, H. C. Hawks, for breach of contract and interference with its business and employés. An injunction was granted by Judge Holmes, of the Supreme Judicial Court, on Feb. 2, restraining Mr. Hawks from further interference with the business and employés of the Anchor Electric Company.

THE BERNSTEIN ELECTRIC COMPANY, which on the 20th inst. made an assignment, is in the hands of Gen. B. F. Peach, Jr., of Boston. It is his intention to continue the business and fill orders as promptly as possible.

THE BRYANT ELECTRIC COMPANY, Bridgeport, Conn., have received license from the General Electric Company to manufacture their Edison base specialties. This bids fair to grow into a large department of the Bryant Electric Company.

Vol. XXV. FEBRUARY 17, 1898. No. 511.

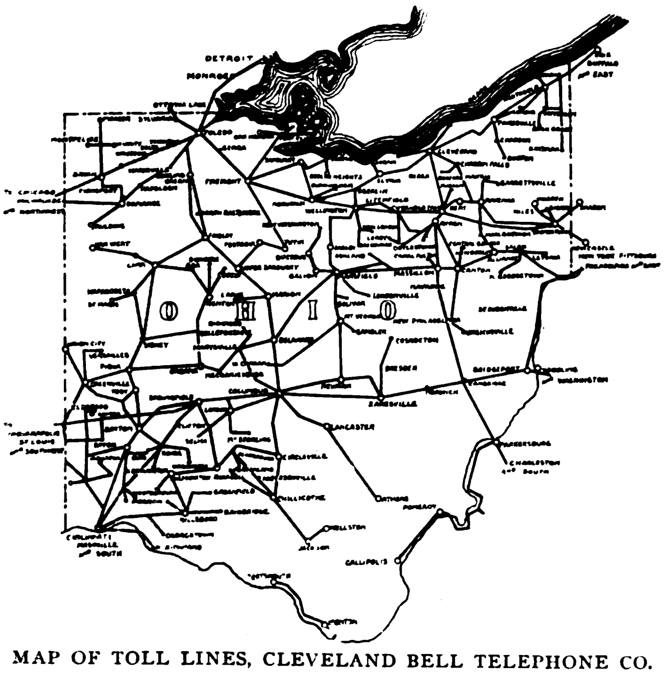
TELEPHONY AND TELEGRAPHY

The New Exchange of the Cleveland Telephone Co.

The Cleveland Telephone Co.'s Building.

SOME three years ago the Cleveland Telephone Company began work on a new building to accommodate its offices and its main exchange, and about the same time contracts were let for the re-equipment of all its exchanges. The building was completed in eighteen months, but the exchange equipment was not ready for installation until the fall of 1897. The time between September and January last was occupied in connecting up the new switchboard for the main exchange, and at 2 a. m. of January 9, the transfer from the old exchange to the new was made. The month which has elapsed since then has given every opportunity to test the working of the exchange and system, so that now something may be said regarding the equipment and the present and probable future results.

The Cleveland Telephone Company opened its first exchange in 1879, using what was known as the Scott system of switching. Later the Jones system was used, and this was followed soon after by the Western Electric standard switchboard. In 1889, the Western Electric Company installed a single-cord multiple switchboard for the company in its main exchange at an expense of $25,000. This board was built to accommodate 5,400 subscribers and was equipped at that time for 1,800 subscribers. Its equipment was subsequently increased to 2,800 subscribers, the board, with additions, representing an investment of about $50,000. Although only a little over eight years old, this switchboard became inadequate to the demands of the business, and it has now given way to the new equipment of the main exchange, the switchboard and apparatus in the latter costing something over $100,000. This re-equipment is along the line of policy of the Cleveland Telephone Company to keep abreast of the times, by availing itself of all modern improvements. Within the past few years the company has put in an extensive underground system, which now includes a total of 94,533 feet of conduit, containing 653,419 feet of duct. Within the city there are 7,370 miles of the company's wire underground, while the overhead plant consists of as much more. The overhead lines have been rebuilt throughout the city, and nearly, if not all the wires, are now copper. The company has five exchanges in the city—Main, East, West, Doan and Glen, with a total of over 5,000 subscribers. The re-equipment of the branch exchanges is progressing rapidly, and within a few weeks the entire system will be operated on a uniform plan. The work of re-equipment is in the hands of the Western Electric Company.



MAP OF TOLL LINES, CLEVELAND BELL TELEPHONE CO.

The main exchange switchboard, just completed, is set in a large, well-lighted and finely finished room, which is heated and ventilated by a blower system, the air being thoroughly sprayed and then dried and heated before being forced into the room.

The switchboard itself is the latest work of the builders and has given entire satisfaction. It is divided into 25 sections, two operators to each section, and is designed to accommodate a total of 5,400 subscribers. At present its capacity is 3,600 subscribers. It is equipped throughout with a system of signalling by means of incandescent lights. The wires are brought into the building underground, and are arranged on distributing frames in the "terminal room" in the basement. After going through the arresters, both carbon and heat coil, they are carried up in cables through a large shaft to the sixth floor of the building, where they are arranged on the intermediate distributing board. This board, which is a system of iron racks similar to a regular distributing frame, makes provision to carry the wires to and from the relay racks and then to the answering and also to the calling jacks in the switchboard. Under the multiple system each line is carried around the entire exchange, and at periodical intervals is taken to a spring jack, every line going to a total of 25 calling jacks—one jack for each section of the board. By this arrangement any operator in the exchange can tap in on the line without having to call for it through a second operator. The spring jacks are arranged in compact strips of 20, so compact, in fact, that within the reach of every operator are 3,600 lines. Each jack contains three springs, and altogether there are within the exchange nearly 100,000 jacks. The accompanying illustration of a section of the board gives a fair idea of the details of construction. The lamps for the subscribers terminating in this section are indicated by the rows of white dots toward the bottom of the picture and just above the keyboard. The keyboard is aranged to meet the demands of party line service. The center of the picture shows the 3,600 spring jacks which represent the subscribers within the reach of the operator. It will be seen that while an operator only answers calls for the subscribers represented by the lamps in

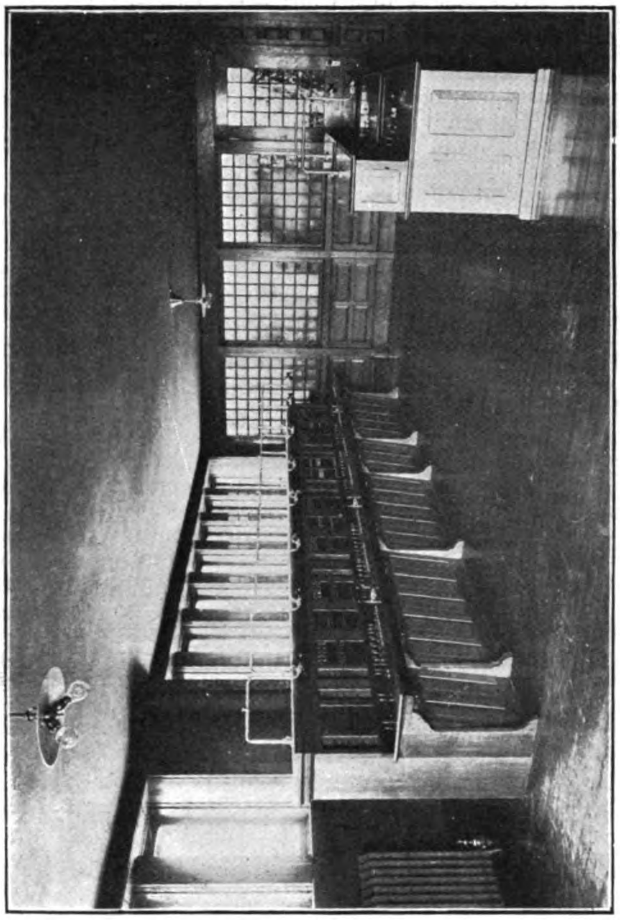
SECTION OF LOCAL SWITCHBOARD, CLEVELAND TELEPHONE CO.

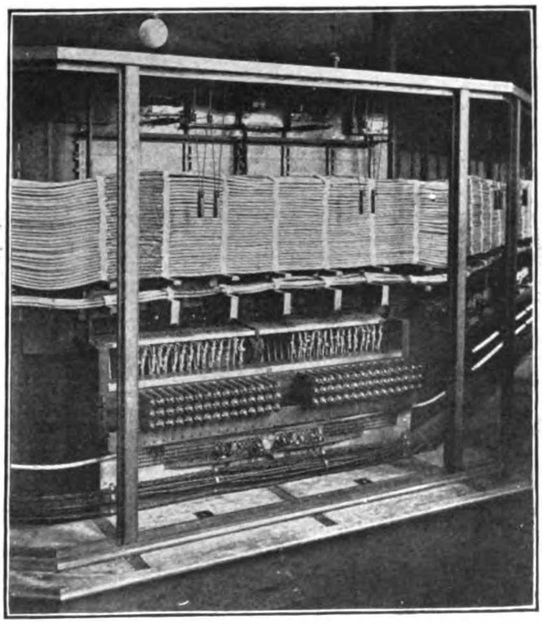


THE LONG DISTANCE ROOM, CLEVELAND TELEPHONE CO.

front of her, she has within her reach every line in the exchange, and facilities for reaching all branch exchange subscribers on trunk lines. When a subscriber takes his telephone off the hook, the lamp corresponding to his line flares up and the operator answers him with one of the small plugs shown in the picture. These plugs are on the ends of cords used for making connections. Connected with these cords are incandescent lamps which are used for disconnecting signals. When subscribers are through talking and hang up their telephones the disconnecting signal lamps light up, thus giving the operator automatic notice to disconnect.

A rear view of the switchboard, as shown in one of the accompanying cuts, gives one an idea of the complexity of wiring in the exchange. Each subscriber's line consists of three wires, two for the circuit, and one for an automatic test for the operator, to show when the line is in use. There are, therefore, exclusive of all trunk lines, 10,800 wires carried around the length of the board for the multiple system. The wires are placed in small cables which are tapped at regular intervals. The bunch of cables shown in the picture run around the switchboard and contain nearly 2,000,000 feet of wire. An idea of the detail of the exchange may be gained from the fact that in connecting the wires from these cables to the switchboard jacks over 300,000 soldered connections have been made. Adjoining the main exchange room is the "long distance" room, where all out-of-town connections are made and through which medium Cleveland subscribers can communicate with two-thirds of the people in the United States. In this room are "positions" for ten operators, with opportunity to double the size of the board.

Few people realize that a complete telephone plant involves a perfect power plant and equipment. In the power room are the two generators used for charging storage batteries, each two horse power; a three and one-half horse-power generator for lighting the signal lamps, two one-quarter horse-power generators for ringing, and forty-two cells of storage battery. The power



SECTION OF SWITCHBOARD, REAR VIEW, CLEVELAND TELEPHONE CO.

switchboard has, in addition to the regular switching apparatus, six ammeters, three of them recording, and two voltmeters.

The accompanying diagram shows the number of calls and the volume of business handled in the main exchange during the day. On certain days of the month each operator keeps tally, by means of pegs which she moves along the switchboard, of the number of calls she handles. At the end of every hour the totals are taken, and at the end of the day diagrams are made showing the number of calls handled in the exchange. The figures also show the total number of calls handled by each operator in the exchange, as well as the number of calls that each operator handles at any given time of the day. These figures are a basis for the transfer of wires to equalize the operating. A glance at the diagram shows that between 11 a. m. and noon there is a decrease of 2,000 calls per hour, so that apparently most Clevelanders go to lunch rather early.

The officers of the company are highly pleased with the working of the new switchboard. The expenditure of nearly $200,000 in the re-equipment of the company's exchanges is, of course, with a view toward improving the service and placing it in the

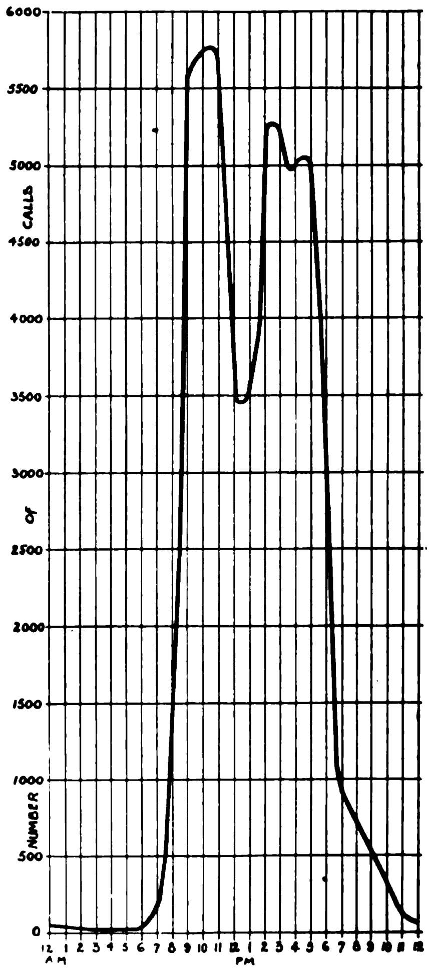


DIAGRAM OF DAY'S BUSINESS, CLEVELAND TELEPHONE CO.

front rank in the exchange service of the country. The change in the main exchange has already given gratifying results, and when the branches are uniformly equipped all subscribers will feel the benefit of the change.

The Cleveland Telephone Company is officered as follows: President, Levi Sprague; Vice-President, Chas. J. Glidden; Treasurer, Chas. A. Grant; Secretary, Geo. B. Perham; Directors, Levi Sprague, Chas. J. Glidden, Chas. E. Adams, W. J. McKinnie, Col. Wm. Edwards, E. P. Williams, Geo. W. Short, John E. Hudson, Gen. Thomas Sherwin, A. B. Hough and J. P. McKinstry. Mr. J. P. McKinstry is general manager; P. Yensen, superintendent, and C. T. McKinstry, manager.

Telephone Rights in Richmond, Va.

In the United States Circuit Court of Appeals Judge Simonton on Feb. 1 handed down an opinion in the case of the city of Richmond against the Southern Bell Telephone and Telegraph Company. The case involved the act of Congress of 1866 declaring that the streets of a city are post-roads of the United States. Judge Simonton holds that, while the act specifies only telegraph companies as entitled to its provisions, a telephone is to all intents the same thing and therefore entitled to its privileges. The Bell Telephone Company's charter having expired, the city exercised its stipulated right to revoke it, but was enjoined from interfering with the company's poles and wires. The effect of the decision is to modify the injunction so as to prevent the city from driving the the company from its streets, but the city is to retain its police power over it.

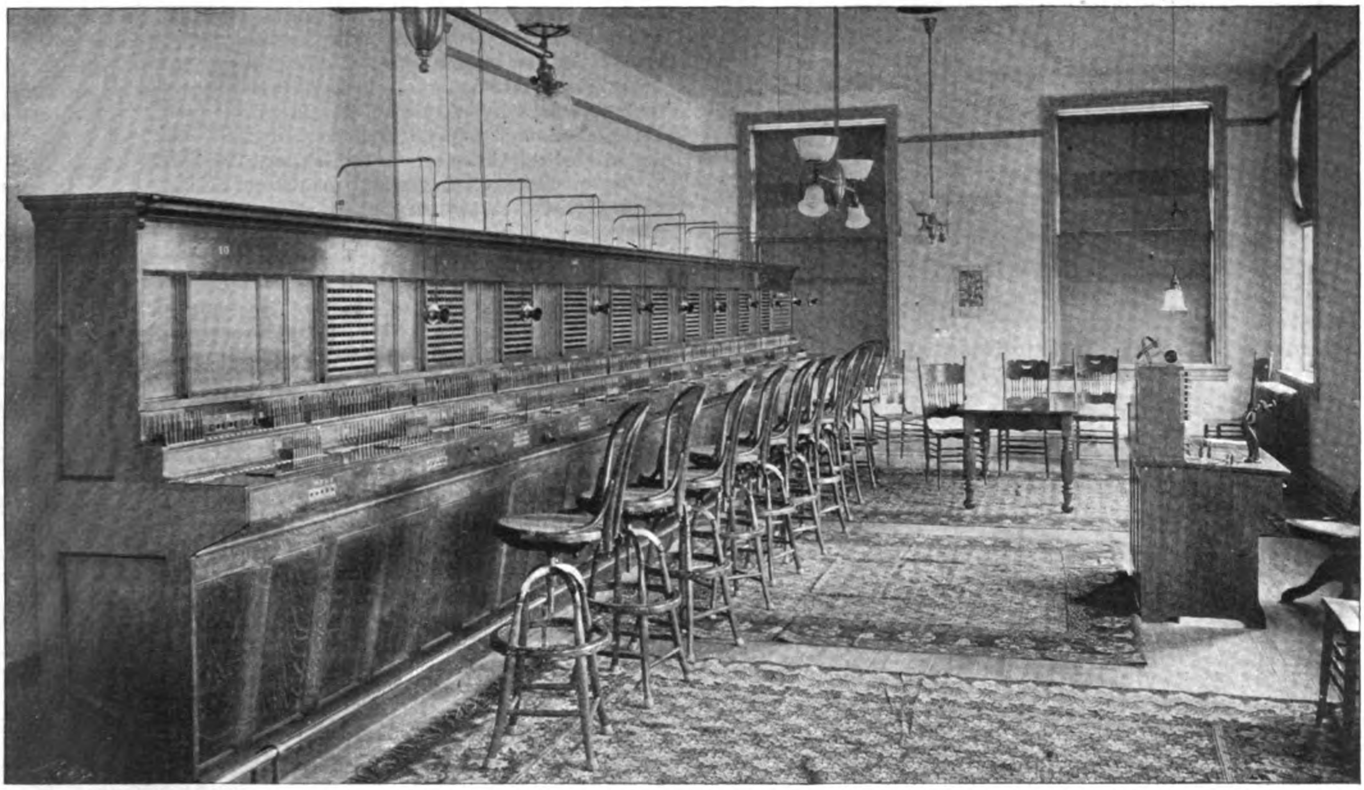
The Delmarvia Telephone Co.'s Exchange, Wilmington, Delaware.

ONE of the largest and most successful of the Eastern independent telephone exchanges is that of the Delmarvia Telephone Company, of Wilmington, Del. The company's exchange is at the corner of Seventh and Orange streets, in the heart of the business portion of the city of Wilmington. The Exchange Building, shown in the figure, is a substantial and handsome structure, specially designed for the telephone business. The second and third stories of the building are occupied by the company for the business of the exchange. The offices of the company are in the second story front apartments on this floor, and in the rear of the offices is the cross-connecting room. In this room is the cross-connecting board, which is a departure from the plans of all other boards in use. Owing to its peculiar construction it greatly facilitates the connection of the subscribers' telephones from outside lines with the switchboard proper.

The switchboard is already wired for 1,500 subscribers. A Crocker-Wheeler motor-dynamo is used for ringing, charging the storage batteries and for light and talking purposes. Power generators are also provided for the possible failure of the electric current received from the outside. These generators are attached to a water motor and can be turned on at a moment's notice. This makes the system practically independent of the outside supply of electric current. The switchboard is amply protected against lightning or excess of current by lightning arresters and fuses.

The switchboard is unlike others, and the entire system is extremely rapid and easy of manipulation. When a subscriber rings at his telephone, the drop or shutter on the switchboard representing his telephone falls before the operator, and at the same time a white light appears which attracts attention, and can only be extinguished by replacing the drop. This is done by placing the answering plug in the "spring jack," representing the telephone through which the call has been made. This restores the drop or shutter to its normal place and puts the operator into communication with the caller. When the calling plug is put into the "spring jack," representing the caller's telephone, she moves the lever which rings the bell, and as soon as he answers, puts the parties into communication with each other. When the communication has terminated between the subscribers, a short ring by one or the other of them causes another "clearing out drop" to fall; then, for fear the subscriber may want to call for another number, the operator presses upon a listening key and asks, "Through?" and, getting no response, takes down the connection by removing the plug from the "spring jack." When the parties are through talking, and the operator who received the call has removed the plug from the "spring jack" of the telephone of the caller, a colored light, denoting the section which first called, will appear before the operator, notifying her that the transfer should be removed from

THE DELMARVIA TELEPHONE EXCHANGE, WILMINGTON, DEL.



THE DELMARVIA TELEPHONE EXCHANGE, WILMINGTON, DEL.
(Switchboard Built by Western Telephone Construction Co.)

the spring jack. This transferring requires only a few seconds time to connect any two telephones. An operator can reach and control, without changing position, the connections of over 300 subscribers' instruments.

In connection with the switchboard there is a chief operator's desk, which is connected with every operator's section and every subscriber's telephone. When a drop falls, showing a white light at the operator's section, a colored light appears on the chief operator's desk, indicating the section at which a call has been made. Should this colored light remain an unusual length of time, the chief operator, by pressing a button, opens communication with the operator at whose section the apparent delay occurs, and immediately ascertains the cause for the failure to make the called-for connection. The chief operator is thus aware of the working of the whole switchboard.

Every morning at 7 o'clock the lightning arresters on the cross-connecting board are carefully examined, to see whether any of the fuses have blown out during the night, thereby cutting out any of the subscribers' lines from the switchboard. Also every morning at 9:30 the operators call up the subscribers in order to ascertain whether the lines are working properly. The replies to these inquiries are sent to the chief wireman in the cross-connecting room, and lines are tested by a peculiarly constructed plug, both toward and from the subscriber's telephone to locate any injury to the lines.

The working of this system has been successfully inaugurated by the Delmarvia Telephone Company, and although in operation but a short time, it has already made the new line very popular.

The company has erected 400 telephone poles, upon which about 450 miles of No. 12 B. & S. hard drawn copper wire, and about 50 miles of cable have been strung, and 175 miles of underground conductors, connecting all overhead lines at the various terminal poles with the central office, have been laid. The conduits containing the underground cables are of vitrified clay, which will not rust or rot, nor can they be attacked by electrolysis. These conduits are protected from mechanical injury by being laid in a base of cement from three to five inches thick, and under a covering of the same material, making protection which is impervious to pick or shovel. The underground cables are of the National Cable Company's manufacture, each one containing 100 twisted pairs of No. 19 B. & S. copper wire, paper insulation and spirally wound. The switchboard and instruments were manufactured by the Western Telephone Construction Company, of Chicago.

The officers of the company are Thomas McCorkle, president; Charles N. Trump, vice-president; Henry Baird, secretary and treasurer; Capt. Frank Wood, superintendent. The directors are: Henry Baird, John Barron, Henry C. Conrad, Thomas McCorkle, George I. Speer, Calvin I. Swayne, Charles N. Trump and Charles E. Phelps, Jr.

On the Electrical Conductivity of Metallic Conductors.[1]

BY EDOUARD BRANLY.

THE remarkable experiments in wireless telegraphy made by Marconi have called attention to the conductivity of discontinuous metallic substances, and to the experimental study of it first made by me in 1890 and 1891. Marconi used my tubes and filings without modifying their method of working, and even if the special mixture of the metallic powders to which he gives the preference seems advantageous, it is easy to recognize that such a complicated mixture is not necessary, and it appears to me that the sensibility must chiefly be attributed to the state of conductivity of the powder employed. Having already[1] stated the conditions which increase the sensibility, I have now just taken up the matter again, and have confirmed my former results by new experiments. I have recognized that the most sensitive substances are those which offer a very slight conductance as compared with that of the galvanometer, and in several cases to attain this I have exercised, by means of a weight, a pressure of from 50 to 100 grms. on a layer of filings from 1 to 2 mm. thick, enclosed in an ebonite cup between two metallic electrodes. I obtained in this manner, with a circuit made up of the powder, a Daniel cell and a sensitive mirror galvanometer, a deflection of a few millimetres on the divided scale. With mixtures of insulating and metallic powders, when the proportion of the former was great, this limiting state was only reached with enormous pressures.

As a matter of fact, I did not trouble about measuring the pressure exerted. I enclosed the metallic filings in a narrow ebonite chamber placed vertically, the filings being as usual between two metallic rods to serve as electrodes, one of which could be moved forward or backward at will by means of a screw. I turned this screw until a very slight conductance was established. The apparatus, which was well constructed by M. Gendron, worked most satisfactorily. It allows of rapid manipulation, enables the powder employed to be varied, and dispenses, for the purpose of experiments, with a delicate tube analogous to those used by Marconi. Sometimes it is difficult to limit to a few millimetres the scale deflection obtained on tightening the screw; but if the conductance obtained corresponds to an elongation of 50 to 100 divisions, it can be reduced by a slight shock. The needle of the galvanometer returns to zero, and then, although the conductance is 0, the substance is in reality in the same condition as if it offered a slight conductance. For the moment I am not trying to synchronize the oscillator and receiver, nor to parallelize the electric radiation, as would be necessary for transmission to a great distance. I am confining myself to subjecting successively my apparatus and a tube of Marconi's alloy[3] to the same action, ususlly that of a spark from a small Wimshurst machine (plate 35 cm. diameter) placed at a distance of 25 metres. As formerly, my filings are sifted, and the better they conduct the finer they are taken. Many metals and alloys of definite composition give very good results. Aluminum and aluminum bronze behave well, but they are not the only ones, and it would be necessary, in order that the enumeration might be useful, to give not only the name of the metal but also the coarseness of the filings suitable and even the age of the filings.

In 1891[4] I emphasized the properties of metallic powders surrounded by insulators and agglomerated by fusion. These properties were the same as those of metallic powders plunged in air or a rarefied gas. The variations in conductivity of these solid substances occur under the same circumstances, and they also disappear on receiving a shock or on being heated. My experiments do not appear to have been repeated. I had moreover to grope my way to a certain extent in the beginning. If Lodge had in his turn experimented with solid substances he would probably have renounced his term "coherer."[5]

The mixtures of filings and insulators can be varied in a variety of ways: resins and filings, shellac and filings, balsam and filings, etc. I often give these mixtures the form of pastilles of about 1 mm. thickness and 2 or 3 mm. in diameter. Instead of pastilles it is very convenient to use thin sheets of collodion and filings, gelatine and filings, celluloid and filings, etc. The preparation of these sheets is very simple and rapid, and allows the proportion and coarseness of the metallic grains to be varied at will. Whether pastilles or pellicles be used, they are treated in the same way as the powders. They are placed between the electrodes of the screw apparatus mentioned above, and the screw is turned until a very slight conductance is obtained. If necessary, this conductance is destroyed by a shock. The sensibility may be extremely large, equal or greater than that of the most sensitive powders.

I do not insist on the sensitization by the first effect; this is a point of great importance mentioned several times in previous publications. Let us also note that the intensity of the shock to produce the return must be regulated. It is needless to remark that the value of the continuous current traversing the sensitive substance plays an interesting part; special effects are obtained on reducing the electromotive force to one-twentieth, one-fiftieth and one-hundredth of that of a Daniel cell or on using thermo-electric currents. I will add that mixtures can be obtained which only remain conductors for a moment and return immediately, without requiring a shock, to their original resistance. It ap-

[1]From the Comptes Rendus of December 6, 1897.

[2]See two articles on the variations of conductivity under electrical influence in La Lumiere Electrique of May and June, 1891, Vol. XL., 448. A resumé of the principal phenomena was published in the Bulletin des Séances de la Société Francaise de Physique, 1891, pp. 135-141.

[3]I am using a tube made in London according to Marconi's instructions. It is much more sensitive than some others produced in the same way, and it was placed at my disposal by M. Ducretet.

[4]Comptes Rendus, January 12, 1891.

[5]My tubes of filings received the name "coherers" from Lodge, and this name has been generally accepted. The expression is based on an incomplete examination of the phenomenon and on an inaccurate interpretation. I proposed the name "radioconductors," which recalls the essential property of discontinuous conductors of being excited by electric radiation. M. Ducretet uses my various radioconductors in the apparatus he has constructed to realize "Hertzian Telegraphy" without wires.

pears even that effect can be produced with any substances by varying the method of operating in a suitable manner.

The Great South Bay Postal Submarine Cable Successfully Laid by the Okonite Company.

Marine Observatory Tower at Fire Island.

On January 25 the six-mile submarine cable of the Postal Telegraph-Cable Company was successfully laid by the Okonite Company in Great South Bay, on the Ocean side of Long Island, between Fire Island and Conklin's Point. This cable is the heaviest of that kind ever manufactured, and due to the dangerous character of the Great South Bay the job of laying the cable was one of the most difficult pieces of submarine cable work performed in recent years in this part of the globe. On account of the many problems involved and the responsibilities of such an undertaking, the Postal Telegraph-Cable Company requested the manufacturers of the cable to lay it themselves. This the Okonite Company agreed to do, and the successful completion of the work reflects great credit on the general management and careful engineering of the undertaking.

The Postal Telegraph-Cable Company have recently established several marine observatories just outside the port of New York for the purpose of reporting the arrival of steamships at the earliest possible moment. The most exposed and distantly located of these observation towers, shown in Fig. 1, has just been completed at Fire Island. A substantially constructed air line runs from this observatory, which is located on the Ocean side of Fire Island, to the Bay side of the Island, where it connects with the six-mile cable just laid. This cable crosses the Bay and lands at Conkling's Point. Here it connects on a terminal pole, shown in Fig. 2, with another land line which runs due north to the Long Island railroad tracks. This land line is a splendid example of modern telegraph construction and carries two copper wires weighing 210 pounds to the mile. From the point where the land line meets the Long Island railroad tracks, it follows an old overhead line for some miles along the railroad, then along the highways until the outskirts of Brooklyn are reached, where it goes underground to No. 4 Court street, Brooklyn, one of the Postal Company's offices. From here the line runs via an aerial cable, carried on the elevated railway structure, to the Brooklyn Bridge, thence over the Brooklyn Bridge by another aerial cable to the New York terminus, from where it goes underground to the Postal Company's main office at 253 Broadway, New York City. Before reaching this office, however, this important line has passed through several towns on Long Island and three of the boroughs of Greater New York.

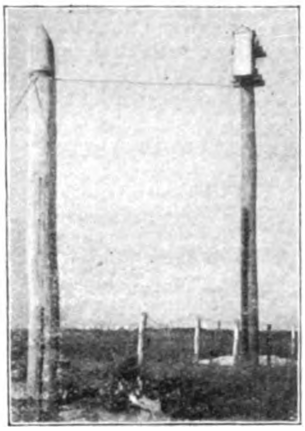


FIG. 2.—TERMINAL POLE AT CONKLING'S POINT.

FIG. 6.—LAYING THE SHORE END.

To get a clear idea of the amount of preliminary work and planning required for the successful carrying out of this undertaking, it will probably be as well to follow the cable on its journey from the Okonite Company's manufacturing plant at Passaic, N. J., to its final resting place in the waters of the Great South Bay. The cable, which is six miles long, was made in one length, and weighs about sixty-five tons. It is one inch and three-quarters in diameter, contains six Okonite wires arranged as three pairs, and is heavily armored with galvanized iron wire. The cable weighs four pounds to the foot, which is about five and a half times the weight of an ordinary ocean cable. An elevation and cross section of the cable are shown in

FIG. 4—WINDING THE CABLE ON REEL AT FACTORY.

FIG. 8—GUIDING BLOCK FOR PAYING OUT CABLE.

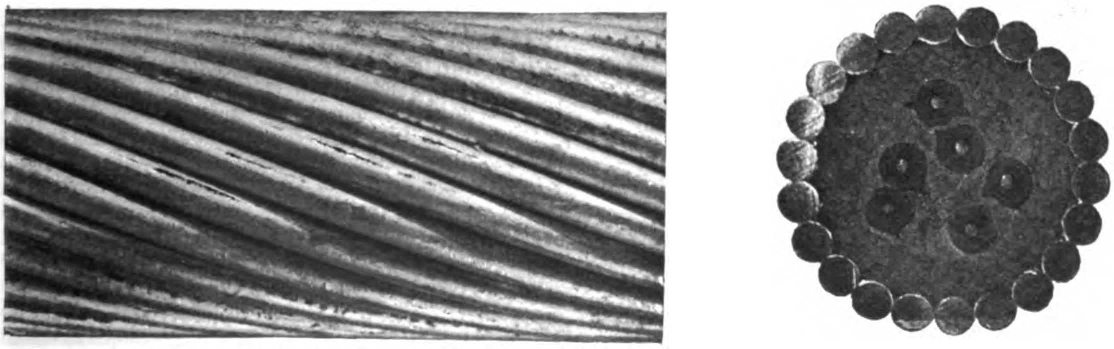

FIG. 3.—SIDE VIEW AND CROSS SECTION OF OKONITE POSTAL CABLE.

Fig. 3. The cable as manufactured was coiled in the large testing tank at the Okonite Company's factory and put through the usual severe tests. After satisfactorily passing through these, the end of the cable was led through a window to a heavy reel erected on bearings on a flat car alongside the factory buildings. A leather belt was passed around one end of the reel and carried through the window to a shaft in the factory, as shown in Fig. 4. By this means the reel was turned and the cable was wound upon it. It required three of these reels and three flat cars to transport the cable.

From Passaic the reel laden cars were transported by as direct railroad connection as possible to New London, Conn., where they were run out on a pier and the cable was unwound and coiled on the deck of a large wrecking scow, shown in Fig. 5.

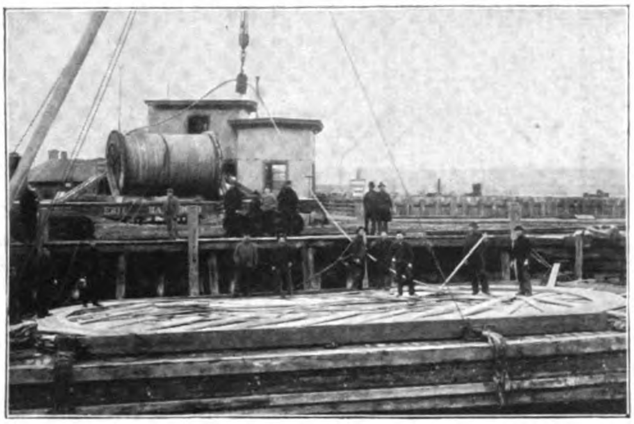

FIG. 5.—COILING CABLE ON SCOW AT NEW LONDON.

Such a roundabout road had to be chosen because New London was the nearest point at which a scow of the requisite size and of sufficiently light draft could be obtained. This was made necessary owing to the shoals and sandbars in the Great South Bay over which a heavy draft scow could not pass. Capt. T. A. Scott, the famous New London wrecker, was in charge of this part of the work and the skill he displayed in handling the heavy mass of material was truly wonderful to an observer unaccustomed to this class of work. The scow was eighty-five feet long, thirty-five feet broad, and drew about three feet of water with the sixty-five tons of cable on its deck. The cable was passed from the reels on the cars through a heavy snatch block suspended from a derrick on the scow and was coiled on the deck without a kink in six layers, containing about a mile each. This is the first time, it is believed, that a cable of such length and size has been laid in such a manner. Heretofore, heavy reels have been used with various degrees of satisfaction. The manner in which the cable was paid off from the deck of the scow in laying left no doubt in the minds of the experts who were present as to the success of this method.

FIG. 7.—PAYING OUT CABLE FROM SCOW.

When the cable was coiled down and made fast, the scow was taken in tow by a heavy, sea-going tug and towed down the Sound to Fire Island. The scow was anchored near the terminal pole of the Fire Island land line and a heavy rope was carried ashore in a small boat, passed through a pulley made fast to the terminal pole, and carried back to the scow. The rope was attached to one end of the cable, the other end of the rope being passed around a steam winch. In a very few minutes after the winch had started, the end of the cable was ashore, where it was made fast, as shown in Fig. 6. A light draft tug drawing but four feet of water was then made fast to the scow and the tedious, risky and "tricksome" journey across the Great South Bay was commenced with all its possibilities of mishap.

The tug was piloted by an expert bayman, Capt. George Saxton. Owing to his thorough knowledge of the channels and bars the cable was successfully laid in the wonderfully short time of four hours without a single hitch or delay from any cause. The cable was paid out over the stern of the scow in much the same manner as it was carried aboard, see Fig. 7. A guiding block, shown in Fig. 8, was rigged up on the stern of the scow through which the cable passed and an extemporized brake was used to regulate the speed of paying out.

Valuable assistance was rendered in the shipping and laying of the cable by Mr. R. D. Blish, the cable expert of the Southern New England Telephone Company, and the laying of the cable was witnessed by Mr. E. B. Baker, general superintendent of the Southern New England Telephone Company, who was greatly pleased with the methods and means used. Mr. E. G. Cochrane, general superintendent of construction for the Eastern division of the Postal Telegraph-Cable Company, was present, as well as Capt. W. L. Candee and Mr. George T. Manson, of the Okonite Company.

MUNICIPAL AFFAIRS

Public Control, Ownership or Operation of Municipal Franchises?—VII.

With Special References to Electric Lighting.*

By R. R. BOWKER.

(Vice-President and General Manager New York Edison Co.)

THE true objection to trusts is not economic, but financial and political. The enormous advances in water and gas stocks show that in these cases the social increment value has in fact gone, not to the public, but into private pockets. It is not always the original investor nor indeed the present investor who profits by such advance, for with increasing profits and a diminishing rate of interest the price of the stock goes up until it pays only a normal return, but more probably the speculative "operator." But this objection can be fairly met by the limitation of franchises and the fair regulation of prices, limiting the return say to ten per cent. on actual investment, with proper depreciation and amortization allowances, or providing that profits above a normal return shall be shared with the municipality. The latter is the better way, because it leaves to private management an incentive to efficiency and economy, and like economic rent it does not tend to increase price. Such regulation should be not by legislative interference, but by provision in the grant or charter. Private corporations doing public service should also be required to print full reports. These provisions would tend to assure fair prices, prevent over-capitalization, and leave little margin for corruption.

It is rightly urged in favor of municipalization that a city can borrow for investment purposes on its bonds at a very low rate of interest. But it is evident that a private company, safeguarded by reasonable conditions, can borrow on its bonds on almost as close rates, certainly within one per cent., and the higher rates have been chiefly because of the uncertainties incident to our American methods. The increase in market value of stocks as dividends have increased, show that in a well-settled business, as that of the London water companies and the New York gas companies, the shareholders in a private com-

*This paper is written from the point of view of the economist and citizen, but with the data and experience gained as the executive of the New York Edison Company. To my mind, this should not involve opposition of interests; as he most serves his party who best serves his country, so he most serves the interest of a public-service company who best serves the public. I mention the relationship, however, to forewarn readers of any unintentional bias. It is difficult for any outside the business cited, in an academic discussion, to obtain real bases of comparison.—Reprinted by permission from Municipal Affairs, the Reform Club Quarterly.

pany no longer obtain much above the normal rate of interest, which is steadily decreasing.

POLITICAL OBJECTIONS TO MUNICIPALIZATION.

The final and strongest argument against municipalization is, even more than against trusts, political rather than economical. The charge against private corporations that many of them have been among the worst breeders of political corruption is, in some but not in all cases, probably true. This is in great part the fault of public opinion. The public does not pay adequate salaries to its legislators. Men taken from their personal business during the earning months of the year do not receive enough for their living and their campaign expenses. Those of honest purpose find it not easy to resist the "opportunities" offered them by clever lobbyists, while the less scrupulous, sent both from city and country districts, almost openly take or ask money bribes. Public opinion lends an easy sanction to the fallacious argument, that it is better to surrender to highwaymen a part of the property in one's charge than to lose it all, which permits men of the highest personal integrity and honesty to condone or overlook, through an indirect chain of agents and lobbyists which evades responsibility, what they would not personally or in their own private interests permit. It is indeed highly to the credit of our legislators that so many, under such temptation, are ready, as I have found, to protect a corporation against "strikes" when it is honestly trying to serve the public and is prepared to make its facts and figures fully known. But to take passage on a pirate ship so as to avoid danger from pirates, is not altogether wise, and to give over an industry to the spoilsmen by municipalization so as to prevent corruption, is scarcely the common sense or commendable course.

The opportunities for and invitations to political corruption in our great cities and in our state legislatures, if great industries now in private hands are taken over by the city or the state, would be the most serious menace possible to really democratic and American institutions. In the past few years the growth of paternalism in our government, and of the restrictive policy in our trade relations, foreign and domestic, has turned American thought unconsciously toward what is practically state socialism, the direction or misdirection of the affairs of an individual or an individual enterprise by governmental machinery. The American theory of government is based on individual freedom, the right of an individual to manage his own affairs without interference, unless he interferes with his neighbor. Democracy and socialism are in this sense absolute contraries. Only a generation ago this country freed itself from one form of industrial slavery; it is the great argument against the municipalization of industries that it would be not only a step, but a long stride, toward the new industrial slavery of state socialism.

Tonawanda, N.Y., Votes Down a Municipal Plant

The Tonawanda Board of Trustees decided recently to submit a proposition to the taxpayers of the village at a special election to be held on January 29, providing for the issue of bonds to the amount of $25,000 for establishing a municipal lighting plant that will generate power for 225 lights. The vote was duly taken and resulted as follows: For purchase of city plant, 65; against, 324. A very reasonable proposition made by the local company and already noted in these columns will probably be accepted.

Some Municipal Examples.

Debate is on in Des Moines concerning municipal ownership of a gas plant, and the court house is the forum for Sunday afternoon addresses on the subject before the members of the Union Labor League and others. J. S. Polk, the talker on a recent Sunday, warned his hearers to avoid the first step into uncertainties, if not failure. The logical sequence of municipal control of light supply was municipal control of water, of street railways, and of all the other "public utilities." That such control elsewhere was rarely successful, Mr. Polk proceeded to show. In Alexandria, Va., he said, the city sold gas at $1.62 and lost $6,239.03; Philadelphia sold at $1.50 and lost $106,144; Richmond sold gas at $1.50 and lost $42,405.97 annually. As to street railways, none are owned by municipalities in this country, and only four in Germany, the centre of advanced socialistic thought, and those in small cities. In Switzerland there are three. In no other European country are any owned by municipalities, except in Great Britain, where there are six, as against 125 owned by private concerns. Of these six cities, Blackpool has operated at a profit of $992 a year. Huddersfield has lost $311,000 in fourteen years. Leeds has netted a profit of about two per cent. Plymouth lost $5,430 last year. Sheffield has not paid interest. Glasgow paid interest on £515,556 and netted about $50,000. It must be considered also, in this connection, Mr. Polk said, that both labor and capital are cheaper in England than they are here, and that higher rates of fare are charged. Under the tramway act of Great Britain these roads are allowed to charge two cents a mile for transporting a passenger, there are no transfers, no tickets are sold at a discount, and the longest ride in any one of the cities (Glasgow) is five miles, for which the city charges six cents.

LETTERS TO THE EDITOR

R. M. Hunter on Railway Motor Support Patents.

THE recent decision of Judge Wheeler in the case of the Sprague Electric Railway & Motor Co. vs. the Union Railway Co., et al., involving the motor support under the Sprague patent, is far more important than the Walker Company endeavors to make out or admits in its published criticism of the decision. The Walker Co. should not play the ostrich act and think, because it prevents itself seeing by burying its head in the sand, others are to be reduced to the same condition. Now this Sprague patent is of fairly early date, and aside from the question of who actually invented the device, the features involved are patentably different from the prior art set up, not only specifically in the direction pointed out by Judge Wheeler, but generically also. The construction involving the hinging of the motor to the axle by bearings connected to the field magnets and having a revolving armature supported within the field magnets at a distance from the axle by suitable bearings movable with the field magnets, whereby the armature shaft (in which the power originates) is always maintained in the same axial relation with the axle and continuously connected to it through gearing or other power transmitting devices, and further, in which the free end of the motor, together with the power shaft (the armature shaft), is flexibly suspended either from the vehicle body or truck frame, is novel, useful and clearly distinguishable from the prior art. It is peculiar to the art of electric propulsion and differs radically from the Adams 1883 patent, and is "independent" of it as Judge Wheeler says. I may add that looking at the improvement from a legal standpoint, the construction to be given to the claims sued upon, takes the structure covered thereby beyond the pale of the prior art, and clearly distinguishes from all those alleged anticipating devices comprehending the hinging of the engine or motor upon the axle, which is also made to subserve the function of the power shaft. The Walker Company may play with words, but the cold, hard facts remain that the motor suspension in common use embodies invention generically, provided we do not divest it of its useful elements. The idea that the Court intended to confine the scope of the decree to such narrow limits as to require specific brackets directly bolted to the pole pieces as bearings for the armature shaft, is believed too flimsy to be worthy of serious thought. A patentee is entitled to common sense equivalents, and the modifications in design of the motor since the date of the Sprague patent should warrant some liberality. In any event the bearings are in all cases rigidly connected directly or indirectly with the pole pieces to the extent of keeping the armature in the proper relation therewith while otherwise movable relatively to the axle, and this is all that is required. If the Walker Company wishes to deceive itself it must not try to lead others astray also.

R. M. HUNTER.

Philadelphia, February 7, 1898.

DR. LOUIS DUNCAN, of Johns Hopkins University, has become consulting engineer of the Third Avenue Street Railroad Co., New York, for its plans for an extensive system of conduit trolley traction.

VOL. XXV. NEW YORK, FEBRUARY 17, 1898. No. 511.

A Splendid Electrical Exhibition.

IT is as we ventured to predict a month or two ago in regard to the Electrical Exhibition that will be held in Madison Square Garden next May. The matter has been taken up with the greatest energy and interest by the whole art and industry, so that already the management is able to issue its preliminary list of over 100 exhibitors, whose allotments of space represent between 20,000 and 30,000 square feet. This is a really wonderful showing, being not less than five times as great as at the corresponding period two years ago. Those who do not now hasten to preempt the little space unoccupied will certainly find themselves badly left in an exhibition destined to attract a great number of people and sure to have a good influence on all the electrical lines of trade.

The list printed in our pages this week presents an impressive collection of the leading names in the art and guarantees some very fine exhibits. There will evidently be a good demonstration of electric power uses. This is admirable, for it is a lesson which at this moment of reviving trade can be driven home, leading to the choice of electricity for power distribution in new and old manufacturing plants. Of methods of current generation there promise to be not a few, including not only the old dynamo, but its later competitors. The most interesting developments, indeed, may be expected in regard to the engines shown, for it is plain to see that gas or oil engines may score this time not less heavily than did the steam engines at the show in 1896; and the novelties in this line will attract widest public attention. In electric railway work again some most interesting exhibits will be displayed, including several ingenious methods of perfecting the underground trolley and the third rail system. In lighting, we think some beautiful, novel and startling effects, with direct application in the art, may be safely expected. The tremendous gains of business on the part of the local lighting companies throughout New York show how ripe the public is for practical persuasion to use more electricity than ever before.

And so we might go on, in review of this remarkably encouraging list of foresighted exhibitors who have already put themselves in line and looked out for good spaces. But aside from the commercial aspects of this exhibition, there are its educational features, and these in the excellent hands of the New York Electrical Society, supporting the Auxiliary Committee, are already being carefully developed. At an early day, the management will announce its plans in this department, but meantime it may be said that no electrical show ever held previously will have made any such effort in behalf of the art to inform the intelligent public, and to interest the younger members of the community in the great agency which will dominate their life far more than it has that of those of us who have grown up during the forerunning age of steam.

One other feature may be noted here. They who regard this exhibition as "merely local," if there be any such, make the greatest mistake in the world. No one says or thinks that of a show in London or Paris; no one has any reason for regarding as local an exhibition held by manufacturers from all over the country, amongst over 3,000,000 resident population, and in one of the greatest of our exporting cities, at a time when the foreign demand for our electrical, steam, hydraulic and machinery products is increasing by leaps and bounds. The markets north and south of this country are not yet as fully ours as they should be by any means; and while we are selling such apparatus in large quantities to England, France and Germany, those countries are still getting orders that should be ours, all the way from Florida to Patagonia, to say nothing of the Far East. To convince export merchants of their opportunities in the electrical line, will be one of the benefits of this exhibition, and not its smallest; while we happen to know of the intention of foreign purchasers to visit it and make the most of the occasion. Consumers visiting this country to give contracts for apparatus dislike greatly having to travel long distances to see some of it, and at this show they will find in profusion the objects they seek and want to buy.

Some Considerations on Diesel's Rational Heat Motor.

IF we should plot a curve representing the increase of efficiency of any one class of machinery such as the dynamo or steam engine, for example, letting the ordinates represent the years and the abscissæ the efficiency, we would find that the curve is remarkably regular, devoid of any sudden change of direction. In fact so regular has this curve been for the steam engine during the past quarter century that the increase of efficiency during a coming year could be predicted at the end of the one that preceded it. This fact has had the effect of causing engineers to regard with incredulity any reported sudden increase of efficiency of any class of machines, especially prime movers. For many years the dynamo and steam engine have been developed side by side and it may even be said that the development of the latter is due to a large extent to the rapid strides which have been made of late in raising the standard of efficiency of the former. The dynamo has now reached a state bordering closely on absolute perfection. The steam engine is one of the most perfect instruments of modern industry, brought to that height by the ablest engineers. Nevertheless, the best triple expansion steam engines of over 1,000 h. p. utilize only from 12 to 13 per cent. of the whole heat contained in the fuel, and small engines down to 50 h. p. only 5 per cent., provided condensation is used. The gas and petroleum motors, too, have received their due share of attention and their efficiency has now been brought up to from 20 to 30 per cent. This, according to Prof. Ewing can be raised, by following the proper lines, to 40 per cent., and regarding the great problem concerning steam generation, we may recall Redtenbacher's words, when he wrote to Zeuner, that "the principle of steam generation and utilization is wrong; it is to be hoped that at a time, not far off, the steam engine will disappear after we have acquired clear ideas on the nature and the effects of heat." These two statements, the

one by Ewing relative to the gas and petroleum engines, and that of Redtenbacher regarding the steam engine, justify the taking of a most optimistic view of the remarkable claims advanced for the Diesel rational heat motor which we describe and illustrate on another page.

The operation of this remarkable motor may be briefly described as follows: An auxiliary air pump compresses the air to about 500 pounds per square inch, storing it in a separate reservoir from which it is led into the cylinder along with the oil or gas or coal dust, and compressed still further, the temperature due to compression rising to the ignition temperature of the combustible. The fuel begins to burn and generates still higher temperature and pressure by doing so; at the end of the stroke the consumed gases, still at a high temperature, are led into a larger low pressure cylinder which brings the pressure down so low that the succeeding exhaust is comparatively quiet. With American petroleum this motor gave an efficiency of 34.2 per cent. as against similar motors of the ordinary type of 20 to 30 per cent. and the best steam engines of 12 to 13 per cent.

The fact that the Diesel motor works with nearly equal economy at light and full load is a strong point in its favor, while the absence of any igniting apparatus and its self-starting properties must commend themselves to all engineers.

The motor is to be shortly introduced into this country, and its advent is to be welcomed if it fulfils the claims of its inventor. We can discern distinctly its vast influence for good on the industry of electrical generation and distribution.

The Rights of Telephone "Deadheads."

A DECISION has just been rendered in Washington, by Associate Justice Cox of the Supreme Court of the District of Columbia, which ought to prove of some service in checking the impositions under which local telephone companies suffer. The proprietor of a hotel in Washington, as a subscriber to the telephone, allowed all the patrons of the hotel to use it free of charge. The amount of "deadhead" business was naturally very large under such conditions, and the company, failing to check it, tried to remove the instrument. A temporary injunction stopped them, but the judge in continuing the injunction has imposed certain requirements on the plaintiff, which, if respected, would remedy the evil. Before mentioning them, we will again express our own belief that a measured service is the only way out, the experience of the New York Telephone Company proving our assertion.

Judge Cox, for example, says that boarders in the hotel can send for a baggage wagon, but are not entitled to order theatre tickets or ask for stock reports. He points out that the guest in the hotel does not get free telegrams, or free cabs, or free messengers. Why, then, free telephones, simply because the instrument happens to be available? Why not free newspapers and free boot shines?

Judge Cox puts his finger on one point often forgotten in this land where liberty and license are not infrequently supposed to be the same thing: "When the subscriber allows others to use his telephone it is an abuse of the time of the telephone operator. It is also an infringement on the rights of the Bell Telephone Company, which receives a royalty from the defendant. Furthermore, it is an infringement of the rights of other subscribers. It is very annoying for a subscriber to call for a certain number and be told that the connection he wants is busy, that being due to the fact that a non-subscriber is using, free of charge, the telephone with which connection is desired." Some day it will be realized that all such encroachments are to be resisted, for the common welfare; and that the best way out is to pay for what you get, so that if anybody else wants to use your telephone he knows that, like a postage stamp, it is costing you three, five or ten cents, and that someone has to pay the bill.

Electric Enterprise in Small Western Towns.

THE rapid development of that portion of the United States which lies west of the Missouri River, and the utilization of the vast water powers of the mountainous regions, have again and again given evidence of the enterprising American spirit and the quick ability of our Western people to recognize that in the introduction of modern machinery lie the best possibilities of growth. It may therefore be of interest to note a few of these enterprising communities from a list compiled by "Cassier's Magazine," which gives ample proof of the above assertions. The town of Lander, in Wyoming, which had its progress impeded for want of the latest means of artificial illumination, ordered an electric light plant which had to be hauled over bridle paths for 150 miles from the nearest railway station before it reached its destination. Sheridan, also in Wyoming, had only 600 inhabitants and was 200 miles from the nearest railroad. The plant, packed in very small pieces, was hauled 200 miles. Buffalo, in the same State, having 600 inhabitants, thought 44 miles a comparatively short distance to haul its electric light plant.

In Idaho the town of Lewiston, with 2,000 inhabitants, had its electric light plant hauled on boats for 80 miles up the Snake River. Murray, with 700 population, had a 60-mile overland passage to accomplish. Turning to places on railways it is found that Newcastle, Cambria, Rawlins, Rock Spring, Green River, and Evanston, in Wyoming, and Pocatello and Idaho Falls, in Idaho, have each an electric light plant, though the population of not a single one of these towns exceeds 300. Boise City, Idaho, with 8,000 inhabitants, has not only an electric light plant, but a system of trolley cars. The three small mining camps of Cœur D'Alene, Wallace and Wardner use electricity for lighting purposes all the year around, while their available water power is used to run the mills for stamping ore. In winter when the main water supply is frozen, the electric current is connected with the stamping mills, and lighting and power are both furnished by a lavish expenditure on coal at $10 a ton. It is often said that one must go to Europe for examples of such small installations, but the far West is proof to the contrary; and the adverse conditions there met are, we imagine, far more severe than exist across the Atlantic, if only from the fact that these points are so remote from manufacturing centers.

Electric Versus Steam Elevators.

AT a recent fire in the city of New York another of the numerous advantages of the electric elevator was clearly brought to light and its presence might have avoided much loss of valuable property and the endangering of the occupants of the building. A number of tenants who were within some of the premises when the fire was discovered, endeavored to seek safety by signalling for the elevator. The latter, which used steam as a motive power, was not running at that time, and was useless as a means of escape as it would have taken a dangerously long time to get up sufficient steam to put it into operation. The firemen, who could have made valuable use of the elevator by carrying their hose on it to the upper floors, were compelled to climb up a number of steep stairs with it, helped by reporters, in order to reach the flames. However, had an electric elevator been installed in that building, the throwing over to the street mains, which run into every large office building to-day, would have taken only a few seconds. Life and property would be imperilled to a less degree if the public would realize the boundless advantages of the electric elevator, such as flexibility of operation, safety, and the rapidity with which it can be made ready for action. Besides, electric motors can be used instanter for pumps and hose.

MECHANICAL

The Diesel Rational Heat Motor.

An Important Advance in Prime Movers.

IT is well known that the steam engine after its inestimable work during the past centry and with the improvements it has undergone, during recent years, is still regarded as a lamentably wasteful and imperfect motor. In regard to its state of development, it is a well known fact that in the best triple expansion steam engines of over 1,000 h. p., from 12 to 13 per cent. only of the whole heat contained in the fuel is converted into actual work; only 9 per cent. from smaller double expansion engines down to 150 to 200 h. p.; 5 per cent. from small engines down to 50 h. p., provided condensation is used, and far less from the smaller steam engines and those without condensation.

The question naturally arises, what becomes of the remaining 87 to 96 per cent. of the coal consumed? In the first instance, 20 to 25 per cent. are partly lost in the furnace and partly in creating draft in the smokestack, incidentally also causing the smoke nuisance which is becoming more annoying from day to day, especially in large cities. The remaining 70 per cent. are lost through radiation at every point, through condensation and cylinder losses, friction, etc.

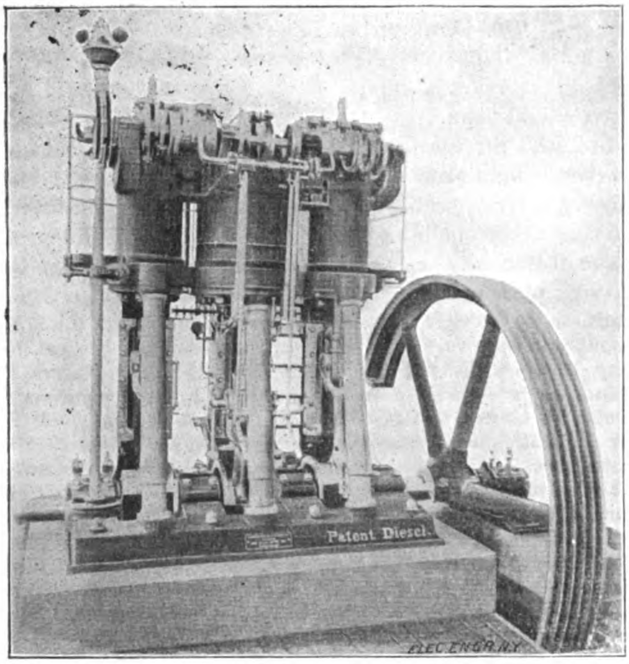

FIG. 1.—150 H. P. DIESEL RATIONAL HEAT MOTOR.—PERSPECTIVE VIEW.

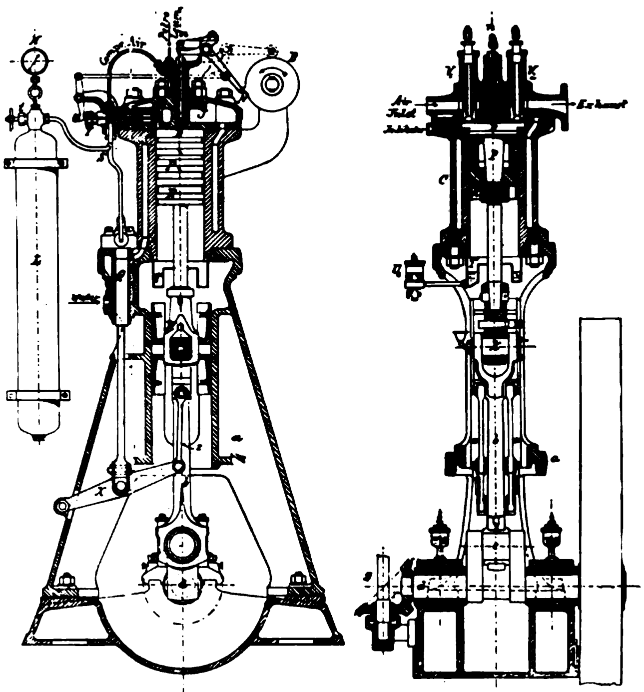
A recent invention by R. Diesel, Munich, who has been working on the problem of heat motors for the last fifteen years, claims to have created a complete revolution in the production of power. The Diesel motor, which is no longer an experiment, but an established commercial apparatus, pretends to nothing less than to finally supersede the steam engine. For many years Mr. Diesel worked over this difficult problem until at last the idea struck him to use the air, which was employed as a working medium, not only as such, but simultaneously as a chemical medium, thus rendering it feasible to do away with the steam boiler. Thus he arrived at an idea which had long ago been applied in gas and hot air engines, namely the combustion of the fuel in the cylinder itself.

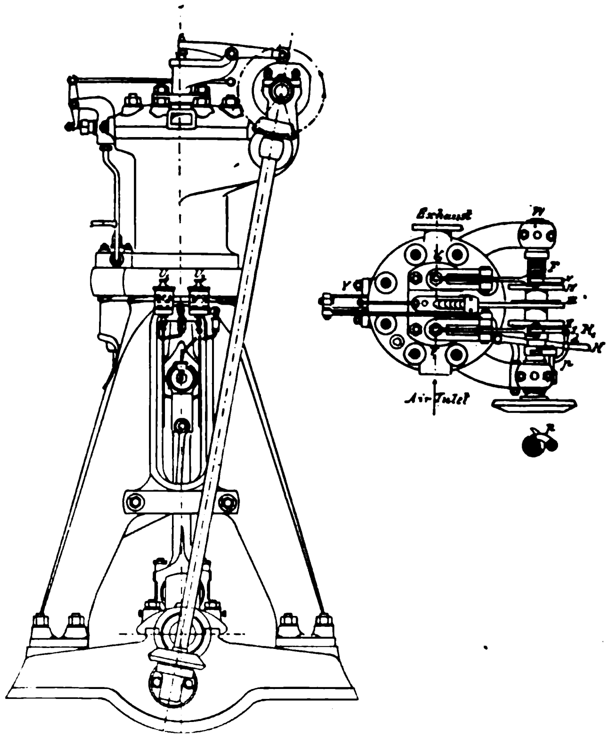
Before enumerating the four conditions pointed out by Mr. Diesel as the most important and fundamental ones for an economical caloric engine, it may be well to give his definitions of ignition and combustion. He states, in an address delivered before the Verein Deutscher Ingenieure:

In every process of combustion two kinds of temperatures are to be distinguished. 1. The temperature of ignition; 2. The temperature of combustion. The temperature of ignition is that temperature to which a fuel must be heated to ignite it in presence of air. The temperature of combustion is that temperature subsequently generated by the chemical process of combustion after ignition has taken place.



FIGS. 2 AND 3.—DIESEL RATIONAL HEAT MOTOR.—CROSS SECTIONS.

The conditions then named by Mr. Diesel are as follows: The combustion temperature must be generated not by the combustion and during the same, but before and independent of it after ignition had taken place, by mechanical compression of pure air. To deviate from the perfect process by directly compressing the air adiabatically instead of first isothermally from 2 to 4 atmospheres and then adiabatically to the 30 or 40 fold.



FIGS. 4 AND 5.—DIESEL RATIONAL HEAT MOTOR.—SIDE VIEW AND PLAN OF VALVES.

By so doing one realizes the first of the required conditions, i. e., the generation of the combustion temperature by mere compression with pressures which are two and four times lower than those used in performing the perfect cycle.

The fuel must be introduced gradually into the air which is compressed adiabatically to the combustion temperature in such a manner that the heat generated by gradual combustion is absorbed in the so-called nascent state, in consequence of a corresponding expansion, i. e., by mechanically cooling off the gases so that the period of combustion is going on constantly isothermally. It is evident that the fuel, in order to fulfil that condition, must be changed in its physical composition to a gaseous, liquid or powdery form. That is to say that through the combustion and during the same, no, or a relatively small increase of temperature is caused, an idea which seems to be absurd after having heretofore always effected the increase in temperature by the combustion and during the same.

The fourth condition also presents a revolution of ideas hitherto considered correct, according to which the combustion had to be carried on with as little surplus of air as possible, while he contends that a considerable surplus of air, whose amount can be determined theoretically in each special case, is necessary.

During the years 1893 to 1897 motors of various types and using different working media were constructed which would fulfil the above rational conditions. The petroleum motor completed in 1897 was extensively experimented with by experts and representatives of industrial establishments. All of these trials were carried on with the greatest accuracy, with repeated examination of all apparatus and instruments used, and with absolute conscientiousness. They lasted at times one, but mostly several days, and embraced all working conditions of the motor and its regulation under all complicated conditions.

In order to compare the efficiencies of the boiler engine transformation with those of the new motor, let us call n_1 the efficiency of the boiler; H the caloric value of the fuel, n_2 that portion of the whole heat n_1 H contained in the steam that can be converted into work; n_3 the so-called indicated efficiency, that is the portion of the theoretical cycle convertible into work; n_4 the fraction of the whole indicated work which the engine delivers at the flywheel, the remainder being absorbed by the friction of the engine, n_4 being therefore the mechanical efficiency.

In the comparison we will at once be struck by the following facts:

First: The efficiency of the steam boiler n_1 in the new engine equals 1, as the whole combustion heat of the fuel is transferred to the working body, air.

Second: The theoretical efficiency n_2 varies as has been proven in several instances, from 50 to 70 per cent.; the smaller value corresponds to the simple single cylinder engine represented in Figs. 2, 3, 4 and 5, and which, on account of its simplicity, has a very extended field of application; the larger value corresponds to more complicated arrangements, especially for compound system, which Mr. Diesel considers to be the only correct construction for those engines aiming at the utilization of heat. This value n_2 is twice as much as that of steam engines, and represents the superiority of the new motor over steam engines and explosion motors, whose value for n_2, according to Clark, varies from 33 to 43 per cent.

Third: The actual indicated work varies, according to experiments, from 34 to 40 per cent.; the indicated efficiency n_3 of this simple engine is thus 70 to 80 per cent., consequently, it is by far superior to that of the steam engine, and materially higher than that of the explosion motors.

Fourth: The mechanical efficiency n_4 of the new engine, varying between 71 and 75 per cent., is, therefore, materially less than that of the steam engine and explosion motors. It cannot, however, be denied, says Mr. Diesel, and there are good reasons for the supposition that the mechanical efficiency may gradually be increased to that of other engines. Be that as it may, for the present we only have to consider facts, and then give the economical result, which is:

$$n = n_1 . n_2 . n_3 . n_4 = 1 \times 0.50 \times 0.72 \times 0.74 = 0.266:$$

i. e., 26.66 per cent. of the total heat is converted into effective work.

As the fuel used for the experiments was usually refined petroleum, a comparison with motors of this kind only is permissible. The results of the tests have all been graphically represented and a careful study of them has justified the inventor in claiming the following advantages for the new engine:

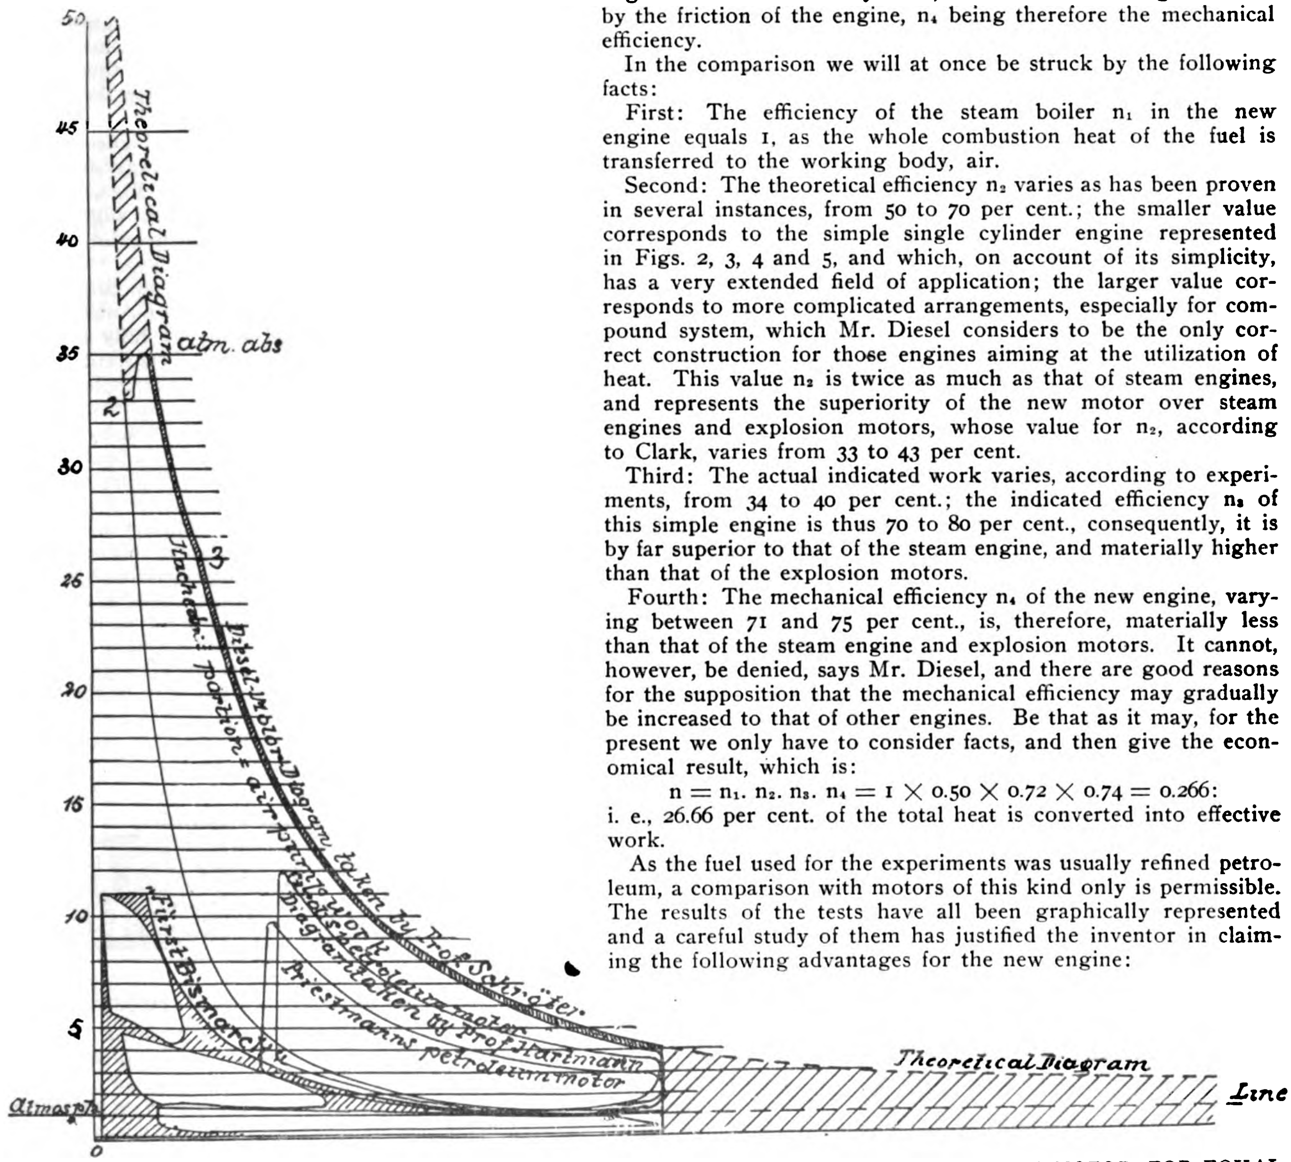


FIG. 6.—COMPARATIVE DIAGRAMS OF STEAM ENGINE, PETROLEUM MOTOR AND THE RATIONAL HEAT MOTOR, FOR EQUAL CYLINDER VOLUMES AND DRAWN TO THE SAME SCALE.

The first is, the very small increase in fuel consumption while the work is decreasing.

It can almost be expected that the consumption per horsepower, within the limits of the engines in practical use, is nearly constant, while with all other petroleum engines it increases enormously during diminution of load. This peculiarity is explained by the very strong increasing thermal efficiency accompanying decreasing work, whereby the loss of mechanical efficiency during less work is, to a greater extent, counterbalanced. No other engine has this peculiarity, not even the steam engine, and this is of vast importance; in practice, an engine never works with its highest load, and, therefore, in reality, never keeps up the results obtained during tests, nevertheless, the new engine is actually accomplishing this.

The second of the valuable qualities is its small dimensions, as compared with the explosion motors constructed up to the pres-

ent day. At full work the cylinder dimensions of the most successful of the motors are 50, 60 and even 100 per cent. larger than those of the new one, supposing, of course, all motors to have the same number of revolutions, as indicated by the diagram. This is proved, by Fig. 6, rendering conspicuous the diagram of the steam engine (ocean grey-hound "Fürst Bismarck"), of the petroleum explosion motor and the rational caloric motor. It is evident how the tendency prevails to draw out the diagram from the corner of the co-ordinate system into space. From the fact that the diagram of the new motor has, by far, a greater area than that of the explosion motors, its mean pressure is respectively greater, and the dimensions of the engine are smaller for the same work. The immediate consequence of this is, that the piston, connecting rod, flywheel-axle, etc., of the rational motor can be built not stronger, but weaker than those of the same capacity explosion motor. These facts remove the most important of the objections brought into the field against the new system, viz., that the dimensions would be so great as to be impracticable.

A third material advantage of the new motor is that the work can be regulated exactly as with steam engines, by changing the oil supply, i. e., the admission period. According to the work done the diagram becomes narrower or broader (for the actual scale see Fig. 6), and, indeed, the engine is controlled in an astonishingly exact manner by the governor, as the loading and unloading of the engine during the trials have proven. This has never been known to fail.

A fourth very valuable quality of the new motor is its continual readiness for service. As stated before, the motor in the condition that it was when last put out of action, and after an indefinitely long pause, is ready for starting without any heating or preparations of any kind whatever.

The fifth and, perhaps, best quality of the engine is the entire absence of interior soiling after continuous long service, due to the perfect combustion under conditions arising from the process. From this it also follows that the exhaust gases are entirely invisible and nearly odorless during the greater period of running, and only become visible when the engine is very much strained.

Less material advantages, but, nevertheless, advantages of great importance, of the new engine are: The absence of any ignition apparatus, whether electric, by flame or by incandescence; the absence of lamps, generating or pulverizing apparatus, of mixing apparatus, etc., and, in consequence, its simple construction.

These peculiarities, making the motor equivalent to the steam engine (but with the omission of boiler and appurtenances), are increased by its low fuel consumption, amounting to 215 grams (7.58 ounces avoir.) and less per brake horse-power hour, according to results obtained at normal working, and not when the greatest work is done.

Although the new motor may be regarded entirely developed as a petroleum motor, its field is still more extensive. It has already been mentioned that the running with illuminating gas was carried on just as successfully as with liquid fuel. Experiments to this effect have been made and the results can be produced at any time. The new engine will, however, first obtain its entire comprehensive importance when it is able to use common coal, and when it can be manufactured in units of 100 h. p. and more. In both directions experiments are being made by the machine shops at Augsburg; a large 150 h. p. motor has been built, Fig. 1, and a fuel gas generator is already built. The experiments themselves, and the development of the engines and apparatus for this kind of service, necessitate, of course, a great expenditure of time; nevertheless a comparatively quicker solution of these questions may be expected, in view of the vast amount of experimental material accumulated during a period of many years.

The experiments conducted with the motor by Professors Schröter and Gutermuth and others have shown an indicated efficiency in the utilization of 34 to 35 per cent. of the heat contained in the fuel under normal conditions, and 38 to 40 per cent. at half load; these figures are about 50 per cent. higher than the best indicated gas engine efficiency obtained up to the present (attaining, according to Dugald Clark, 27 per cent. in several cases, but generally remaining considerably below that figure), especially when taking into consideration normal conditions at varying and unusual loads.

The general plan of operation of the Diesel motor may be summed up in the following words:

Pure air is compressed in the cylinder of this motor, thus generating a temperature of about 600 degrees C. The fuel to be used, such as gas, petroleum or powdered coal is thereafter injected into the compressed air where it is gradually and completely burned up at a much lower temperature than ever before accomplished. During combustion and during the succeeding expansion, it is entirely turned into work. The injection and combustion of the fuel takes place as the piston in the cylinder begins its return stroke. It ceases when it has reached about one-eighth or one-sixth of its way back and it is so regulated that the increase in the temperature created by the compression of the air and subsequent combustion of the fuel, is reduced by cooling off due to the work done during the succeeding expansion. Thus, practically there is no increase in sensible heat since the heat caused by the combustion of the fuel is immediately turned into power and the motive power thus gained is only reduced by the small amount required for the compression of the air.

Our illustrations show one type of the Diesel motor in perspective in Fig. 1, cross sections of it in Figs. 2 and 3, and a side view of it and the plan of the valves in Figs. 4 and 5. Fig. 6 shows comparative diagrams of a steam engine, a petroleum motor and the Diesel motor, for equal cylinder volumes and drawn to the same scale.

Expert commissions from all civilized countries, including Japan and Australia, have been sent to Augsburg, where the motor has been in actual operation for fully a year, and their unanimous testimony indicates that its advent must be hailed as the beginning of a new chapter in the application of heat as motive power. The motor has been examined and warmly approved by eminent authorities, among them by Lord Kelvin, of Great Britain. It is expected that the suppression of boilers, coal bunkers and condensers, will revolutionize the machinery of torpedo boats and sea-going vessels.

At Nürnberg, Diesel's motors are being built at present for street cars and general railroad work. Mirrlees, Watson & Yaryan, the world-renowned marine engine builders, of Glasgow, are building reversible engines on the Diesel system, while European locomotive works are adapting the system for locomotives.

The Diesel motor has been patented in all countries where patents are granted for inventions and the rights for the United States and Canada have been acquired by a company since incorporated under the laws of New York State as the "Diesel Motor Company of America," with offices at No. 11 Broadway, New York. The motor will be one of the novelties at the May Electrical Exhibition.

X-Rays in Accident Insurance.

THE Röntgen rays promise to be of much help in determining the extent of injuries to policy-holders in accident insurance companies. One dishonest claimant injected irritants in his arm not long ago, and asked the company for a considerable sum for a broken wrist. A surgeon was employed by the company, and although the member was swollen considerably, presenting much the appearance of a fracture, the X-rays showed the bones to be in perfect condition. The patient was naturally chagrined at the discovery, but still thought he was entitled to $25, which was of course refused.

A still more interesting case was that of a New Orleans man who was thrown from his bicycle, fracturing his forearm. After considerable treatment a physician pronounced the bones united and the patient doing well. The latter, however, thought differently, experiencing sensations in his arm which caused him much pain and uneasiness. The Röntgen rays were resorted to, showing clearly that the bones had never united, and had not even been properly set. A splinter of considerable size was also found to be irritating the skin. The defect was soon remedied, and the period of disability for which the patient could make claim against the company consequently shortened. These cases are thought to have an important bearing upon such matters, since accident companies are constantly having suspicious cases to deal with, in which it has been heretofore almost impossible to determine accurately the justice of the claims made.

MISCELLANEOUS.

Waterproofing Fabric by the Electric Current.

Of the numerous commercial applications of electricity recorded recently, but few can compare favorably in importance with the use of the electric current for making fabrics waterproof or water-repellent. That this has been successfully accomplished has just come to our notice, and while we know of no severe tests to which the treated fabrics have been subjected, a description of the process and the experiments which led up to the discovery will certainly prove of interest and value.

Several years ago, Mr. Henry L. Brevoort, of Brooklyn, a well-known electrical and mechanical engineer and expert, made the following observation while employing pieces of wet cloth between conducting plates: After the cloth had become dry, and he wanted to wet it again, the cloth repelled the water as if the latter were mercury and had therefore become waterproof or water-repellent. The phenomenon led him to investigate whether a reliable process for waterproofing fabrics by electricity could not be devised. Mr. Brevoort commissioned Dr. L. K. Boehm to undertake these experiments, which resulted in perfecting a process of making fabrics water-repellent by means of the electrical current which, together with a theory to explain the action taking place, is described as follows: The process consists of the treatment of fabrics, threads, cords, or ropes of cotton, wool, silk, or other animal and vegetable substances, in the shape of fabrics or otherwise, by an electric current passing from a metallic conductor placed against one side of the goods when wet, through the goods, and to a conductor of metal or carbon placed against the other side of the same, whereby they are rendered water-repellent, and other useful properties are conferred upon the fabrics.

We will refer first to the sides of the goods being treated as positive and negative. By the positive side of the goods is meant that side which is to be against the plate or roller connected with the carbon of the battery (the negative element), or the like pole of a dynamo. By the negative side of the goods is meant that side of the goods which is against the conductor connected to the zinc (the positive element) of a battery, or the equivalent pole of a dynamo. The goods which it is desired to treat—say, cotton sheeting, for example—are wet with water, which is preferably neither alkaline nor acid. The wetted fabric is then placed between two conductors. The one on the negative side may be of metal or carbon or any material which is a conductor of electricity. The one on the positive side must be of metal capable of being oxidized, preferably aluminum, tin or zinc. The conductors, if they are in the shape of plates, should be accurately made, so that their opposing surfaces will press upon the goods at all points. Their shape is immaterial so long as this condition is present. If the conductors are rollers, they should be accurately turned, so as to bear upon the goods at all points along their length. A current of electricity is now passed from the positive side through the goods to the negative side. This current of electricity will, if of the proper strength and if applied for the proper time and when the conductors are pressing on the goods, confer upon the goods certain desirable properties or characteristics, among which may be particularly mentioned that it will produce a peculiar waterproofing or water-repllent effect thereon, which will be observed when the goods, after being dried, are again immersed in water. After the electrical treatment the goods are to be removed from between the conductors, which are not to be at any time during the operation in contact or short-circuited, and the said goods are then to be dried in the air or preferably a heated room or in an oven.

It is found that the goods are waterproofed, or their fibres are made water-repellent, at those points where the conductors were pressed upon them and where the current passed. This waterproofing is produced, it is believed, by the formation on the positive conductor of a metallic oxide of some kind produced by the liberation of nascent oxygen on the positive conductor, due to the electrolytic action of the current on the water, with which the goods are saturated, and which oxide enters into the goods or the fibres of the goods aided by the current, and probably is combined, partly chemically and partly mechanically, with the fibres, thereby making the same waterproof or water-repllent by the presence of the oxide in or on the fibres or in or on the goods. The strength of the current applied will depend upon the character of the goods submitted to treatment. Satisfactory results have been produced with cotton cloth, using one volt, and also with 100 volts, the period of treatment being shortened by the increased voltage. Voltages have likewise been used between these two extreme limits, and have had most satisfactory results with small conductors, say plates two inches in diameter, using a current of 30 volts.

Each specific piece of goods offers a different resistance to the passage of the current when in a wet condition, and different goods require different strengths of current. The theory of the process, as it is understood, is that the water absorbed by the fibres or the goods is electrolyzed by the action of the current, nascent oxygen is produced on the metal plate or roller on the positive side of the goods, and which is connected with the negative pole of the battery or dynamo (or that which furnishes the positive current), and nascent hydrogen is liberated on the negative plate or roller (which is connected to the positive element). The nascent oxygen acts on the metal plate or roller on the positive side of the goods, forming some oxide of this metal. This oxide is carried into or onto the fibres in the direction of the flow of the current, combining, probably, with the goods or fibres of the goods, and forming with or on the fibres a product which renders the various fibres composing the goods, and thus the goods themselves, waterproof or water-repellent. It is not known for certain whether the oxide is mechanically or chemically combined with the fibres, but it is believed that both effects are obtained. The nascent hydrogen on the negative side will, if the time of treatment is too long, accumulate and then begin to act as a reducing agent, and in case the period of treatment is prolonged beyond the proper time then the nascent hydrogen will reduce the oxide of the metal in or on the goods to the metallic state and the combinations or union of the oxide with the fibres will be destroyed by the reduction of the oxide to a metallic state.

It is very advantageous to place a sheet of fabric, such as cotton cloth, around the roller or on the plate on the negative side. By the use of this fabric the evolved hydrogen is mechanically kept from affecting rapidly the oxide in the cloth to be waterproofed, which latter is placed between this sheet of fabric and the plate or roller on the positive side of the goods; and in this way the period of treatment may be prolonged and the operation rendered less delicate, and such exactness is not then required as to time, and the general result is improved. This sheet of fabric may be continuously used until it is worn out, and if, at any time it is dried, is found not to be waterproofed. The fabric treated should have only a sufficient amount of oxide in it to make it waterproof. The proper strength of current varies with each specific material, its thickness, the time the treatment is to occupy, and the amount of pressure exerted on the goods by the conductors. The different metals require a different treatment as to time with the same current and pressure. While aluminum, tin, zinc, or those metals in general which do not stain white cloth noticeably, are to be used when the waterproofing effect only is used, for staining or dyeing the fabric metals such as copper, iron, silver, etc., are to be preferred. Such metals as copper or iron may, however, be used even when the sole purpose is to waterproof the cloth, provided it is colored cloth, and the alteration in color, due to the treatment by these metals, is not considered objectionable. Lead is not as serviceable for waterproofing as aluminum or tin, although it allows of the passage of a great quantity of current. Zinc gives fairly good results.

The degree of pressure to which the goods should be subjected may vary within very large limits; but it is always advantageous to have firm contact, such as would be obtained from a screw-press or a lever. With rollers the pressure should be regulated by bringing them forcibly together by springs and a screw or screws, so that the goods shall be in forcible contact with the conductors at all points where the current is passing. As to the amount of moisture to be employed, the goods should be thoroughly wet, though the desired result can be obtained with the goods in a damp condition. This process has the great merit of making the separate individual fibres and threads water-repellent, while the pores of the goods are in no way stopped up or closed. Consequently, if used on clothing, it

would not prevent evaporation taking place through the interstices between the threads.

Besides practicing the process on cotton, linen, woolen, and silk fibres, it is proposed also to apply it to string, sails of ships, sewing thread, and the like, treating such material as they pass over a conducting-roller and between a conducting-roller and one or more aluminum or tin rollers, preferably, on the positive side. Goods thoroughly waterproofed by this process will withstand considerable washing, particularly if the water is not too hot.

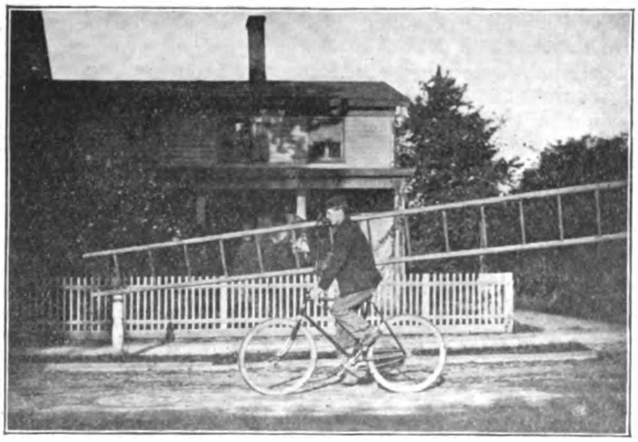
The above process has been patented in the United States and a company, called "The Electro-Waterproofing and Dye Fixing Co.," has been organized by some very prominent business men and financiers, who are now building some large machinery for commercially applying the process. We have ourselves witnessed some interesting tests with material thus waterproofed.

ELECTRIC LIGHTING

Harrison's Record-Breaking Lamp Inspection on the Bicycle.

IRVING HARRISON is a street-light inspector for the Hackensack Gas & Electric Co., of Hackensack, N. J. About two years ago he made his rounds with a horse and buggy. During April, 1896, he learned to ride the wheel and for more than a year has traveled over the route on his bicycle, falling back on the horse and buggy only after hard storms. His route of inspection covers a territory of about 50 miles, and includes the towns of Hackensack, Teaneck, Leonia, Maywood and Fairmount. He is required to cover this route daily and sometimes twice a day.

Mr. Harrison has traveled over 36,000 miles since April, 1896, up to December 31, 1897. Nearly all of this distance has been made while inspecting his lines. During the early part of 1897 he averaged 45 miles a day. In March he joined the Hackensack Wheelmen's Club, and at once entered the club's mileage competition. It was while riding in this contest that Harrison



HARRISON ON HIS LAMP INSPECTION TOUR.

started out to make a State record. He then began to run up the miles, and at midnight, December 31, had the satisfaction of beating the 1896 national record, 22,848 miles, with a grand total of 26,252 miles.

Harrison was greatly handicapped while covering a large proportion of the distance. Part of the time he was compelled to carry an 18-foot ladder on one shoulder and steady himself with his left hand. Other times he would cover mile after mile with a pair of climbers strapped to his legs.

The Century Road Club of America have recently published the list of contestants in the mileage competition. John H. George, of Philadelphia, takes the American record with 32,479 miles; Harrison has the New Jersey record with 26,252 miles.

Harrison's feat is more creditable than Mr. George's, as the latter had the assistance of a fellow rider on a tandem from July 1 till December 31, while Harrison made all his miles on a single wheel, had a ladder, climbers and lamp to carry, and had from eight to fifteen hills to surmount daily, as follows: To inspect Maywood, two going, one returning; Teaneck and Leonia, three going, two returning, including the famous breakneck Fort Lee hill. When the second trip would be made the lights on this hill were skipped.

Harrison holds the Hackensack Wheelmen's Club record for eight months (March 1 to November 1), with a grand total of 15,783 miles. He expects to establish a new club record for 1898. Every electric light man will wish him success, and even if they do not ride wheels all of them watch his progress with interest. It is only justice to add that the wheel ridden by Mr. Harrison is a No. 9 Crescent, made by the Western Wheel Works, of Chicago.

Phase Equipment of the New Consolidated Station of the Buffalo General Electric Company.

THERE is perhaps no topic of more general interest to the electrical engineer of America, and no achievement of which he is more justly proud, than the transmission of the current generated at Niagara to the city of Buffalo. Every new application of Niagara's current, every improvement in its mode of transmission and conversion, is watched with the keenest interest, and it therefore affords us great pleasure to be able to present to our readers to-day, through the kindness of Mr. Henry G. Stott, engineer of the company, full data regarding the equipment of the new consolidated station of the Buffalo General Electric Company, of Buffalo, N. Y., of which Mr. C. R. Huntley is the well-known general manager.

It has been practically decided that the new station, which will be built, will be upon the site of the old Wilkeson street station, on Wilkeson, Staats and Mohawk streets, where the company own a lot and old buildings covering 250 feet by 150 feet. At present two stations are running—Elk street and Court street—but both of these will be consolidated into the new station. Work will be begun immediately upon the buildings and pushed to an early completion, as the contracts for the machinery call for its delivery within three months. Eleven transformers of 250 k. w. each, stepping down from 11,000 or 22,000 volts to 352 volts, will be installed in the transformer house which will be built beside the new station. The voltage of 352 was adopted as a standard as being suitable for use in three-phase rotary transformers to convert to 550 volts direct current, as a very large business is anticipated in this current, 1,000 h. p. additional being expected in the first year. This voltage also lends itself to the use of synchronous motors of the revolving field type and frequency changers, without necessitating large collector rings and brushes, as the revolving fields only take from 10 to 25 amperes of 110 volts d. c.

The following apparatus have been ordered from the General Electric Company to begin the work with: Six 150 k. w. three-phase, 352 volt synchronous motors; rotary field type, to drive Brush 125 light arc machines. Twelve No. 12 Brush two-circuit, 9.5 amperes, 125 light, arc machines, two dynamos direct coupled to each synchronous motor, arc machines to have new automatic regulator, doing away with wall controllers, and making each machine self-contained. Eventually there will be 12 motors and 24 arc machines of this type. Two 200 k. w. rotary transformers from 352 volts, three-phase a. c. to 550 volts d. c. It is the intention to add to this as soon as the first two are filled up with 400 k. w. units. Three frequency changers, 400 k. w. each, to change from 25 cycles to 62½ cycles. These frequency changers consist of a 240 k. w. synchronous motor direct coupled to an alternator armature wound for 2,200 volts, this armature rotating in fields similar to those of an induction motor to which 25 cycle three-phase current at 352 volts is supplied.

The synchronous motor will drive this armature at 375 revolutions per minute, and as the fields of the alternator part have 12 poles, this will give a frequency of 4,500 per minute, and this, added to the 3,000 due to the Niagara generators, gives a total of 7,500 per minute, or 62½ per second; the synchronous motor of course driving the alternator against its inclination as an induction motor. The efficiency of these large combination sets or frequency changers is remarkably high, being from the 25 cycles to the 62½ cycles, 88 per cent. Switchboards are now being laid out at Buffalo and will be built by the General Electric Company when the designs are completed.

To provide for possible interruption, due to a breakdown in

the cable, duplicate cables will be run from Niagara Falls, and both will remain in use until some accident occurs to one, when an automatic circuit breaker, designed by Mr. Emmet, will throw out the faulty cable. This circuit breaker is entirely novel in design and will be operated by a small induction motor. They will be placed at both ends of the line.

Three-Phase Factory Transmission for the W. W. Kimball Co., Chicago.

MUCH has been said in the past few years about the advantages of multiphase motors, but it is doubtful whether the electrical engineer who has dealt always with direct current apparatus actually realizes the simplicity of a multiphase shop transmission system. To those who are skeptical about the merits of a three-phase shop installation a visit to the piano and organ factory of the W. W. Kimball Co., at Chicago, is to be recommended. No one who inspects the plant in service there can fail to be impressed with the suitability of multiphase apparatus to a shop transmission where it is desirable to have a number of motors operating with no attention paid to them beyond the usual oiling and superficial cleaning that machinery around a factory commonly receives.

The W. W. Kimball Co. is known the country over as large manufacturers of pianos and organs. Their factories are located at Twenty-sixth and Rockwell streets, Chicago. The consulting electrical engineer of the concern is Mr. F. D. Mack, who planned the present electrical installation, and who takes pride in being the first to put in operation in the West a large factory transmission using motors having no armature contacts and nothing which can lead to the starting of a motor hospital for the repair of commutators or collector rings.

At present only part of the factory is electrically driven, but the writer is informed that electric drive will very soon be used throughout the entire factory.

The electrical part of the power plant now consists of a 180 kilowatt three-phase Westinghouse alternator belted to an Allis Corliss engine. This plant is to be enlarged, however, by the addition of a direct connected alternator of 300 kilowatts capacity driven by a vertical Corliss engine at 100 revolutions per minute and having 72 field poles. The frequency employed in this plant is 60 cycles per second, or 7,200 alternations per minute. The generator now running is rated at 180 kilowatts at 400 volts, but the field strength has been increased so as to make the voltage at the switchboard 440. This was done to permit the use of standard apparatus for the lighting part of the system. Transformers are regularly made which will reduce from 400 to 100 volts. The factory was already lit with 110-volt lamps, so in order to continue the use of 110-volt lamps the generator voltage was raised to 440 to make the 4 to 1 transformers give 110 volts on their secondaries. The generator fields are excited by a small compound-wound direct current dynamo, and in addition to this have a set of coils supplied by a rectified current from an auxiliary winding of the armature which perform the same function as the series coils on a direct current compound-wound dynamo, viz., to prevent drop in voltage as the load is increased. The current for these compensating field coils is generated in a few turns of what may be called secondary windings of the armature. The stronger the current in the main armature coils the stronger the current in this secondary winding. This secondary current is led to a rectifier at the end of the shaft and from the rectifier brushes to the fields. The voltage of this current being low, there is little trouble from sparking at the rectifier.

From the generator the three main cables run to the switchboard, where are three ammeters, one for each leg of the circuit, and a voltmeter on one of the three sides. These ammeters, of course, are somewhat deceiving to an ordinary attendant, as they indicate wattless current as well as the actual working current, when there is an inductive load such as motors, and it is contemplated to replace them by indicating wattmeters in each lead so that the actual work being done can be seen any time without guesswork.

From the switchboard one set of feeders is run for power and another for lights, each being provided with fuses and a three-pole switch. The lights are turned off at the switchboard during the day. The feeders run to centers of distribution where each branch is fused to the full capacity of the wire. The fuses at the switchboard and distribution centers are the only ones in use. For running from one building to another the wires are bunched together to avoid induction, and run in a single lead covered cable in drain tile, underground.

It is when one reaches the motors that the beautiful simplicity of the multiphase system begins to be most evident. Those in use in this factory are the Westinghouse three-phase constant speed type having no commutators, brushes, collecting rings or moving contacts of any kind. The three leads are connected to the stationary field windings which are placed in slots in the field ring surrounding the armature, and which form the primary coil, while the revolving armature with its winding of copper bars, short circuited at the ends, forms the secondary coil. The field windings being embedded and the armature an indestructible mass of iron and copper, there is nothing about the motor to suffer from neglect, save the bearings, and any mechanic knows how to oil bearings. For gradual starting of a motor an auto-converter is used. It is operated by a double-throw four-pole switch. To start a motor this switch is thrown down until the motor gains a little speed and then is thrown up into running position. The rush of current through these induction motors is so small at the start, however, that Mr. Mack thinks even the auto-converter, as simple as it is, not necessary on motors of less than 20 horse-power. It is the custom in this factory to start all the motors at once at the time the generator is started, which still further adds to the simplicity of the system. With a separately excited alternator this is easily done, while it would be difficult with a self-excited direct current generator. It may be said here that when the two generators are in operation they will be operated in parallel. They can be thrown in parallel at speed or started up together in parallel and the whole factory started with them.

That it is difficult to injure an induction motor goes without saying. These motors are not rated according to heating limit, but according to the point at which the efficiency begins to fall off considerably, which point is somewhat under the heating limit of the primary winding. The point of highest efficiency is between half and full rated load.

In tests to which Mr. Mack has subjected these motors they have started from rest with a torque two and one-half times the full rated load running torque and with 15 per cent. overload has reduced speed 5 per cent.

Another test which was not on the programme was made one day when the box on a new motor got so hot it melted the babbit and let the armature down on the fields. The motor ran this way for some time, in addition to pulling a shop load, before it was discovered. The motor stopped instantly when the current was shut off, and it took hydraulic pressure to get the box off the shaft, but the motor was in operation again in a few hours, and has been running ever since.

There are now in the factory eleven three-phase motors of from 40 to ½ horse-power, running short lengths of shafting in the different scattered departments and freight elevators, and there are 300 incandescent lamps in the shops.

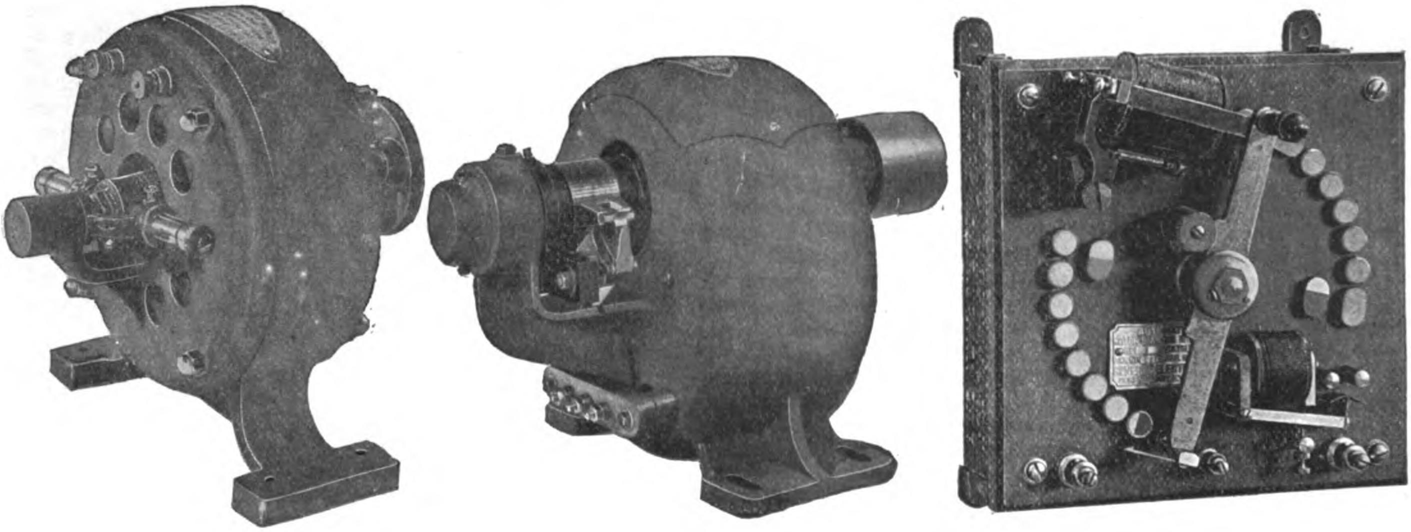
The complete electric driving of the shops will call for six more motors of 50 to 30 horse-power and three more 7½ horse-power elevator motors. Six hundred lights will also be added. The old steam plant will be abandoned for power purposes and used for heating and kiln drying. Power will all be generated in the new power plant in which the 180 kilowatt alternator mentioned is already running.

This plant is but the forerunner of many more of the kind that will go in when the simplicity of the multiphase motor for certain kinds of shop work is more fully appreciated. In fact, a number of similar installations are now under way in the West. The motors in the Kimball factory are most of them bolted to the ceiling out of the way, and practically need no more attention than the shafting to which they are belted. The dust of the shops has no effect on them, and they have no more points of weakness than any machine having two bearings. When this point has been reached in the development of a shop driving motor it is hard to see what further advance can be made in the way of ease of maintenance.

G. E. Direct Current Small Motors.

THE GENERAL ELECTRIC COMPANY announces in a recent bulletin a new line of well designed and thoroughly constructed direct current motors of small capacity adapted to the direct application of power to small machines of all kinds. They have been given the designation of "Type C A," and in their design the production of an efficient motor, sufficiently light and compact to allow of installation in cases where space is limited and absolutely rigid support unobtainable has been kept constantly in view. A magnetic circuit, therefore, entirely of laminated iron has been adopted, and greater lightness and compactness thus secured than would have been possible with cast iron. Furthermore, by the use of laminated iron a uniform magnetic circuit is insured.

High grade material is used exclusively throughout these motors, and the workmanship is the best. The construction of the armature, commutator and field coils follows closely that in the standard General Electric railway motors. Indeed every feature of excellence of the latter has been retained in the "C A" type. The laminated armature core is toothed and wound with the Eickemeyer type of coil. The leads from the armature are soldered directly into slots in the segments and the field coils are thoroughly taped and mounted on laminated pole pieces. The armature can be withdrawn after taking off the pulley end bearing, and the field coils removed through an opening in the frame. In the larger machines the shaft is mounted on two similar swivel bearings each self-oiling. The brush holders are adjustable radially, and may be revolved around the commutator if required. The neutral point is very wide, however, and no adjustment of the brush holder is necessary. These motors are enclosed and thoroughly protected from mechanical injury, but thorough ventilation is provided by holes in the bottom of the case and around the commutator end of the armature. Should these motors be used in places where flying dust necessitates extra protection, the commutator and brush holders may also be encased.



FIGS. 1, 2 AND 3.—G. E. DIRECT CURRENT SMALL MOTORS.

The speeds are lower than usual with motors of small capacity. Better provision for overload is thus given and losses are not so great. The regulation, efficiency and disposition of the material in the "C A" motors also combine to give them a continued high economy. Heating tests show that they will run continuously with but slight increase in temperature, and even with a momentary overload of 100 per cent. little or no sparking is noticeable. In cases where a number of these motors are required to meet special conditions, the standard construction and wiring is susceptible of modification.

No rails are necessary with this motor. The belt is tightened by moving the motor on the lag screws, which pass through elongated holes in the feet of the frame and hold the motor in place.

One feature of advantage which this motor has is the possibility of placing it in almost any position with no greater change than the turning of the bearings to suit the position selected. The "C A" motor may be installed on the floor or be suspended from the ceiling, be set on a shelf or attached to a wall. In every case the oil cellar is at the bottom of the bearing.

The 1 h. p. and ½ h. p. "C A" motors are designed for 115, 230 and 500 volt circuits, the ⅛ h. p. for 115 volt circuits. The floor space for the first named is only 22⅛ inches by 16½ inches, and for the ½ h. p. motor 18¾ inches by 13 inches. The motors are finished in black with brush holders and small parts nickeled and polished.

For use with the two larger sizes a new type of rheostat has been developed. It is provided with an automatic switch which breaks the circuit in case of overload and effectually protects the motor armature. The smaller sizes are series wound and require no rheostat.

Of the accompanying engraving Fig. 1 shows the ½ and 1 h. p. type above described, and Fig. 2 the ⅛ h. p. machine. The rheostat is shown in Fig. 3.

Two Phase Power Transmission Apparatus for St. Joseph, Mo., Stock Yards.

ELECTRICAL power transmission is becoming justly popular around large stock yards and packing houses. Armour & Company, at the Chicago stock yards, began to use electric motors around their plant several years ago, and have been constantly adding to their list of electric motors. The scattered nature of the work in stock yards makes electric power transmission far superior to long lines of steam pipe or shafting.

The two great Western packing firms of Swift & Company and Nelson Morris & Company are building new plants at St. Joseph, Mo., and it is interesting to note that both these plants will be equipped with two-phase alternating lighting and power apparatus.

The generating plant for Swift & Company will comprise one 250 kilowatt and one 800 kilowatt, two-phase, 220 volt, Westinghouse generator. Contracts have also been closed for forty-nine constant speed, two-phase Westinghouse motors of various sizes. The switchboard will be equipped with both wattmeters and ammeters. What few lamps are necessary will be run at 110 volts, the pressure being reduced from 220 volts by a Westinghouse auto-converter. This auto-converter is a converter in which there is no secondary coil, the reduction in pressure from 220 to 110 volts being brought about by connecting the lamp circuit so as to get only half the pressure supplied to the primary coil, or, in other words, so that it gets the effect of only half the number of turns in the coil. The efficiency of the auto-converter is about the same as that of a regular converter with primary and secondary coils. Its advantage is simplicity in construction due to having only one coil instead of two.

Nelson Morris & Company will put in 440-volt two-phase Westinghouse generators, one of 120 kilowatts and another of 50 kilowatts. There will be at first in this plant some twenty two-phase motors of from three to forty horse-power, some of which will be of variable speed and some of constant speed. The switchboard at this plant will also have both wattmeters and ammeters.

Niagara Power In Canada.

A special dispatch from Niagara Falls of February 5 says: The Canadian Niagara Power Company is getting in a quantity of machinery for the purpose of supplying its customers on the Canadian side of the river. This machinery will be placed in the power house of the Niagara Falls Park & River Railway, and it is expected that it will be all installed by the first of May next. Some of it will be made by the Royal Electric Company, of Montreal. The Westinghouse Electric and Manufacturing Company, of Boston, is now building two alternating current generators for the company. They will be completed and put into operation some time in May. When these machines are in operation they will produce 1,000 h. p.

So far the Canadian Niagara Power Company has received no application for power. Advertisements have been inserted in the Toronto and Hamilton papers, but there have been no returns. The company at present is prepared to deliver 500 h. p. to any one applying for power within a radius of four miles of the power house of the railway company, which is situated in the Queen Victoria Park.

Electric Hoists in a Maine Line Quarry.

A NEW design of electric hoist and cable way, manufactured by the Lidgerwood Manufacturing Company, New York, has just been completed at the lime quarry of the S. E. & H. L. Shepherd Co., Rockport, Me. The hoist is equipped with two G. E. 1,200, 500-volt General Electric railway motors, controlled by General Electric K 11 controller. The apparatus is built for lifting a load of ten tons; the average load hoisted is four tons. The power is obtained from the railroad circuit and is sold by the Knox Gas and Electric Company at four cents per horse power. This is considered very much cheaper than steam power as the labor and the wear and tear are reduced to the minimum. The series parallel controller is also a great power-saver. The hoist is capable of hoisting 2,000 casks of lime rock per day. The cable way is 700 feet long and is suspended from two very substantial towers, one 55 feet high and the other, the main hoisting tower, 65 feet high.

This hoisting plant is considered the finest in the country. It is the third plant in Knox County, Maine, that has adopted electricity in preference to steam for hoisting, all using the General Electric 500-volt railway motors with series parallel control.

The Proposed Power Plant at Helena, Mont.

The upper Missouri, or that part of it below Canyon Ferry, has been dry on account of the dam which has just been completed by the Helena Water and Electric Power Company, seventeen miles north of Helena. Although the river at that point runs more than 4,000 cubic feet per second, according to the Government surveys, it took the river two days to raise its level the five feet remaining before it flowed over the dam.

A lake is being formed by the backwater of the dam, which extends seven miles up the river and covers six square miles. Meantime the river below the dam was practically dry, a child being able to ford it without danger. Men prospected in the river bed for gold, while others have taken out large catches of trout and other fish that have been left in the pools formed in the river bed.

The dam is thirty-four feet high and has been built at a cost of $450,000. It is for furnishing electrical power to Helena.

Another Chicago Electric Elevated.

The Chicago City Railway Transit Company, just incorporated for $1,000,000, is an adjunct of the Chicago City Railway Company. It proposes to build an elevated railway in Dearborn street from the river to Thirty-ninth street, at least, which will be a rival to the South Side (Alley) Elevated.

The structure proposed is of the lattice kind, so as not to obstruct the light, as other lines' roads do.

CHICAGO, ILL.—The Electro Medical Manufacturing Company has been formed; capital stock, $2,500; incorporators, C. O. Lindstrom, A. N. Lindstrom and O. B. Hjorth.

LITERATURE

A POCKET DICTIONARY OF ELECTRICAL WORDS, TERMS AND PHRASES. By Edwin J. Houston, Ph.D., New York, 1898. American Technical Book Company. 945 pp. 3½ x 6½ in. Price, cloth, $2.50; leather, gilt edges, $3.

Prof. Houston's dictionary is too well-known to require any extended notice at this late day. It is sufficient to say that it has long enjoyed a well-deserved reputation. In the efforts to bring it up to date, it has been found that the growth of the art and its terminology has been so great that the number of new words, terms and phrase greatly exceeded those in the original dictionary with its appendix. To meet this difficulty and to economize space it was decided to adopt concise definitions and to omit all encyclopedic matter.

The new pocket edition contains no fewer than 11,000 words and 15,000 definitions; this is no mean vocabulary for a comparatively young science, and shows at what rate the coinage of words and terms is going on in the electrical arts.

Being a condensation, and space being valuable, all illustrations have been omitted; this, in our opinion, detracts very little from the value of the work, intended as it is to be an epitome of its larger prototype.

The handy size of this new edition gives it a special value.

ANNUAIRE DE L'OBSERVATOIRE MUNICIPAL DE MONTSOURIS pour l'an 1898. Paris. Gauthiers Villars et Fils. 636 pp. 3½ x 6 in. Paper. Price, $1.

This annual gives the record of the work of the Montsouris Observatory in Paris, which is devoted not only to meteorology, but also to chemistry, micrography and hygiene applications.

FORMULAIRE DE L'ELECTRICIEN. 15th year, 1897. By E. Hospitalier. Paris. Masson & Co. 424 pp. Pocket size. Price, $2.

This excellent compendium continues to increase in value with each succeeding year. It contains some matter not to be found in any other book of its kind that we know, and the careful arrangement adopted as well as the judgment shown in its selection are admirable. We notice a new and valuable feature added to this year's edition consisting of a technical vocabulary giving the principal electrical terms in French, English and German.

NEWS AND NOTES

A Double Commutator Dynamo Supplying a Three-Wire System.

FOR small isolated plants wired for the three-wire system the double-wound, double commutator dynamo is coming into favor as being more efficient, less bulky and cheaper to maintain that two 110-volt machines.

Slack's immense grocery store at 45 Randolph street, Chicago, is now being supplied with light and power from an isolated plant in the basement, which has only one dynamo for supplying the two sides of the three-wire system with which the building is wired. The machine is a Churchward multipolar, built by the Excelsior Electric Co. It has two sets of armature windings on the same core and two commutators, one on each end of the shaft. Each winding generates 110 volts, and the two sides of the machine, that is, the two commutators, are connected in series, running the 220-volt three-wire system just as if there were two separate dynamos. The advantages of the three-wire system are thus obtained without the expense of maintaining and running two smaller machines. The building can be supplied either from the isolated plant or the Edison Company's street mains. The isolated plant is run during times when there is a good load to carry and the balance of the time the building is switched on to the Edison mains.

The dynamo is rated at 250 volts, 400 amperes, and is belted direct to an Allis Corliss engine running 90 revolutions per minute. The fields are compound-wound. An ammeter is kept in one armature circuit and the voltmeter on the board has a double throw switch with which it can be connected to either side of the circuit. The machine runs perfectly sparkless and regulates so well that the running of an elevator does not make any perceptible variation in the lamps.

The store is wired for 2,000 lights, and is one of the most brilliantly illuminated buildings in Chicago. Besides the lights there are three motors in the building, one of 10 horse-power running a freight elevator, one of 8 horse power belted to a shaft driving fans, and one of 10 horse power belted to a shaft from which coffee grinders and the air compressor for the cash carrier system are driven. This latter shaft is usually driven by belt from the engine, and the motor is for use in emergencies and when the engine is not running. Mr. F. D. Mack was consulting engineer for the installation.

Is the Welsbach on the Wane?

Reports reach us from the different manufacturing and illuminating companies of the waning popularity of the Welsbach burner, as proved by the accounts of the illuminating companies in whose territories the mantle burner at first made some headway. Any customers lost are returning to the incandescent lamp, tired of the expense involved in renewing shattered mantles, and worn out with the ghastliness of the light. Additional proof is furnished by the production and sales reports of the different manufacturing companies, which show a constantly increasing demand for incandescent lamps, as well as for arc lamps, especially those of the enclosed arc type. In stores, restaurants, cafes, hotels and halls where the Welsbach burner secured temporary success, the enclosed arc lamp is rapidly bringing back the use of electricity, while in new establishments the Welsbach burner is not finding much foothold.

Electric Shock Given to Speed Race Horses.

According to a New Orleans report, another attempt has been made to use electricity for the speeding of race horses by shockingly appealing to their horse sense. The practice, besides being fraudulent, is certainly unsportsmanlike, and is generally stopped by the exposure and punishment of the offenders. The details of the latest affair are given as follows: Another attempt to use an electric device for nefarious purposes was brought to light yesterday afternoon when an imitation lead pad, containing a battery, was found in the possession of one E. R. Rodgers, owner of Blacking Brush and other platers of that caliber. Secretary Clark had been on the alert for the past week, as there were rumors that a new device in that line was to be sprung on the officials at the Fair grounds. After a diligent search he discovered the lead pad in question in the stable of E. R. Rodgers. The pad was one of the ordinary kind, with mercury cells instead of lead plates in the pockets. There were three batteries on each side, connected with a wire which ran up to the top of the pad, and also with two copper plates which were on the inside at the bottom. When the jockey leaned forward on the saddle over the pad he pressed the button and so turned the current on. An annunciator in one of the pockets of the pad told when the current was on. Several parties were mixed up in the affair and the board of stewards are making a thorough investigation of the matter. Sufficient evidence has been obtained against three of them to warrant the officials in taking action in their cases. There have been several attempts in the past to use devices of this kind, but through the alertness of Secretary Clark they have been nipped in the bud.

A Big New Station For New York.

The Edison Electric Illuminating Company is rumored to have purchased from William L. and Benjamin Peck the block of twenty-two lots bounded by Thirty-eight and Thirty-ninth streets, First avenue, and the East River, New York City, for $345,000. The transaction was negotiated by B. W. Williams, Jr. It is said that the company will erect on the plot the finest and largest electric plant in the country.

BOSTON, MASS.—A bill has been introduced in the Massachusetts Legislature for supervision of telephone rates and service by the Board of Gas and Electric Light Commissioners.

LEGAL NOTES

The Decision as to Joint Use of Tracks.

The first decision in a street railroad case, based on the Kingston, N. Y., traffic decision, was handed down last week by Justice Wilmot M. Smith, in the Supreme Court, in Brooklyn. In the case of Kunz vs. the Brooklyn Heights Railroad Company, the plaintiff sought to enjoin the defendant from making connections with the Nassau Electric Railroad and the Smith street line and operating cars over the tracks of those roads. The contract makes the operation of Brooklyn Heights cars over the other companies' tracks a part of the consideration.

The defendant claims the right to operate its cars over the tracks of the other two companies and the curve without the consent of property owners and local authorities, by virtue of a traffic contract made between the three companies. Justice Smith says that until recently the right to make such contract was considered to be settled. He cites the People vs. Brooklyn, Flatbush and Coney Island Railroad Company, 89 N. Y., 75, and Ingersoll vs. Nassau Railroad, 89 Hun., 213, and says that they are conclusive of the right of the contracting companies to operate their cars over the lines of each other without new consents, unless these decisions were overruled by the decision of the Court of Appeals.

He then examines the case of the Colonial City Traction Company vs. Kingston City Railroad Company, 153 N. Y., 548, and 154 N. Y., 493, better known as the Kingston case. One company sought to condemn the right to use the tracks of another under Section 102 of the Railroad law, in order to connect and make a continuous route. The Court held that the plaintiff had no standing in court until it first obtained the consents of the property owners along the route. "The remark," says Justice Smith, "by the learned Judge who wrote the opinion that the consents of the property owners would be necessary even if the one company consented that the tracks be used by the other company, was obviously a dictum of the Judge, as he himself clearly intimated in writing the opinion upon the motion for a reargument, 154 N. Y., 493."

The opinion concludes as follows: "I therefore conclude that the decisions in the People vs. Brooklyn, Flatbush and Coney Island Railroad Company, 89 N. Y., 75, and Ingersoll vs. Nassau Railroad Company, 89 Hun., 213, have not been overruled, and are binding on this Court."

The Sprague Motor Suspension Patent.

We are in receipt of the following note from the General Electric Company:

The decision in the case of the Sprague Electric Railway and Motor Co. vs. the Union Railway Company and the Walker Company is of considerable importance. As the claims of the Sprague patent have been sustained by the court they cover the mounting of electric motors whose armatures are carried by the field magnet (and not concentrically by the driven axle) by sleeving extensions or arms from the field magnets of the motors upon the driven axle, and flexibly supporting the other end of the field magnet by a spring or flexible connection from the truck or car body.

Sprague's construction simplified the earlier methods of mounting, in which the motors were mounted upon a special supporting frame or platform which was an integral portion of the truck. In Sprague's case the field magnets themselves carry the armature and are directly clamped at one end to the driven axle and spring hung from the truck at the opposite end. The motor became thus for the first time readily detachable, and its mounting much more compact and simple than before.

An injunction has been issued against the Walker Company, and an appeal has been taken from Judge Wheeler's decision, but the court refused to suspend the injunction against the Walker Company, although it allowed the Union Railway Company to continue to run the ten motors it had already in use, but it prohibited them from purchasing any more.

An accounting has also been ordered to be made by both defendants.

National Conduit and Cable Company Wants a Mortgage Made by Eastern Electric Company Set Aside.

The National Conduit and Cable Company, of New York, has instituted suit in the Circuit Court at Baltimore to set aside a mortgage executed by the Eastern Electric Company, of Baltimore, to the United States Trust and Deposit Company, of Baltimore, and to have canceled all bonds issued under the mortgage.

The bill of complaint was filed by Thos. M. Lanahan and Frank Gosnell, attorneys. It states that the mortgage was executed July 15, 1897, and covers all the property and franchises of the Eastern Company. The mortgage, it is alleged, is void, as to the creditors of the company, because the stockholders never authorized its execution.

The whole issue of bonds, it is asserted, were delivered to Wm. I. Atkinson, an employé of the company, who has left the State, and none of them are in the hands of bona fide purchasers for value. Coupons on the bonds are about maturing, and the complainant is apprehensive that they may be paid by the company or its receivers. The claim of the New York company is $5,106.22.

Accident From Furious Speed of a Car in Brooklyn.

William Walsh, in his suit again the Atlantic Avenue Railroad Company, of Brooklyn, stated in his complaint that while he was driving a dirt cart out of a cellar upon a street, he looked to see if any car was coming, and saw none; but that when he was about on the track, a car approached at a furious rate of speed, to avoid which he immediately turned his horses round, and by reason of their perilous position the horses shied, throwing the wagon against the curb and precipitating him from his seat to the ground. Judgment secured by the plaintiff on the trial was affirmed by the Second Appellate Division, which held, by Presiding Justice Goodrich, that plaintiff's evidence that the car struck the hind wheel of his wagon, that his horses went off of their feet, and hit the forward part of the wheel of the wagon against the curb and threw him off, was competent, within the pleadings, upon the question whether the furious rate of speed of the car, coupled with the attempt of the plaintiff to get out of the way, caused the accident. The Court's charge that if the plaintiff looked, and there was no car in sight when he drove into the street, he could not be charged with negligence, was proper, there being a distance of sixty-five feet from the place at which he came upon the street to the corner around which the car came.

Sick Passengers on Cars.

A rule as to sick passengers on street railway cars has recently been laid down by the Appellate Division of the Supreme Court in the Fourth Department, speaking through Mr. Justice Adams. The plaintiff, who was a passenger on one of the Buffalo trolley cars, having paid his fare, took a position on the rear platform. The conductor called his attention to the fact that the rules of the company forbade him to allow passengers to stand there, but the plaintiff insisted upon remaining where he was, because he was suffering from nausea and was afraid he should vomit. Thereupon the conductor ejected the plaintiff from the car, using no more force than was necessary. A majority of the Appellate Division held that the conductor did right as matter of law, but Mr. Justice Green delivered a strong dissenting opinion, in which Judge Hamilton Ward concurred. They thought that the question whether the enforcement of the rule against the plaintiff was reasonable or not was a question of fact to be determined by a jury. "The place selected by the passenger," said Judge Green, "neither annoyed nor inconvenienced any one, and he should have been allowed his temporary purpose of gaining relief from his illness, and avoiding the discomfort which might have resulted to the other passengers had he remained in his seat." In the view of the minority of the court, the act of the conductor was in disregard of decency, humanity, and common civility. It seems to us that the minority forgot the rights of the other passengers, whom the conductor was there to protect, and who have a right to object to travel with men whose drink is too strong for their stomachs.

OBITUARY

John E. Ridall.

We regret to note the death of Mr. John E. Ridall, one of the electric lighting pioneers, of Pittsburg, Pa., who has just been carried off by pneumonia at the age of 48. He started in life a poor boy on the Mississippi river on the "Great Republic," which ran between St. Louis and New Orleans. He soon left the river and entered the Allegheny National Bank at the age of 19. He went from there into the United States Bank, a new organization, of which he was made cashier. In 1880, with Eugene Ingold, he formed the firm of Ridall & Ingold and went into the electric light business as agents of the Brush Electric Company, of Cleveland, for which he was general agent at the time of his death. He was connected with the Allegheny Electric Light Company and had just been re-elected to a directorship in that company. He was elected secretary a few weeks ago of the newly organized Charleroi Brewing Company. He was a member of the St. John's lodge, F. and A. M., and a member of the Duquesne and Americus Republican clubs. He was married in 1872 to Mary B. Love, who has been dead some years. Four sons and one daughter survive.

SOCIETY & CLUB NOTES

New York Electrical Society.—Electricity From Coal.

A very interesting meeting of the New York Electrical Society was held on February 11 at the College of the City of New York, in association with the New York Section of the American Chemical Society. Dr. C. E. Emery presided. An illustrated paper was given by Mr. Joseph Wetzler on "Electricity Direct From Coal," which was discussed by Dr. McMurtrie, Prof. Loeb, Messrs. Essick, Mailloux, Osterberg, and others. About 150 were present, and Secretary Guy announced the names of 19 new members, who were duly elected. It had been hoped to have present Prof. G. F. Barker and Dr. Edgar Smith to discuss some aspects of electro-chemistry, but these gentlemen will appear later before the two societies.

Speeches Over Telephone.

Over the long distance telephone sixty persons who were entertained last week in the United States Hotel, in Boston, by the Electric Club of that city heard speeches delivered by Colonel A. B. Chandler, president of the Postal Telegraph Company, at his home in Clinton avenue, Brooklyn, and Charles P. Bruch, secretary of the Postal Telegraph-Cable Company, in his office in the Postal Telegraph Building. Each of the guests had a receiver placed near him on the table. The experiment was very successful, transmission over the Postal wires being excellent.

Am. Paper & Pulp Association

The annual meeting of the above Association will be held at the Hotel Waldorf-Astoria, February 16 and 17. Among papers to be read are two upon electric power in paper making, by Dr. Louis Bell and Mr. Chas. F. Scott, the latter being chief electrician of the Westinghouse Company. Mr. Clemens Herschel is also to read a paper on "Some Facts in Hydraulics," and Dr. Chas. E. Emery on "The Economic Use of Steam in Paper Making."

Conn. Elec. Lighting Association.

At the annual meeting of the Connecticut Electric Lighting Association officers were elected as follows: President, James English, of New Haven; treasurer, A. M. Young, of Waterbury;

secretary, Addison F. Hunie, of New Haven. After the meeting a dinner was given at Traeger's. Among those present were: James English, of New Haven; A. R. Shepardson, of Waterbury; A. M. Young, of Waterbury; G. G. Blakeslee, of Naugutuck; A. Grannis, of Bridgeport; C. H. Nettleton, of Derby; L. P. Gidding, of New Milford; F. E. Copperthwaite, of Danbury; Prof. C. G. Robbins, of Hartford; A. J. Purrington, of Stamford; M. Crawford, of Stamford; H. L. Mansfield, of Middletown; W. G. Bushnell, and Addison F. Hunie, of New Haven.

E. H. Archibald's Lecture before the Nova Scotian Institute of Science.

We are in receipt of a reprint from the transactions of the Nova Scotian Institute of Science, Vol. IX., Session 1897-98, entitled "On the Calculation of the Conductivity of Aqueous Solutions Containing Potassium and Sodium Sulphates," by E. H. Archibald, B. Sc., Dalhousie College, Halifax, N. S. The pamphlet contains a description of experiments and apparatus and tables on the concentration, dilution, and conductivity of various mixtures.

Remarkably Large Preliminary List of Exhibitors for the May Exhibition.

THE manager of the Electrical Exhibition, Mr. Marcus Nathan, has kindly furnished us with the accompanying preliminary list of exhibitors at the Madison Square Garden, for next May. We understand that between 20,000 and 30,000 square feet has thus already been preoccupied, and that as compared with the Electrical Exhibition two years ago, the applications are five times greater than at the corresponding period, in advance of the event.

REPORTS OF COMPANIES

Bell Telephone Output.

The American Bell Telephone Company made a net increase of 15,820 instruments in licensees' hands under rental for the first month of the fiscal year ended January 20, a record not often exceeded. Comparative figures of telephone movement follow:

January—	1898	1897	1896	1895
Gross output	25,861	14,437	17,620	7,631
Returned	10,041	6,401	7,568	5,945
Net output	15,820	8,036	10,052	1,686
Total outstanding Jan. 20..............	936,513	780,325	685,028	585,352

Kinloch Telephone Co. In St. Louis.

At a meeting of the stockholders of the Kinloch Telephone Company in their offices in the Century Building, St. Louis, recently, a resolution in favor of issuing $1,000,000 in bonds was adopted. There was only one vote cast, and that was by Breckinridge Jones, representing the Mississippi Valley Trust Company, in its capacity as trustee. The issuance of the bonds had been decided upon some time before, and the action was said to be purely formal, but necessary in order to carry out the provisions of the law. In speaking of the bonds, General Manager H. J. Hanford said they had all been subscribed for some time by the directors and stockholders of the company, but that they had not decided when the bonds would be issued, as they had not yet been printed or engraved. Continuing, he said: "The inside wiring into the homes and offices of 3,300 subscribers has been completed, and the work is proceeding at the rate of about 100 a day. We have also 500 telephone instruments up and ready for service, with the exception of a few parts, which might be subject to injury if put on the instruments when they are not in

actual service. We have received 800 more instruments and are having them put together."

ST. LOUIS, MO.—The Imperial Electric Light, Heat and Power Company has a permit for the erection of a two story generating house, at Tenth and St. Charles streets, to cost $40,000.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued February 1, 1898.

Alarms and Signals:—

ELECTRIC FIRE-ALARM CIRCUIT AND SIGNAL BOX. L. G. Rowand, Camden, N. J., 598,160. Filed January 5, 1897. Means to prevent, within certain limits, signals being sent from more than one box at the same time.

ELECTRIC CIRCUIT CONTROLLER. W. T. Budds, Charleston, S. C., 598,358. Filed August 30, 1897. Designed for call box systems, by the use of which a break in the main wires may be located.

FIRE AND BURGLAR ALARM SYSTEM. C. P. Bostian, Milton, Pa., 598,410. Filed April 27, 1897. Details of construction.

Conductors, Conduits and Insulators:—

INSULATING ATTACHMENT FOR ELECTRICAL CONNECTORS. R. P. and J. D. Osgood, Methuen, Mass., 598,109. Filed June 28, 1897. Comprises a rigid jacket of vulcanized fiber made to fit over and around the connnector and accommodate the binding screws.

ELECTRICAL CONDUCTOR. L. C. Werner, Broadbrook, Conn., 598,260. Filed June 15, 1897. Designed for use in connection with the line wires of a signal system in which it is necessary for a vehicle to make traveling contact with a conductor extending along the line.

TERMINAL HEAD FOR ELECTRICAL CONDUCTORS. C. H. Sewall, Chicago, and H. E. Precunier, Oak Park, Ill., 598,328. Filed August 22, 1896. Comprises a metallic case; conducting stems; non-conducting bushings surrounding the stems and extending from the inside to the outside of the case and metallic connectors mounted upon the bushings on the outside of the case.

Dynamos and Motors:

ALTERNATING CURRENT MOTOR. A. Heyland, Frankfort-on-the-Main, Germany, 598,092. Filed December 29, 1896. Method of producing phase difference between the two inducing circuits, consisting in causing one of the circuits to be powerfully affected by the reaction of the secondary member, while reducing the effect of the reaction upon the other circuit.

BRUSH HOLDER. A. J. Oehring, Chicago, Ill., 598,271. Filed June 30, 1896. Combines with the commutator brush, a dog bearing laterally upon it, and a spring actuating the dog to hold the brush securely in position.

Electro-Metallurgy:—

APPARATUS FOR ELECTROLYTICALLY PRODUCING ZINC. C. Hoepfner, Giessen, Germany, 598,180. Filed October 7, 1893. Comprises a vessel containing a zinc-chloride solution, an insoluble anode, and a discoidal revolvable cathode dipping partly into the solution, and means for preventing chlorine bubbles forming at the anode.

APPARATUS FOR ELECTRODEPOSITION OF GOLD AND SILVER. E. Andreoli, London, England, 598,193. Filed October 1, 1895. Employs anodes of peroxidized lead acting in the presence of and in combination with a cyanid or cyanid-compound solution.

ELECTRODEPOSITION OF LEAD. E. P. Clark, New York, 598,313. Filed June 8, 1897. Consists in first partially changing an acetate-of-lead solution into an acetate-of-zinc solution and then depositing lead electrolytically.

Lamps and Appurtenances:—

ELECTRIC LAMP FOR BICYCLES. P. A. Dowd, Boston, Mass., 598,198. Filed July 10 1897. The lamp is supplied with current from a generator driven by contact with the tire of the front wheel.

ADJUSTABLE SUPPORT FOR INCANDESCENT LAMPS. W. J. Going, Amsterdam, N. Y., 598,218. Filed May 26, 1897. A bracket having a hemispherical cavity, a ring swiveled on the outer edge of the bracket, a part extending between and journaled in diametrically opposite sides of the ring, and a rod threaded on one end and extending through the part and adapted to bear upon the wall of the cavity.

SUPPORT FOR INCANDESCENT LAMPS. W. J. Going, Amsterdam, N. Y., 598,219. Filed July 21, 1897. Similar to above.

SUPPORT FOR INCANDESCENT LAMPS. W. J. Going, Amsterdam, N. Y., 598,220. Filed July 21, 1897. Similar to above.

SUPPORT FOR INCANDESCENT LAMPS. W. J. Going, Amsterdam, N. Y., 598,221. Filed July 21, 1897. Similar to above.

Measurement:

ELECTRIC METER. C. D. Raab, Kaiserslautern, Germany, 598,208. Filed December 30, 1896. Motor wattmeter for alternating currents. Provided with one or more metallic rotary armatures acted upon by two sets of magnetic fields.

ELECTRIC METER. C. D. Raab, Kaiserslautern, Germany, 598,209. Filed June 24, 1897. A motor wattmeter for alternating currents having a rotary armature without current supply, and a coreless solenoid, in combination with two coreless shunt field coils of like polarity so arranged as to form a common magnetic field.

Miscellaneous:—

ELECTRIC CONTROL DEVICE FOR ELEVATORS. J. D. Ihlder, Yonkers, N. Y., 598,097. Filed April 18, 1896. Employs a control-motor, and an electro-magnetic clutch, the clutch being provided with teeth.

INSTRUMENT WINDING DEVICE. A. J. Oehring, Chicago, Ill., 598,272. Filed October 12, 1896. See description on page 164, Feb. 10.

INSTRUMENT WINDING DEVICE. A. J. Oehring, Chicago, Ill., 598,273. Filed November 28, 1896. Similar to above.

ELECTRIC HEATER. E. E. Cruzen, Baltimore, Md., 598,303. Filed August 7, 1897. An electric heater for drying canals in the roots of teeth.

AUTOMOBILE VEHICLE. W. A. Crowdus, Chicago, Ill., 598,314. Filed October 9, 1896. Embodies an automatic clutch for picking up the load after the motor is energized.

ELECTRIC GAS LIGHTING APPARATUS. C. Eickmann, Indianapolis, Ind., 598,316. Filed July 3, 1897. Consists mainly in a vessel in which ignition and explosion take place to ignite the gas escaping from the burner.

ELECTRIC FURNACE. J. E. Hewes, Philadelphia, Pa., 598,318. Filed April 27, 1897. Designed for the production of calcium carbide by the incandescent process.

ELECTRIC CIGAR LIGHTER. W. F. Kessler, Auburn, Ind., 598,489. Filed July 22, 1897. Details of construction.

Railways and Appliances:—

STATION INDICATOR. D. C. and J. M. Jones, St. John, Ky., 598,009. Filed March 26, 1897. Employs a magnet and an armature to primarily operate the escapement lever of a spring actuated mechanism.

CONDUCTOR FOR ELECTRIC RAILWAYS. G. Ritter, Stuttgart, Germany, 598,184. Filed October 16, 1896. Three-wire system of distribution for railways.

MECHANISM FOR STARTING, STOPPING AND CONTROLLING SPEED OF MOTORS OF ELECTRIC CARS. F. H. Foster, Brooklyn, N. Y., 598,199. Filed August 12, 1897. Means to control the entire number of cars from any platform.

Switches, Cut-Outs, Etc.:—

FUSIBLE CUT-OUT. E. A. Lowe, North Plainfield, N. J., 598,106. Filed March 5, 1897. The terminal wires are screw-threaded and held permanently within a box of insulating material and the fuse is held by spring clips connected to the terminal.

Telephones:—

TELEPHONE SYSTEM. C. A. Barron, R. T. Reid and J. L. McDonnell, Tacoma, Washington, 598,172. Filed April 5, 1897. "Party line" system.

TELEPHONE SYSTEM. R. T. Reid and J. L. McDonnell, Tacoma, Wash., 598,183. Filed May 7, 1897. Means to prevent a subscriber on a party line from "cutting in" while the line is in use.

POLARIZED SIGNAL BELL. F. R. McBerty, Downer's Grove, Ill., 598,269. Filed November 24, 1896. Signal bell for telephone substations. Details of construction.

SELF RESTORING ANNUNCIATOR. J. Steiner, Brooklyn, N. Y., 598,276. Filed May 23, 1896. Adapted for telephone boards. Details of construction.

TELEPHONE APPARATUS. F. B. Cook, Chicago, Ill., 598,285. Filed March 25, 1895. Means to obviate "noise" in unbalanced circuits.

PERSONAL

MR. R. R. BOWKER, first vice-president of the New York Edison Company, left for Europe last Saturday to obtain a much needed rest.

MR. L. A. FERGUSON, electrical engineer of the Chicago Edison Company, left for Europe on the "Teutonic" on Wednesday last, for a trip of four or five weeks.

MR. HERBERT LLOYD, general manager of the Electric Storage Battery Company, has been elected a director of the company. We congratulate Mr. Lloyd on this recognition of the faithful services rendered by him to the company.

THOS. A. EDISON is the subject of an interesting illustrated interview in that admirable new publication "Success." There are several views of Mr. Edison in his characteristic attitudes, and the article is full of good notes. Mr. Edison, by the way, was 51 last Friday, and looks hale enough to live midway into the next century. Mr. Edison has recently protested in the papers against the use of his name as author in connection with a fiction about attacking the planet Mars.

MR. HERBERT A. WAGNER, E. E., of the Wagner Elec. Mfg. Co., of St. Louis, Mo., was a welcome visitor to New York last week.

THE STOCK MARKET

Many Favorable Conditions.

There are various signs of improving business, but the most important have been the buoyancy of the iron and steel market, and the higher price for cotton; indeed, the general level of prices has continued excellent. As for the railways, they are doing splendidly, and January was the best month, excepting only November, since the panic of 1893. Out of 112 systems, no fewer than 102 report gains. Bank clearings for last week show a gain of 52 per cent. over the same week in 1897, and actually 82 per cent. more than the corresponding week in 1894.

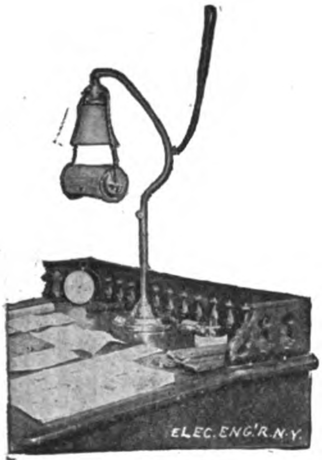
Business failures for the week were 278 as compared with 381 for the week in 1896.

What electricity can do for local traction is shown in the phenomenal advance of New York Metropolitan since its extensive adoption of the conduit system. Even within the past week on sales of 91,000 shares it has gone from 149 to 169. The sales of Western Union were 16,606 shares around 92. Of General Electric, 39,793 shares were sold around 38 and 39. It is rumored that the coming annual report will show 5 per cent. earned on the common stock. New York Edison is firm on small sales at 134, and Brooklyn Edison is rising steadily, being now 112. In Boston, Bell Telephone is up to 270.

Copper, New York, is 11 cents. Heavy steel rails, Eastern mill, are $18 per ton.

TRADE NOTES & NOVELTIES

The "Eureka" Desk Lamp.



A VERY unique and useful desk lamp for business men, banks, students, and the home has been patented by Mr. W. H. Sheppard and is called the "Eureka desk lamp." It is unsurpassed for convenience of operation and is a perfect safeguard for the eyes, being especially helpful to those who are compelled to do a great deal of reading and writing by artificial light. As will be seen from the figure, the apparatus consists of a bracket supporting an ordinary drop light and a cylindrical, carefully shaded desk lamp. By means of a switch in the socket of the lamp, four combinations are possible. By giving the key a quarter turn the lamp in the cylinder is switched in, as used for reading or writing purposes. In case visitors call, by another quarter turn of the key in the same direction, the upper lamp lights up the office. Should it be desired to conceal the writing or papers on the desk from the visitor, another quarter turn of the switch will extinguish the lamp in the cylinder, and the cylinder itself acts as a shade between the upper light and the desk. In case more light is desired on the desk, the cylindrical shade can be swung back and both lamps can be used for desk illumination. The lamp can be raised or lowered to suit the convenience of the person using it. It can also be attached to a combination or plain wall bracket or be attached to brass tubing fastened to the ceiling. For banks and offices where much writing is done, these ingenious devices are invaluable, as every business man will affirm that his eyesight is worth more to him than the price of a perfect desk lamp. The patent is for sale outright or on royalty by Mr. W. H. Sheppard, 235 West 125th street, New York.

New Trolley Cars For the New York Metropolitan Co.

The Metropolitan Street Railway Company has taken steps to provide new cars. President Vreeland a few days ago signed a contract with the Brill Company, of Philadelphia, for the purchase of 500 cars of the most improved construction. The cost of the cars will be nearly $900,000. Most of them are to be delivered early in April and the others as soon thereafter as practicable.

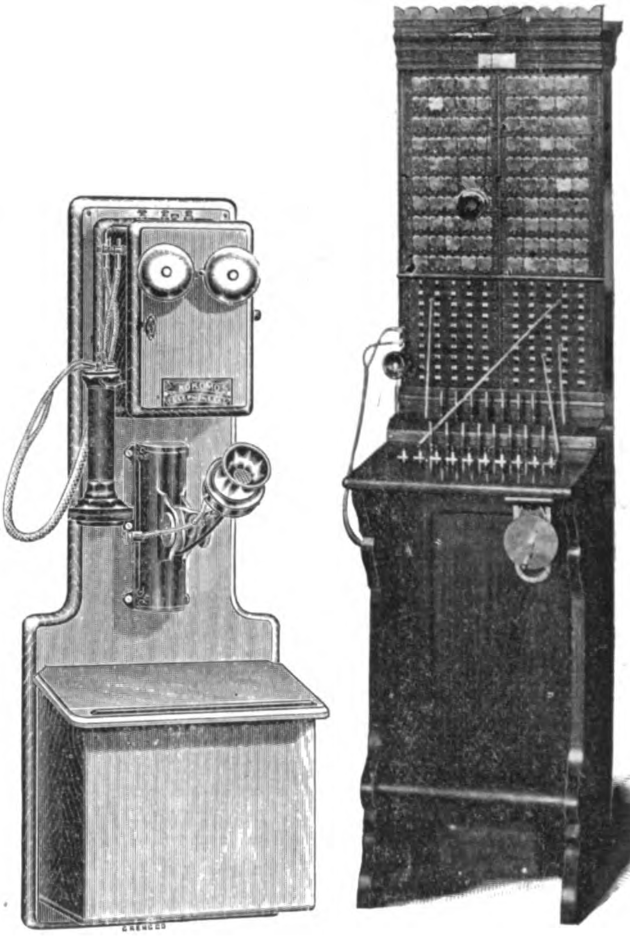
"Just as soon as we know that winter is behind us," said President Vreeland last week, "we shall go ahead and complete the work of construction on all our conduit lines."

The lines referred to are those in First avenue, Second avenue, Sixth avenue, Amsterdam avenue, Eighth avenue, Tenth avenue, Twenty-third street, and several other cross streets. Much of the work on some of these lines has already been done. That in Eighth avenue has so far advanced that it is hoped to run electric cars from the Astor House to the end of the line by the 1st of May.

The Metropolitan Company, since an agreement with the Third Avenue Company has been effected, does not look for any further opposition to the laying of conduits in Park Row from Centre street to Broadway.

The Kokomo Telephone Apparatus.

THE Kokomo Telephone and Electric Manufacturing Company, of Kokomo, Ind., are reporting an increased business in their high grade telephone apparatus and have just installed several large outfits in telephone exchanges. Their microphone transmitter is guaranteed against packing and has stood the most severe tests. Their exchange telephones will stand hard service, have a neat appearance and are built for use on long and short



KOKOMO TELEPHONE APPARATUS.

lines; one of these sets is shown in the figure. The new switchboard which this enterprising company has just placed on the market seems to fill the requirements of a substantial and practical board. The cut shows a 100 number board, which is 5 feet 6 inches high and 12 inches wide. The Mayer drop is used in the construction of this board, this being claimed to be the smallest and most perfect drop in the market. A very commendable feature of the operation of this board is the fact that the operator in ringing up a subscriber does not ring back in the ear of the subscriber who has called up the exchange. The number of operations has been decreased from five to four to connect two subscribers. It is claimed that the Kokomo switchboard has less cross talk than any other telephone switchboard on the market.

Besides the above, the company manufacture lightning arresters, cross connecting boards, receivers, induction coils, bells, batteries, magnetos, etc., and are in a position to fit out an entire exchange with their own standard apparatus. The company have received many flattering testimonials from persons using their apparatus and every exchange they have furnished and every telephone they have sold stands as a reference of the superior merits of their goods.

The Keystone Arc Light Voltmeter and Ground Detector.

THE Keystone arc light voltmeter and ground detector, manufactured by the Keystone Electrical Instrument Co., Philadelphia, Pa., combines in one instrument: A voltmeter which will indicate the actual voltage of each circuit, or the total voltage of the generator, and consequently the number of lamps burning, and a ground detector which will indicate a ground, determine its character and location. It will indicate the character of the ground, its resistance, and its location on the lines by taking three readings and equating them in simple formulæ. It can be used when the circuit is "alive" thus giving results under working conditions. It replaces a cable testing set which has proved extremely unsatisfactory owing to the many microphone contacts in circuit. It is self-contained, well made, accurate, reliable, dead-beat, unaffected by external fields or changes in temperature, easy and safe to manipulate, and low in price. In connection with a set of switches and a battery of cells, or an ordinary incandescent circuit, it can be used to test the continuity of the line and the resistance from line to earth,

KEYSTONE ARC LIGHT VOLTMETER AND GROUND DETECTOR.

during the day, and for this purpose will be found much easier to handle, more accurate in results and quicker in action than any galvanometer and bridge method.

An idea of the general appearance of the instrument may be obtained from the cut, and, in further explanation, we would say that it consists of a compound galvanometer system, mounted in a case which effectually shields the instrument from the influence of external fields. This case is finished in oxidized copper, well lacquered, and presents an attractive appearance. The scale is practically uniform from zero to maximum reading, indications are dead-beat, and the temperature co-efficient of the wire employed is so small that external changes of temperature make no difference in indications.

Packard Transformer, Model 1898.

The New York and Ohio Company, of Warren, Ohio, well known as makers of the Packard lamps and transformers, have for some time past been developing a new series of transformers which are now ready for the market. These will be known as the Packard Model '98. The New York and Ohio Company claim that these transformers are fully equal and in some respects superior to any in commercial use. Particular claims are made regarding regulation, a point in transformer design which in the endeavor to obtain an exceedingly low core loss, has been too often considered of secondary importance. The New York and Ohio Company have secured the services of Mr. H. W. Wiswell, who for several years has been connected with the transformer department of the General Electric Company. Mr. Wiswell's experience in this particular branch fits him admirably for his new duties. The New York office has been established at No. 1 Broadway under the personal supervision of Mr. J. W. Peale, president of the company, who, assisted by an efficient force, will handle the Eastern business.

Large Orders For Walker Apparatus.

The Standard Light and Power Company, of Dallas, Texas, has placed an order with the Walker Company for two alternators, one of 225 and the other of 325 k. w. capacity. They are to be direct connected to "Erie" engines and are designed to run at 125 revolutions per minute. The current will be two-phase and 60 cycles. In addition to these the Walker Company will furnish them with two direct connected railway generators of 225 and 325 k. w. capacity, respectively.

Two alternating generators of 250 k. w. capacity each are being built for the North River Electric Light and Power Company, of New York City. They are to be of the belted type.

Townsend, Reed & Company, of St. Louis, have purchased for the St. Louis, Belleville and Suburban Electric Railway two 200 k. w. direct connected Walker railway generators, besides eight double 10-S railway equipments with "S" controllers.

On the other side of the Atlantic the Glasgow Municipal Tramway will place a number of Walker motors on its cars at an early date, while the Electric Railway, of Alexandria, Egypt, will increase its present Walker plant by the addition of one 150 k. w. belted generator with switchboard, and four double 3-N equipments.

Weston Electric Appliance Co.

The announcement is made of the formation of the Weston Electric Appliance Company, with a capital stock of $750,000. The incorporators are Edward Weston, of Newark, N. J.; F. O. Matthiesen, of New York, and H. E. Neise, of Jersey City. It is stated that the concern will build a large new factory on ground already purchased near Waverley, N. J.

"Gold Standard" Electric Heaters for the South Side Elevated Railroad, Chicago.

The equipment of the South Side Elevated Railroad, of Chicago, with electric power is rapidly nearing completion. The Sprague Electric Company's system of propulsion of cars and trains on this road has already proven its merit and given general satisfaction. During the past winter the railroad officials sought to determine the advisability of equipping their cars with electric heaters, and in order to satisfy themselves that the adoption of electric heaters would be to their advantage and at the same time find out which heater of the many offered was the most suitable for the purpose, the South Side Road had some very careful and extensive tests made of the heaters of five of the most prominent electric heating companies in this country.

Each of these companies was given the privilege of equipping a car and the five cars thus equipped were run during the past winter. The result was that the contract was awarded to the Gold Car Heating Company, of New York and Chicago. The car which the Gold Company equipped was supplied with twenty-four of the improved "Gold Standard" electric heaters. The heaters were wired to permit of six graduations of temperature, which was controlled with a regulating switch. The car was comfortably heated in the coldest weather and the regulation of the temperature to suit the outside conditions was entirely satisfactory. With the "Gold Standard" electric heaters a perfect uniformity of the temperature was maintained at all times in all parts of the car.

This contract covers the entire equipment of the South Side Elevated Railroad and calls for about three thousand electric heaters. This is one of the largest orders ever placed for electric heaters and the Gold Car Heating Company have reason to feel proud of their success.

Carbons For Enclosed Arc Lamps.

Cored carbons and solid carbons for enclosed arc lamps, manufactured by the Washington Carbon Company, of Pittsburg, Pa., are now attracting a great deal of attention. Their goods are held to be equal to any on the market; the consequence is this company's business is considerably on the increase and consumers are supplied in any quantity, even though it may be necessary "to break packages." This company caters to small and large trade and is prepared to ship on a moment's notice.

A New Plant for the Boston Electric Light Co.

The Boston Electric Light Company has concluded a contract with the General Electric Company for the equipment of its great generating station now in course of erection. Up to the present the Boston Electric Light Company has operated a number of stations throughout Boston. Two of these, however, have recently been abandoned to make way for the new railroad stations now being built and the company has, therefore, decided to consolidate all the small stations into one mammoth generating plant to be erected in South Boston.

The system will involve the use of the three-phase alternating current, selected on account of its greater flexibility and the fact that by its use the value of the present distributing system will not be diminished. The dynamos will be four in number each of 1,500 k. w. with a reserve capacity of 50 per cent., giving a total output of 12,000 h. p. They will be of the revolving field type, to permit a high voltage to be taken directly from the dynamo to the wires without the use of transformers to increase the pressure. The revolving field on each dynamo will be mounted on the shaft of an engine, and the voltages of the generated current will be 2,200 volts. To excite these dynamos, two smaller ones each of 100 h. p. will each be driven by a synchronous motor. In addition, eighteen large synchronous motors each of 200 h. p. will drive thirty-six arc lighting machines. Each motor will be set between two Brush 125 light arc dynamos, the shaft of the motor armature being extended to become the shaft of the armature of the arc dynamos. The power transmission for this arc lighting plant, therefore, will be confined to the width of the dynamo room. If this system were not employed small engines would have to be used, whereas by the method selected only the large main engines will be employed.

For the power circuits, that is for the stationary motors, two rotary converters each of 500 k. w. or 650 h. p. are included in the contract. These will take the three-phase alternating current and convert it into direct current at about 550 volts. For the incandescent lighting system, the three-phase current wires will simply be connected to the existing net work, using the transformers now in use.

Large Orders for Chloride Accumulators.

The very extensive application of chloride accumulators, manufactured by the Electric Storage Battery Company, of Philadelphia, is indicated by the large business being done by the company. The latest contracts cover batteries to be used in connection with electric elevators in the 30-story office building being erected on Park Row, New York, where 58 chloride accumulators of 3,500 ampere hour capacity will be installed; for the Cushman Building, New York, 118 320 ampere hour cells; the Dun Building, New York, 114 1,100 ampere hour cells. The State Mutual Life Assurance Building, Worcester, Mass., have contracted for an increase in their original plant. Very large plants are being constructed for the Chicago Edison Co. and the Buffalo Railway Co. Chloride accumulators are being installed in the residences of Mr. Jno. I. Waterbury, Morristown, N. J., and Mr. G. P. Morosini, Riverdale, New York. Also in Mr. Howard Gould's new steam yacht, Niagara, and Mr. Lloyd Phoenix's yacht, Intrepid. The American Fire Insurance Co.'s building in Philadelphia is being equipped with a battery for night lighting. The Germantown, Pa., Hospital, which has operated a battery of chloride accumulators for about two years, is increasing the capacity of its plant by 50 per cent.; 108 cells, ranging in capacity from 400 ampere hours to 1,200 ampere hours, have been furnished to the Cleveland Telephone Co., and the Southern Bell Telephone Co.; 1,300 cells have been supplied for fire alarm work at Portland, Oregon; Augusta, Ga., and St. Paul, Minn. For telegraph work the Lehigh Valley Railroad Co. has ordered 208 cells; the Southern Pipe Line Co., 50 cells; the Great Northwestern Telegraph Co., 265 cells; the C. M. & St. P. Ry. Co., 276 cells, and the Postal Telegraph & Cable Co., 220 cells. The General Electric Co. have contracted for 112 cells of from 160 to 200 ampere hours' capacity; the Patton Motor Co. and the National Electric Car Lighting Co. are installing 432 cells in conection with their systems, and the State School of Mines, Colorado, has equipped its laboratory with 52 cells of 160 ampere hours capacity.

CHICAGO proposes to cut down a lot of overhead wires if they are not removed by March 1.

United States Electric Plants For Malaga, Spain.

United States Consul Bartleman, of Malaga, Spain, transmits a newspaper extract which states that two companies have sprung into existence there to supply the demand for electric lighting. With a population of about 125,000, inhabiting some 20,000 to 25,000 houses or flats, adds the article, it is evident that there is ample room for two works. The great demand for electricity, however, has rendered essential the erection of further generating plant, and, as the engineering strike in England has prevented the completion of English-made machines, the directors have had to place their orders in other quarters. They have arranged with the Westinghouse Electric Company, of Pittsburg, to supply immediately two sets of plants, each of 135 k. w. capacity, and these are now on the way to Malaga and will be erected early in the new year. The total capacity will thus be raised to 765 k. w., and, in addition to this, we understand that the directors have under consideration the consulting engineer's estimates for two further sets of plant, each of which is to be of 300 k. w. capacity. After the works had been in operation for less than two months, upwards of 800 consumers had applied for a supply of electricity, and that 7,200 lamps were then connected to the mains. On the day when the supply was started, the maximum load was 16 k. w., and the output for the day only 29 units, but by November 30, the load had reached 128 k. w., and the output for the day had advanced to 884 units, while on December 11, 148 k. w. was recorded as the highest load and 1,093 units as the day's output.

Siemens & Halske Work in New England.

The Siemens & Halske Electric Company of America have just obtained, through Mr. H. C. Spaulding, their New England representative, the contract for the new municipal lighting plant at South Norwalk, Conn. This plant will be of special interest as it will be run on a straight 220 volt two-wire system for arc and incandescent lights as well as power. While a number of these stations have been put in abroad, there have been comparatively few installations of the kind here, except for isolated plants.

The New England business of the Siemens & Halske Company has been very largely increased during the past year, one of the most notable contracts being one for the Boston City Hospital plant, which is considered one of the finest of the kind in the country. Another plant is being installed in the new theatre at Springfield, Mass., in which lights for the entire edifice as well as some adjoining buildings will be furnished from two 75 k. w. machines running at 100 r. p. m. Among other large installations lately completed may be mentioned the plant in the Academy of Music, Fall River, Mass., and one in a large manufacturing concern, where current is furnished by two machines of 400 k. w. capacity. The generators in all the above mentioned plants are of the standard Siemens & Halske external armature type, while a large number of internal armature belted machines in both the slow and moderate speed types for lighting and power service have been installed in Boston and vicinity during the past few months.

A Big G. E. Railway Generator For Louisville, Ky.

The largest generator for electric traction work ever built is now under construction at the works of the General Electric Company at Schenectady, N. Y. When finished it will be installed at the Logan street station of the Louisville Railway Company, Louisville, Ky. On account of its large diameter the armature of this generator cannot be transported over the railroads in its completed state, either erect or on its side. The generator will, therefore, be assembled in Louisville. The completed machine will have 22 poles, an output of 2,400 kilowatts or 3,000 horse-power, and will be driven at a speed of 75 revolutions per minute by a 4,000 horse-power, cross-compound engine to be furnished by the Allis Company.

The generator will be constructed to stand an overload of about one-third, so that the capacity in case of emergencies may equal 3,200 kilowatts or over 4,000 horse-power. The principal dimensions of the machine will be as follows: Diameter of field frame, 19 ft. 0 in.; width of field frame, 4 ft. 1 in.; diameter of armature, 12 ft. 9 in.; diameter of commutator, 9 ft. 3 in.; diameter of shaft, 2 ft. 3 in.; total weight of armature and commutator, 83,000 pounds; width of armature, 5 ft. 0 in.; width of commutator, 21 in.; total width of generator, 77 in.

The total weight of generator complete is 174,000 pounds.

Previous to the manufacture of this machine the largest generators constructed for electric railway work were those of 1,600 kilowatts or about 2,500 horse-power, the first of which was used in the Intramural Power House at the World's Fair.

Dynamos of the same enormous output have since been installed in Philadelphia, Boston and Chicago. Four are also operating in the Kent avenue power station of the Brooklyn City Railroad.

CATALOGUES.

THE BROWN & SHARPE MANUFACTURING COMPANY, of Providence, R. I., have just issued a new edition of their general catalogue of machinery and tools. The catalogue has been thoroughly revised and contains 437 pages—20 more than the preceding one. The large number of tables it contains make it especially valuable to the workman as a book of reference. These catalogues are mailed, on application, to any address without charge, or are furnished by the hardware and supply dealers.

HARVEY HUBBELL, 33-35 Organ street, Bridgeport, Conn., manufacturer of machinery, tools and brass machine screws, has issued a very handsome catalogue illustrating the various types of apparatus he manufactures. The typography of the catalogue is highly commendable, and the general arrangement and the description of his machinery certainly do justice to the high grade work turned out by the establishment.

THORPE, PLATT & COMPANY, 97-103 Cedar street, New York, are sending out catalogues descriptive of their standard high pressure fittings and flanges. The book contains a description of special fittings and gives tables showing the sizes of flanges for 750 and 1,500 pounds pressure per square inch. The second part of the book contains information for use in designing hydraulic plants, which is of considerable value to those who have to design and use hydraulic machinery. The information on riveting, forging and flanging has been worked up from experiments made in the shops. The formula for flanging dies, by T. R. Browne, will be found of considerable value to all manufacturers using flanging presses. The book contains a very complete index.

THE STOW MANUFACTURING COMPANY, Binghamton, N. Y., have issued a very handsome and complete catalogue illustrating the numerous uses to which the Stow flexible shafts have been put. Among these may be mentioned wood carving, cloth cutting, metal polishing, sand papering, stone drilling and polishing, boring, flue cleaning, multiple and mining drills, dental engines, surgical instruments, die work, and many others. The catalogue calls attention to their ironclad electric motor, which is practically dust and water-proof. All their machinery is made on the interchangeable system and the flexible shaft can be used in connection with any tool.

GENERAL ELECTRIC COMPANY, in view of the large number of applications made for information, which is embodied in the second part of its recently issued Edison incandescent lamp catalogue, have published this information in a separate 16 page pamphlet of small octavo form. This information is of value to all users of incandescent lamps and the General Electric Company will be pleased to supply copies of the pamphlet.

ELMER P. MORRIS, manufacturers' agent for electrical material and other specialties, 15 Cortlandt street, has issued a very handsome and useful catalogue giving details of all the goods handled by him. It runs a length of over 100 pages, well illustrated, prices, etc.

PIERCE & MILLER ENGINEERING COMPANY.—In the article describing the new work of the Brooklyn Edison Company, in our issue of January 6, we omitted to mention that the large 3,000 h. p. triple expansion McIntosh-Seymour engine was contracted for by the Pierce & Miller Engineering Company, of New York. The engine is now undergoing a test.

NEW YORK NOTES.

THE FERRACUTE MACHINE COMPANY, of Bridgeton, N. J., manufacture a full line of sheet metal machinery, and during the last two years they have paid a good deal of attention to special presses for electrical work. They have recently supplied two of their large double-crank presses to the General Electric Company, of Schenectady, and four of the same style of presses to the Westinghouse Company, of Pittsburg. These have proved very desirable for cutting out large armature discs. They are heavy and built in the most careful manner, and with a number of improvements in the adjustments and arrangements of long strokes, etc., which are highly appreciated by the superintendents of the factories named. They are also building some new forms of machines for notching armature discs. They have recently issued a large circular illustrating their various presses, which they are mailing to all parts of the world.

EUGENE MUNSELL & COMPANY, of New York and Chicago, importers and dealers in amber "Mica" report a very gratifying demand for all their insulating specialties. The India "Mica" is being used very largely by electrical manufacturers and street railway companies both in this country and in Europe, on account of its being free from iron as well as its high insulating qualities.

THE OTTO ELECTRIC CO., 148 Times Building, New York, inform us that they have secured the rights and sole agency for the U. S. and Canada of the Cox thermo-electric generators. Their intentions are to manufacture the generators in this country and push the sale vigorously.

S. R. JONAP & COMPANY, Eighth avenue and Twenty-fourth street, New York City, have just installed a large number of standard Bergmann enclosed arc lamps, made by the General Incandescent Arc Light Company. They report having tried another make for some time, but have now changed over, as noted.

A. WIRSCHING & SONS, manufacturing electricians, have removed their office and factory to 61 and 63 Duane street, corner of Elm, New York City, where they will be glad to hear from old and new patrons.

THE EDISON MANUFACTURING COMPANY, 23rd street, New York, report that their business in Edison LaLande batteries has very largely increased during the last year, especially among railroads, which use these batteries for signal work and also among gas engine manufacturers, who use these batteries very largely for igniting purposes. They are bringing out a range of batteries with steel cells, which are so constructed that they will be absolutely liquid tight. These batteries are chiefly suitable for gasoline, launch and traction work and also for motor carriages. They also report considerable increase in business in electro-medical apparatus, including X-ray equipments, cautery transformers for the direct and alternating current and electrical centrifuges to run on the 110 volt direct, alternating and battery current.

THE ROBB CONDUIT AND UNDERGROUND ELECTRIC SYSTEM COMPANY, of New York City, has been formed; capital stock, $25,000. Directors: F. D. Robb and Dr. G. E. Crittendon, Hot Springs, Ark.; Fritz Andraea and Gertrude Hanbury, New York City; A. L. Wear, Cornwall.

NEW ENGLAND NOTES

THE BOSTON GAS LIGHT COMPANY are erecting a new gas plant at Commercial Point, in the vicinity of Boston. This new plant consists of a building about 52 feet wide and 185 feet long, having brick side walls and brick partition walls dividing the building into three distinct parts, made up of a generator house, blower room, and condenser room. No wood is used in the construction of the building, and it is absolutely fireproof. The floors are of steel throughout. The roof is covered with slate supported on steel roof trusses and framing. The contract for furnishing and erecting the steel roof work complete has been let to the Berlin Iron Bridge Company, of East Berlin, Conn.

WESTERN NOTES

WESTERN ELECTRIC COMPANY has placed in stock a large supply of Victor split insulators. This insulator makes a very effectual break insulator for overhead line wires and for guy wires.

THE HOPPES MANUFACTURING COMPANY, Springfield, O., manufacturers of live steam feed water purifiers and exhaust steam feed water heaters, report several large orders recently received through their Philadelphia office from the following concerns: The New York Sugar Refining Company, Long Island City, N. Y., three special live steam feed water purifiers aggregating 3,750 h. p. Also from the same company, three exhaust steam feed water heaters of 4,500 h. p. capacity. The Union Traction Company, Philadelphia, Pa., 3,000 h. p. live steam feed water purifiers, special for high pressure. The Springfield office also report sales to the Deering Harvester Company, Chicago, Ill., for 2,500 h. p. live steam feed water purifiers; a repeat order from the Proctor & Gamble Company, Ivorydale, O., for a 1,000 h. p. purifier; Louis Sands, Manistee, Mich., 1,000 h. p. purifier; and Thomas & Smith for Chicago Public Library, four special live steam feed water purifiers of 300 h. p. each.

THE NEW EXTRA B. B. IRON BOX BELL, introduced and handled by the Central Electric Company, of Chicago, has proven to be one of the best sellers ever introduced into that branch of the electrical business. Its many new electrical and mechanical features commend it to cautious purchasers.

ADVERTISERS' HINTS

THE ELECTRICAL MANUFACTURING COMPANY, 329 Fourth avenue, New York, are carrying a full line of electrical novelties and miniature incandescent lamps.

T. J. COPE, 3244 North Fifteenth street, Philadelphia, advertises a device for threading conduits, which he claims to be the only machine of the kind manufactured. It has a record of many million feet of conduit.

THE KOKOMO TELEPHONE AND ELECTRIC MANUFACTURING COMPANY, Kokomo, Ind., advertise the new "Kokomo" transmitter designed for exchange and long distance service.

THE DELAWARE HARD FIBRE COMPANY, Union and Tenth streets, Wilmington, Del., advertise fibre for insulation, and will send their catalogue and samples on request.

THE ELECTRIC RAILWAY EQUIPMENT COMPANY, Cincinnati, Ohio, advertise mast arms with automatic cut-outs for wooden or iron poles.

THE VULCANIZED FIBRE COMPANY, Wilmington, Del., supply "vulcanized fibre" in sheets, tubes, rods and special shapes for insulating and mechanical purposes.

THE CROUSE-HINDS ELECTRIC COMPANY, Syracuse, N. Y., illustrate their patent tubular arm switch. Their descriptive catalogue of switches, switchboards, panel boards and electrical specialties may be obtained.

I. P. FRINK, 551 Pearl street, New York, submits a list of architects for whom he has installed important work.

G. M. ANGIER & COMPANY, 64 Federal street, Boston, Mass., set forth the merits of the "Paragon" series enclosed arc lamp.

CHAS. E. GREGORY COMPANY, South Clinton street, Chicago, Ill., publish an up-to-date list of bargains in dynamos, motors, arc lamps and transformers, which they have in stock ready for shipment.

THE HART & HEGEMAN MANUFACTURING COMPANY, Hartford, Conn., call attention to one of their many styles of switches whose various points of excellence have made them so popular.

WEST POINT, MISS.—The plans and specifications for the city electric light plant are now in the hands of the printer. The contract will be let March 8, 1898. Parties wishing for copies of the documents should address the mayor. The city has on file also plans and specifications for a reservoir to be added to their water work plant.

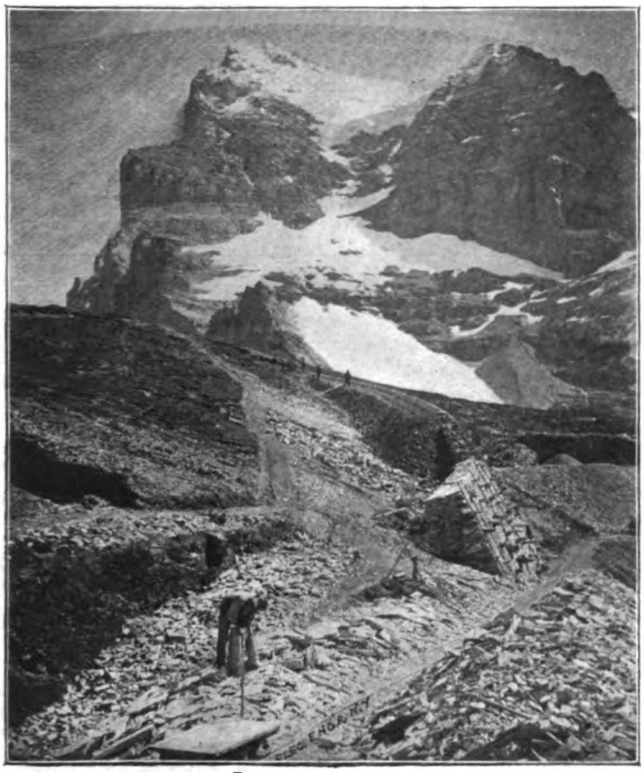
ELECTRIC TRANSPORTATION

"The Trolley to Heaven"—The Jungfrau Railway.

BY L. BAYLY, E. E.

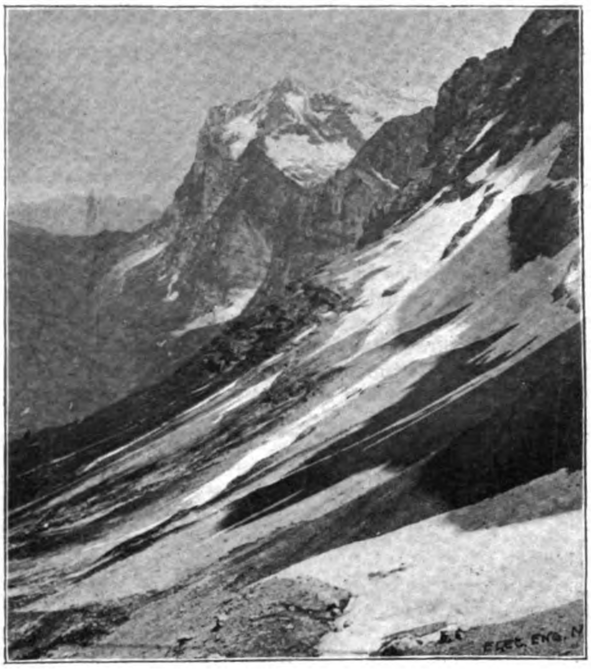
MOST people are aware of the enormous popularity of the recently-introduced cogwheel railways in Switzerland. To a host of its minor conquests Herr Guyer-Zeller's undertaking comes as a worthy and closing triumph to this great century of engineering. For the benefit of those who are not familiar with the main facts about the route adopted, I will condense geographical information as much as possible.[1] After leaving the station at the Little Scheidegg the line winds along at a gentle slope up the Eiger glacier, then, pausing for a moment at the edge of a 6,000-foot precipice—Grindelwald-blick—disappears bodily under the ice, and reappears, after passing beneath the glacier, 3,000 feet higher up, at Mönch. Hence a new tunnel takes us to within a hundred feet of the Jungfrau's summit, where an electrically-worked lift completes our journey.



JUNGFRAU ROAD, FIRST STATION—"EIGERGLETSCHER."

As might be supposed, the gradients on this line vary considerably. The maximum incline between the stations Eigergletscher and Kallifirn—is about 25 per cent., or one mile in every four. The other sections average from 12½ per cent. to 23 per cent. In the construction of the line, horizontal stretches have been avoided as much as possible, a regular strain being deemed more healthy for the machinery than an intermittent one.

The disposition of the rails is the same as on the other Swiss railways. A series of cogwheels, set in movement by electric motors, gear into a cogged rail of peculiar construction. It is of rolled steel, and capable of supporting the weight of the train (about 35,000 kilos) on a gradient of 30 per cent. It comes from the shops of the Bochumer Verein, Zurich. According to geological researches, nearly three-quarters of the rock through which Herr Guyer-Zeller's railway will have to pass on its way to the summit of the Jungfrau—13,000 feet above the sea-level—consists of a brittle, half-crystalline jurassic formation (malm), as remarkable for its resisting powers to weather as for the ease with which it can be loosened by explosives. The remainder of the route will necessitate tunnelling through gneiss. The unvarying temperature of the tunnels—always below zero—renders accidents from a sudden thawing of the ice extremely improbable, and interior brickwork can be dispensed with throughout the greater part of the line.



SECOND STATION—"GRINDELWALDBLICK."

Here there steps in an interesting question concerning the possibility of the geological strata shifting with regard to each other, and thus altering the level of the line in places. To obviate this, the tunnels are to be lined with masonry wherever the strata changes, Portland cement, capable of being applied at a temperature of ten degrees below zero, being used throughout.

UNDER THE EIGER PRECIPICE.

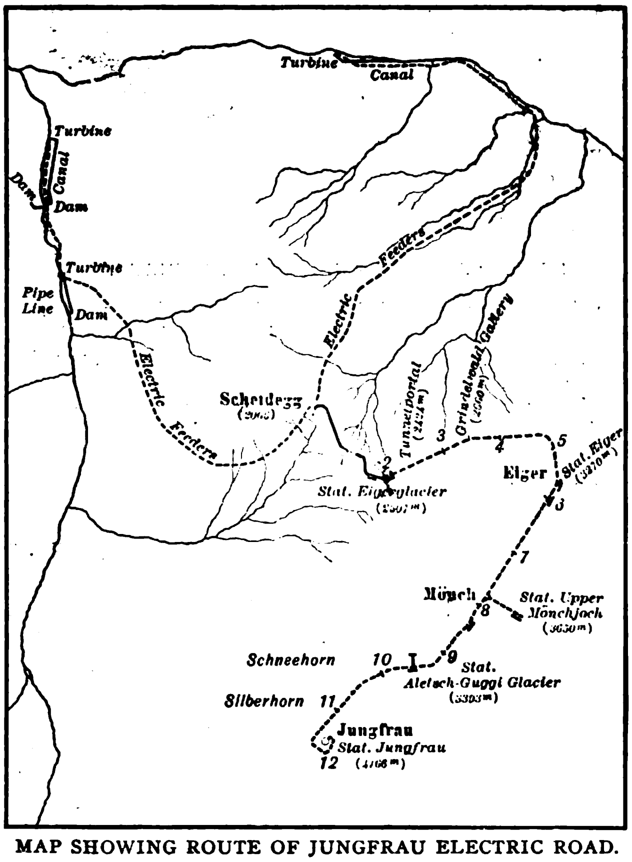
The total cost of masonry is estimated at 250 francs per metre.

[1]Preliminary illustrated articles on this road have appeared in The Electrical Engineer, Vol. XXII., No. 446, Nov. 18, 1896, and Vol. XXIV., No. 490, Sept. 23, 1897.

PERSPECTIVE VIEW, ROUTE OF JUNGFRAU ELECTRIC ROAD.

As already 750,000 francs have been voted for this feature alone. 3,000 metres of the tunnel will be encased, for safety's sake, in masonry.

At first it was feared that difficulties from water might prove perplexing. Starting from the Little Scheidegg, the line climbs gently up the grassy slope of the Eiger and enters boldly under the body of the glacier, not to emerge until it reaches the Jungfrau-Joch, 4,000 feet higher up, from whence it again dives into the snow to complete its journey. Thus it will be seen that the line is practically covered with ice the whole way, and to judge from the boiling torrents that rush from the hearts of these icy giants, it would at first seem very probable that the trip to the Jungfrau summit would be a damp one at best.



MAP SHOWING ROUTE OF JUNGFRAU ELECTRIC ROAD.

Here, however, comes energetic consolation. The temperature throughout the whole length of the tunnels is below zero, and water, save in the form of ice, cannot exist—unless, as Herr Guyer-Zeller ironically remarks, they should happen to strike a boiling spring, in which case pipes will be laid to conduct the water to the nearest station, where it would certainly prove useful.

The tunnels themselves, with a maximum diameter of 14 feet, will be helped along by electric drills, actuated by motive power from the Lauterbrunnen Valley. Experimental tests in stone torn from the precipices of the Eiger and Jungfrau, have already taken place, and have proved entirely satisfactory. The electric drill is as yet in its youth, but Herr Guyer-Zeller's railway seems likely to give it a chance of coming forward.

The attacks on the Eiger slope, commenced a month ago, have served to bring the new explosive, "lithotrit," into growing reputation. It is a compound invented by Herr Alfred Demeuse, of Zurich, and contrasted with the more venerable dynamite, it possesses manifest advantages in price, in the fact that neither heat or cold can touch it, in that neither hammering nor igniting can cause it to explode, and last, but not least, in the fact that its working generates no noxious gases—an important consideration for men who have to tunnel beneath five miles of glacier.

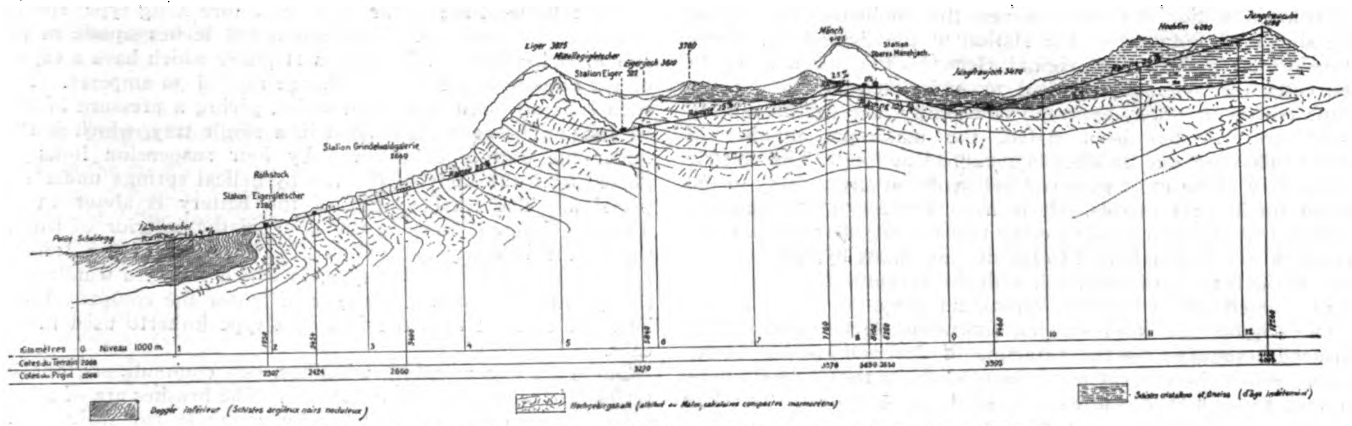
Another curious fact about this new explosive is that it

VIEW LOOKING BACKWARD FROM FIRST STATION.
(The slope of the Jungfrau is on the left.)

possesses the power of burning brilliantly under water. In a seance held by Herr Demeuse, at his workshops previous to the signing of the contract with the Jungfrau Railway authorities, the writer was a witness to this curious fact. The use of lithotrit is also far less dangerous than dynamite, as the nature of the explosion, though sufficient to shatter the resisting structure of rock, does not give rise to that intolerable rain of debris that forms one of the leading dangers attendant on the use of the older explosives.

As mentioned before, the low temperature prevailing in the tunnels renders it necessary to bring all the water used for washing the drills up on trucks in the form of ice, to be thawed by fire or electricity. Instead of being allowed to flow away, thus congealing on the walls or floors of the tunnel, it is freed from its impurities by a system of siphons and used over and over again.

About 350 francs per metre is estimated as the cost of the tunnels, the first five miles being undertaken by a firm of Rhenish engineers, who guarantee an advance of at least four metres a day. It is perhaps generally known that the Peruvian Central Railway reaches in places a height of 4,470 metres



PROFILE AND GEOLOGICAL SECTION, JUNGFRAU ELECTRIC RAILWAY.

above the sea level, without being protected by tunnels. The Jungfrau line, at its highest point, only attains 4,166 metres.

The question of weight in the trains that run to the summit has been settled as follows: One carriage, with seats for 30 people, 15,000 kilos; one baggage wagon, 5,400 kilos; 80 passengers, 5,600 kilos, or a total of 26,000 kilos.

This renders a delivery of

$$26\,(250 + 10)\,8.5 = 212 \text{ HP}$$

necessary at the crank-shaft, or in the case of electricity, at the motor axle.

Each locomotive contains two motors of 125 h. p. apiece, working directly into the cogwheel gearing. The rails are of cast steel, and a brake of peculiar construction, actuated from the interior of the carriage, grips the central cograil and slows the descent when necessary. The usual brake applied to the rim of the cogwheel itself has here been discarded as expensive and unsatisfactory. The ordinary side-rails are by Herr Stumm, of Neunkirche, the cograils coming from the factory of L. von Roll.

The power destined to propel the rolling stock is more interesting from an electrical than from a hydraulic standpoint. Curiously enough, in Swiss rivers, the flow of water may be said to vary happily in proportion to the number of visitors to Switzerland. In other words, it is during the hottest months of the year, when summer drives all good people away to the mountains, that the melting snows of the Bernese Oberland contribute most generously to the Lauterbrunnen torrent.

The mechanical requirements for the railway are fixed at 500 h. p., amply sufficient to pull a train of 80 passengers up a 25 per cent. gradient at a speed of 8.5 kilometres an hour. The losses in power along the line, that is, between dynamo and motor, are estimated as follows:

Motor, total efficiency.................. 90 per cent.
Transformers, total efficiency .... 84 "
Conductors, total efficiency.............. 92 "
Dynamo, total efficiency................ 93 "

Making altogether a total loss of about 50 per cent. This brings the 212 h. p. originally required up to 424—which is exactly the work to be done at the shaft of the turbine.

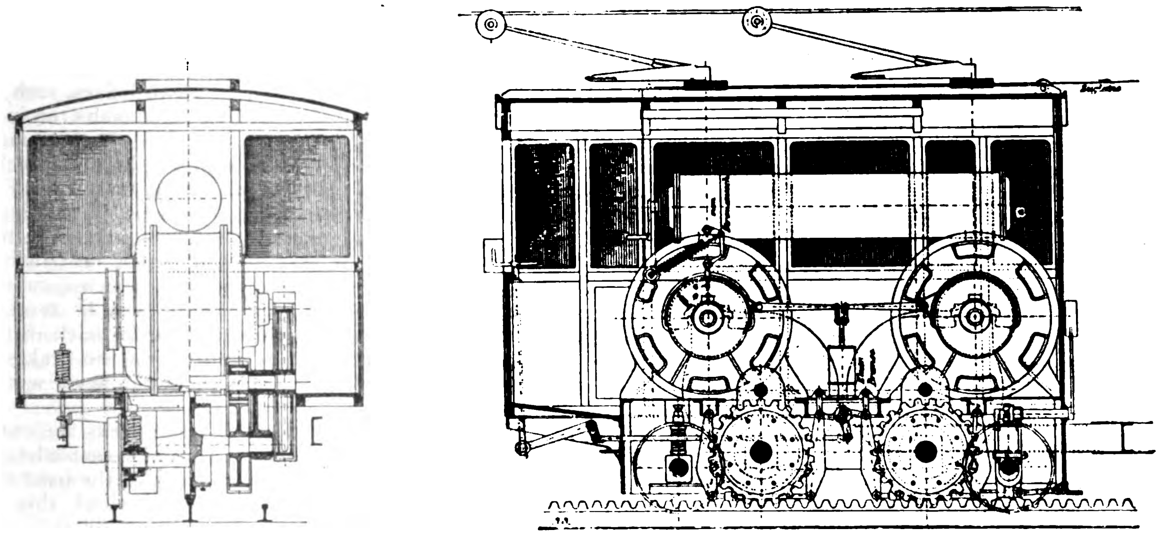
For the lighting of the tunnels separate wires are to be run, and to guard against irregularities, a set of accumulators are to be established at every station. It seems likely that many people, not caring to make the entire ascent, will patronize the railway only as far as the first and second stations, between which, as a result, the train-traffic will have to be increased. An allowance of power for four trains ascending simultaneously has therefore been made. This brings the total of h. p. required up to 2,130.

An aqueduct of 1,315 metres length conducts the water to the turbines. These are four in number, two of 500 h. p. each, and two smaller ones of 25 h. p. each; these serve to work the exciters for the dynamos.

The following are some technical data concerning the installation: Effective fall of water, 35.0 metres; volume per second, 1,430 litres. The cost is reckoned as follows:

	Francs.
Groundwork, foundations, etc.	19,000
Aqueducts, Section 1	147,500
Aqueducts, Section 2	107,300
Turbines and dynamos	230,000
Sundries	55,000
Total	558,000

Electricians have, almost without exception, recommended alternating currents as working most economically for long distances. Two alternative current dynamos are coupled direct to the shafts of the two larger turbines, of 7,000 volts E.M.F. each. The two smaller turbines work the continuous-current exciters, which, as I already mentioned, are of 25 h. p. each.



RACK RAIL ELECTRIC LOCOMOTIVE, JUNGFRAU ROAD.

From the station at Lauterbrunnen, the conductors lead across the slopes of Wengen to the station at the Scheidegg, where transformers reduce the original electromotive force down to 500 volts, the originally-planned 700 volt lines not having, for some reason or other, appeared sufficiently safe to the railway committee. As has been stated, the maximum number of trains following one another is reckoned at four. The electric locomotive is the most powerful yet made on any railway in the world for light railroads. It is from the Swiss Locomotive-Fabrik, and is constructed to carry two motors of 150 h. p. each, whose power is transmitted to the driving-shafts by cog-gearing. The whole is made of cast steel, with the exception of the motor-shafts, which are of a bronze-aluminum alloy.

The engines are fitted with an automatic electric brake, constructed somewhat on the principle of the well-known safety-plug. When the current becomes too strong the "brake" steps in and reduces it down to reasonable proportions. The hydraulic and electrical works have been partially undertaken by Reiter & Co., also by Escher & Wyss, the Oerlikon factory has supplied the dynamos, the Berne iron foundry the trucks and carriage frames.

Brooklyn Bridge Trolley Register.

The electrical device for counting the number of trolley cars that cross the Brooklyn Bridge in connection with the through transit scheme, has been completed by Electrical Engineer C. B. Martin. Under the terms of the contract made by the old board of bridge trustees, a toll of five cents is to be paid for every trolley car that makes the round trip on the bridge, and 12 cents for every elevated car.

The electrical device adopted for counting the trolley cars is the invention of Engineer C. B. Martin, who is in charge of the electrical department of the bridge. The device is one that cannot possibly be beaten by the trolleys, and Mr. Martin is confident that every car crossing the bridge will be recorded. Two of these instruments will be used, one on each roadway, in front of the toll collector. While it is expected that the instrument will record correctly, a three months' trial will be made before it is adopted, and during this period each instrument will be a check on the other, and, in addition, a count will be made by men stationed on the bridge for this purpose. According to the present programme the trolley roads expect to operate cars to the number of 3,000 to 5,000 trips per day. This will give the bridge a revenue of between $150 and $250 per day. The elevated cars, when they finally succeed in completing preparations, are expected to run over the bridge daily to the extent of 2,000 single car trips, or a daily bridge revenue, at 12 cents per car, of $240. The yearly revenue of the bridge from all tolls from cars, it is estimated, will be in the neighborhood of $150,000.

The electrical counting device for trolley cars is primarily based on the use of a series magnet introduced in a special feed wire to an insulated section of the regular trolley wire.

This insulated section is 60 feet long and is supplied from the main feeder by a wire which is coiled into a solenoid. This solenoid operates the arm of the counter every time current is taken by a car passing this 60 foot section. The counter consists of a series of cogwheels which move forward one inch, and this shows that one car has passed over the bridge and one five cent toll is due from the railroads. By a connection with the first counter, the cogwheels in the second counter situated in the main office are set in motion at the same time, and in this way two records are kept by each instrument of every car that passes this point. One counter of each instrument will be placed on the roadway, and probably in the toll collector's box, where he can instantly see that it registers every car that passes him.

An English Post-Office Electric Mail Wagon.

THE London Electrical Cab Company, under contract with the Post Office have been running a mail wagon between the General Post Office and Paddington since the month of January. Between these terminal points two calls have to be made, one at the West Central Office, and the other at the Western District Office. Six journeys per day are made, representing a total distance of 35 miles. The total weight of mails carried is, of course, very variable, but it frequently exceeds a ton. "The Electrician," London, gives the following description of the wagon and its equipment, as illustrated:

The cells used are of the E. P. S. Faure-King type, specially made for this purpose. Each cell is 6¼ inches square in plan, and 10 inches high, and contains 11 plates which have a capacity of 172 ampere hours at a discharge rate of 30 amperes. Forty such cells are used, always in series, giving a pressure of about 80 volts. The cells are carried in a single tray, which is slung under the bottom of the van by four suspension links supported from the body of the van by helical springs under compression. The total weight of the battery is about 13 cwt. Through hinged doors in the floor of the interior of the van the motor is easily accessible. The latter is of the Johnson-Lundell two-pole ironclad type, in which the field winding surrounds the armature. This type of motor the company find to be more efficient than the four-pole type hitherto used in their cabs.

There are two armature windings, two commutators, and two series field windings on each motor. The brushes are of carbon, fed end-on to the commutator by a simple flat spring. The capacity of the motor is about 3½ h. p., and the mean working current about 30 amperes. On the armature spindle is a rawhide pinion having 20 teeth, which gears into the central wheel of the differential gear, this wheel being provided with 62 teeth.

LONDON ELECTRIC POST OFFICE VAN.

To provide for the different speeds of the driving wheels in negotiating curves, the countershaft is in two halves, each half being driven by a differential gear. These countershafts run in self-aligning bearings, and each carries a sprocket-wheel having 18 teeth. Sprocket-chains connect these with the larger sprocket-wheels fixed to the driving wheels, and bearing 120 teeth. Finally, the diameter of these rear or driving wheels is 3 feet 6 inches. The many difficulties encountered in the tires have been met by the use of solid round rubber tires of small cross-section. The controller admits of five combinations, which secures different speeds and tractive force. The motor may be reversed at the slow speed by placing the regulator handle back of the neutral or top notch. The action of putting on the brakes also puts the motor out of circuit, so that the latter never works against the brake.

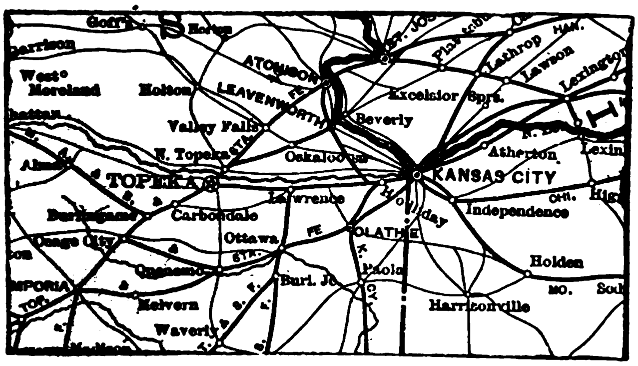
A key is provided by which alone the cells are connected to the regulator, and by which the driver is enabled to leave the van "out of gear." The turntable, to which the front two wheels are attached, is provided with a toothed wheel; this gears into a pinion on a vertical spindle, on the upper end of which is fitted a worm-wheel gearing into a worm operated by the driver's steering wheel. It may be added that the laminated type of sprocket-chain hitherto used on the cabs is being replaced by a chain closely resembling the ordinary bicycle sprocket-chain.

The accompanying illustration gives a view of the mail wagon. The daily service of six journeys is performed with one battery charge, and has, so far, been characterized by perfect punc-

tuality—an essential feature in a mail service. The maximum speed of the van is from 10 to 11 miles per hour on the level road.

Two Important Electric Roads For Kansas.

ONE of the most important newer manufacturing centres of the West is Kansas City, Mo., located on the Missouri River, on the border line between the States of Missouri and Kansas. Surrounded as it is by numerous smaller towns with flourishing trades and markets, and located in a great farming district and near the City of Topeka, shown by the accompanying map, it seems but natural that capitalists are realizing the importance of electric roads to connect Kansas City with its surrounding territory. Recently a company has been formed, with Mr. D. A. McKibben, of Leavenworth, a wealthy capitalist, at its head, which contemplates the construction of an electric railroad between Kansas City and the cities of Topeka and Leavenworth. The road between Kansas City and Leavenworth will curve considerably to the west with two objects in view: one to reach a beautiful farming country, the road passing very near the soldiers' home; the other to avoid two or three steam roads on the west side of the Missouri River. The Leavenworth company contemplated placing their power house at the coal mines in Leavenworth, but this may be abandoned and a greater power



MAP SHOWING THE LOCATION OF KANSAS CITY, TOPEKA AND LEAVENWORTH.

house be erected in Kansas City, Kansas, on the north bank of the Kansas River, and the company will then be able to furnish power to the Metropolitan Street Ry. Co., of Kansas City, Mo., as well as to their own line. By making the curve mentioned they will be able to take in en route, Bonner Springs, which is rapidly becoming known as a health resort.

The Kansas City & Topeka Electric Ry. will build on the south side of the Kansas River, a distance of 60 miles, and it will almost parallel the Atchison, Topeka & Santa Fé Ry., between these cities. There is a very large local trade in farm produce, such as garden truck, butter and eggs, as well as milk, along the entire route, and the steam roads cannot supply this community with facilities for reaching the city at the time needed to dispose of their produce. The electric company propose doing this and will enter upon a great traffic as soon as the road is completed. The power house will be located at Lawrence, and the power will be derived from the water of the Kansas River, which is dammed at Lawrence. They will have an abundance of water power at that point, and it is possible that they may use the dam also at Topeka. An endeavor is being made to get this company, which has ample backing, to use the Leffler system, which was used at Lincoln Park, Chicago, and, while it is operated without an overhead trolley and by the alternating current, has proved very successful. The right of way between Kansas City and Lawrence is mostly provided for and building will commence in early spring. We are indebted to Mr. D. A. Williams, of Kansas City, for the above information.

The Trolley On The Brooklyn Bridge.

THE Brooklyn trolley cars are now running across the bridge to the great satisfaction of the residents of that city who do business in New York. On the morning of February 16 five of the principal lines began making trips under short headway and soon the lines from all parts of the city converging at the bridge will include it in their routes. The time taken to run across is about seven minutes. As the cars approach the New York terminal they are met by two guards who prevent egress therefrom until each has stopped and emptied. After this short interval the new passengers are taken aboard and it is at once started on the return trip in much less time than are the cable cars.

Supt. Martin of the bridge is quoted as saying that by this means the car carrying capacity will be increased 17,000 per hour, or nearly doubled. The bridge trains of cable cars are already much less crowded.

The arrangement of the New York terminal loops has been the subject of much sensational opposition by certain of the yellow dailies, and the horrors of "the latest death-trap" have been tragically depicted. The unprejudiced observer must admit, however, that the danger to pedestrians is no greater than that incurred in crossing any crowded thoroughfare, and of which nothing is thought.

The Philadelphia Gas Works.

BY W. E. DODGE.

IN The Electrical Engineer of Nov. 18, 1897, was the statement that "the gas plant of Philadelphia has been operated on a basis of heavy net loss, and for a long time past has been buying gas from private plants to sell again." It is all right for The Engineer to advocate corporate or private ownership as against municipal, but I submit that it should be careful to not misrepresent the facts. According to the official report of the Director of Public Works, the Bureau of Gas in Philadelphia, from 1891 to 1894, inclusive, had a total expenditure of $10,858,910.58, and for extension of the plant and permanent improvements, $1,050,248.81, a total of $11,909,159.39. During the same time, there was turned into the city revenues from the gas, $14,790,404.25, or nearly three millions in excess of the entire expenses, and that, too, notwithstanding that the price of gas was reduced in 1894 to $1, or 33 per cent.

During the same time gas was furnished free for all the municipal buildings and for street lighting, to the amount of $3,299,122, besides. In fact it was more than that, for in this calculation the gas is put at $1 per 1,000, while for three out of the four years it sold for more than that. It will thus be seen that during those four years the profit to the city was $6,180,366.86—an average of $1,545,091.71. per annum.

I have not the figures for 1895, but for 1896 the official report shows that in addition to the erection of new street lamps, and paying for 224,125 feet of additional mains, the gas works paid into the city revenues $352,988.80, besides furnishing for city use, gas to the amount of $674,031.51, or a total of $1,027,020.31. It is fair to presume that for 1895 the profit was as great, if not greater; and if so, then the profit to the city for the past six years has been $8,234,407.48.

It is true that for some eight or nine years past the city has bought gas of a company which built its works under the control of the city engineer, but that was simply because the city gas works could not supply the city and the suburban demands; and the fact that this private company could build its plant and then sell its gas to the city for 37½ cents per 1,000, and make a profit on its investment, shows how very profitable the gas business is.

It is further shown by the efforts of outside parties to buy or otherwise get control of the gas works, some having offered $25,000,000 and others $30,000,000 for them. Why, if not profitable?

An ordinance has been passed by which the gas works are to be leased to a company for thirty years, with the right reserved by the city to terminate the lease in ten years, and by which the company is to furnish gas free for the public buildings and the street lamps, and to the citizens at $1, with the right of the city to reduce the price after 1907 to 90 cents; from January, 1908, to 85 cents; from January, 1913, to 80 cents, and from January, 1918, to 75 cents per 1,000. The gas is to be of not less than 22 candle power.

In addition, the company agrees to invest $5,000,000 in improving and extending the works within three years, and thereafter not less than $10,000,000 more, or $15,000,000 in all, during its lease of 30 years.

The company is to pay to the city on all gas sold prior to 1908, all that it receives over and above 90 cents per 1,000; on all it sells from December, 1907, to January, 1913; all it receives over 85 cents to 1918; all over 80 cents to 1928; all it receives over 75 cents per 1,000, the city reserving the right to change the price of gas at its pleasure. The company is also to put in service pipes and gas meters for private consumers at its own expense.

Whether the city will make more profit by this arrangement remains to be seen, but there can be no question that the ownership of the gas works has proven profitable, notwithstanding the alleged reckless and extravagant mismanagement under city control. If profitable under such control, how much more so might they have been under proper control.

I am aware that the whole contention in favor of private, as against municipal control, is that under municipal control they cannot, or will not, be honestly and economically managed. Such an argument is not creditable to us as a people, and I admit that where municipal works are run by politicians, or in the interest of political parties, there will be extravagance, if not corruption and waste. But why need they be so run? The remedy for that lies in having them run by a non-political commission or board, which shall be permanent, and be retained during good behavior.

We are far behind European cities in our management of municipal affairs, but there is an awakening of the public all over the country on this subject, that sooner or later will put us on a par with them, in that respect.

Mismanagement of Philadelphia's Water Supply.

A severe arraignment of the mismanagement and neglect in Philadelphia in the matter of water supply was presented at a recent hearing before a committee of the Council. The occasion for the hearing was the public demand that something be done to remedy the conditions because of which the city is disgraced by an epidemic of typhoid fever. It was shown that the prevalence of fever in the city is far in excess of any other city of like rank in the world, and that the cause is the contamination of the streams from which the city draws its water supply; and it was pointed out that, basing an estimate upon the statistics of the Board of Health for the ten years ending December 31, 1897, which show the total mortality from typhoid fever in Philadelphia during that time to have been somewhat over 5,000 deaths, representing about 50,000 cases of sickness, and estimating the pecuniary loss from each death to have been $1,000, and from each case of sickness to have been $100, the citizens of Philadelphia have in that time suffered a money loss of some $10,000,000, which could have been absolutely prevented by filtration of the water. This would not only have paid for filtering the water supply, but would also have prevented all this disease and death. An irreverent Philadelphian asked once to describe the drinking water furnished by the city, said it was the kind Christ walked upon.

Municipal Electric Lighting.[1]—I.

BY PROF. JOHN R. COMMONS.

IN advocating municipal electric lighting I accept the burden of proof. I agree that government, whether national or local, cannot safely undertake experiments on a large scale. The assumption of new functions must be shown to be not merely desirable in the interests of a few, or adapted to the doctrinaire ideal of a well-rounded form of government, but it must be shown to be necessary and essential for the preservation of important interests affecting the welfare of the entire body of the people. Governments do indeed enter upon experiments, and the assumption of a well-established industry may itself be called an experiment. But in the sense in which I use the word, the introduction of new modes of manufacture or service and the creation of new wants among the people are matters involving risks of an incalculable and speculative kind, and this is not the business of government. Private parties should be encouraged to push forward in all the untried fields. If their ventures are unsuccessful, if they are ahead of their times, failure and bankruptcy will affect only them and their immediate dependents. Successors will come in, and if the service in question meets a truly growing need of the people, success and fortune will follow. But if government ventures upon the sea of uncertainty, bankruptcy means the beginning of anarchy. Government does not perish like the individual or the corporation, and failure on a large scale, if it involves repudiation or oppressive taxation for years to come, produces a popular revulsion and deep-seated distrust of government itself in all its departments.

A criticism should be made upon those cities which entered upon municipal electric lighting eight or ten years ago. Here was a new agency utterly unknown as a commercial quantity; new machinery of all degrees of imperfection and uncertainty; cost of operation, depreciation, risks, unsettled; engineering and mechanical requisites on the part of employés quite indefinite; public opinion not yet crystallized through adequate discussion and experience. In face of all these uncertainties, it would not be strange if many cities have incurred debts for fabulously priced machinery which a few years of experience have since discarded, and if the reaction has driven the citizens to the best kind of a bargain they could make with private companies. It is reported that eight or ten towns and cities which had installed municipal plants have abandoned their undertakings and sold out to private companies at a serious loss. That the number is so small, considering that nearly three hundred cities and villages have adopted municipal ownership, certainly speaks well for the industrial ability of our small cities. On the other hand, the fact that these failures have not prevented an astonishing increase in the number of municipal plants indicates some deep-seated causes which are worthy of our attention. In the State of New York alone, the six municipal plants of two years ago are now increased to twelve and possibly more.

MUNICIPAL FUNCTIONS INCREASING.

Municipal functions have increased very slowly. Cities have accepted the principle, just as every advocate must also do, that the burden of proof is against the assumption of new functions. Natural lethargy and difficulties in the way of co-operative action have been important checks, but equally or more important has been that wise Anglo-Saxon conservatism which makes sure and impregnable every acquisition in civilization before advancing to new fields. In the matter of electric lighting only weighty and even vital considerations can push forward the movement for municipal ownership over any extensive range of cities. As far, however, as the experimental character of the industry is concerned, fifteen years of experience and marvelous inventive progress have reduced electric lighting to a system and made all its parts and details as readily calculable as any of the functions in which cities are now engaged. The rapid growth of cities themselves with an assured increase of demand for light and power, combined with the perfection of the mechanical equipment, and the fairly reasonable competition between producers of the same, have removed for the present the weight of any criticism similar to that which might attach to those cities which ventured upon this field in the early days of the industry. The questions which now present themselves to cities considering the proposed operation of municipal plants are, therefore, greatly simplified by the elimination of these strictly mechanical questions. The new problems are of a quite different character. They may be briefly summarized under the headings—improved service, diffusion of use, stimulation of industry and purification of politics. These apply to all industries requiring a municipal franchise, and with the growth of a city, anyone or all of them may gather such increasing weight that the city is compelled to assume the operation of the industry in question. Streets and alleys have, of course, long since been municipalized, and it would be utterly intolerable even in small villages if vehicles and horses were subjected to tolls at various street intersections. The sewerage system comes next in urgency. Only three cities in the United States have private-owned systems of sewers. This service must be made universal and must be of the highest quality for both poor and rich sections. It, therefore, like the streets, has been municipalized and made entirely free of tolls. New Orleans with its private sewers is suffering not only from inadequate sewer service, but from corrupt politics growing out of such service. Water-works follow sewers in the extent of municipalization.

[1] Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec. Engr.

MUNICIPAL LIGHTING SUCCESSFUL IN SMALL CITIES.

In electric lighting the process of municipalization is as yet mainly in the small places. While but three cities over 100,000, according to the census of 1890, have municipal electric plants, it appears from the list of sixty-four cities with municipal plants, as given by Mr. Francisco,[1] that twenty-nine have less than 5,000 population, nineteen from 5,000 to 10,000, making a total of forty-eight, or three-fourths, under 10,000, and fourteen range from 10,000 to 50,000. The fact that the preponderance lies so largely on the side of the small cities and villages is sometimes advanced as showing that large cities are not competent to undertake this function. While such a conclusion is, of course, not logically warranted, there are patent reasons why municipal ownership should achieve its first success in the smaller municipalities. Here, as I have already said, government lies close to the people. The officials are known to every one. They cannot retire under the shield of their friends and party councillors. They are accessible to the personal complaints of every one. In large cities newspapers do the complaining, and everybody discounts these as the organs of partisanship or corporate jobbery. The people do not come in contact with their officials. But it is otherwise in the small cities, and the result is a constant effort on the part of officials to meet the demand for efficiency and economy.

The voting constituency, too, has a preponderance of small property owners, the thrifty and independent middle class, who have always been the bulwark of popular government. There are no multi-millionaires on the one hand and no overwhelming array of wage-workers dependent upon them upon the other. This relieves the community both from the machinations of a few rich men who in every city use their power to exploit their neighbors, and whose interests are, therefore, against honest government; and also from the blind struggles of the working classes to secure through politics those advantages and liberties which they are unable to obtain in industry. This makes both the administration of the civil service a simple matter, and the hours and wages of labor in public employment conform to the most exacting conditions that obtain in private industry.

Below is a table showing for street plants in large and small cities, the varying costs of labor per arc light for public and private plants.

TABLE I.

Cost of Labor per Arc Light.

1. Labor Employed, 72—84 Hours per Week with Water Works Plant.

	Arcs.	Per year.	Per lamp hour.	Authorities.
Dunkirk, N. Y......	75-2000	$a12.18 b12.95	$a.0039 b.0044	a Computed, '97, b Foster.

A Toronto Report Adverse To Munucipal Ownership.

At a meeting of the City Council's special committee on electric lighting, Engineer Rust was summoned to give the probable cost of installing a civic plant, and said it would reach for all the municipal lighting perhaps $400,000. They would need 2,000 h. p. There are at least 1,100 street lights of one horse-power each, and the new municipal buildings will take 4,000 incandescent lights. The plant for commercial purposes would cost $103,000, and it is not likely that the city would be able to reduce the rates now current. He estimated the cost per street light as only 5 cents less than the Toronto Electric Light Company is now charging.

The mayor thought that it was beyond the city to put up buildings and go into the supply of electrical energy. There was a vast storehouse of energy not far away at Niagara. Surely the company there would be able to supply Toronto with energy more cheaply than the city could manufacture it from coal. He expected to have reliable information from that company himself. No action was taken.

[1] "Municipal Ownership; Its Fallacy," p. 39.

The Municipal Plant at Emporia, Kan.

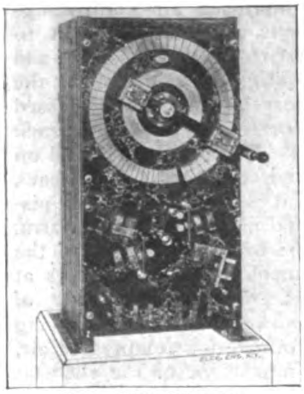
A reader at Reading, Kan., sends us the accompanying newspaper item as to the municipal plant at Emporia, Kan.:

"Councilman Weyler said some time ago that he thought the city would save about $1,800 in six months by owning the electric light plant. According to the figures in the city clerk's books, the expense account for the five months, during which the city has owned the electric light system is as follows: 'September, $537.94; October, $407.98; November, $572.49; December, $561.77; January, $797.43; total, $2,877.61, or an average for each month of $575.52. The city has received during this time $335 for lights. When the city rented the fifty-six and fifty-seven lights it paid from $504 to $513 a month for them. The $1,800 that it was thought the city had saved does not appear on the books."

Our correspondent adds that he understands, in addition, that the city of Emporia has a debt of $17,000 on a second hand plant.

OSAGE CITY, KANS., is to vote on the purchase of the private plant there, and the municipal running of same. The city is to pay $2,500 a year for three years, and then own the plant outright.

Electrical Control and Operation of Newspaper Presses in the News and Record Office, Chicago.



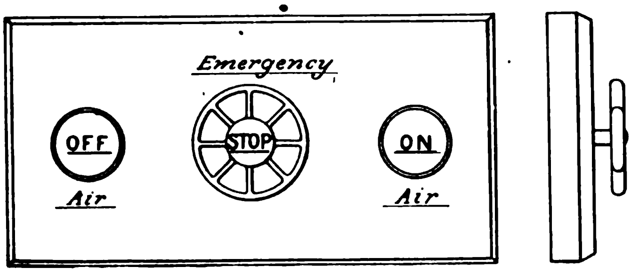
Controlling Rheostat.

THE publishers of the two great Chicago dailies, the Chicago "Record" (morning), and the Chicago "Daily News" (evening), will, on February 23—just before this article appears—dedicate a new press room. As a matter of course electricity plays the important part of furnishing motive power for the two presses in this room, as electric motor drive is indispensable to a strictly up-to-date press room, and in fact its use for this purpose has almost ceased to be a novelty.

The principal interesting feature of the "Daily News" plant, to the electrical engineer, is the method of control, which differs from anything previously employed in several respects, and presents several refinements not heretofore used. The credit for the perfection of the plant is due to Irving Stone, mechanical engineer of the "News" and "Record" properties, and one of the leading specialists in daily newspaper engineering in the country. He had also, at the time the plant was installed, the active co-operation of the Gibbs Motor Company, of which Kohler Brothers were the Chicago agents, and the Cutler-Hammer Manufacturing Co., which furnished the electrical controlling apparatus. The Gibbs Company was recently absorbed, we understand, by the Westinghouse Electric Manufacturing Company.

The new press room, although only now formally opened, has been in actual daily service for some time. It contains two large Hoe newspaper presses, each with a capacity of 22,000 per hour. The floor of the press room proper is on a level with the street. Under the presses is a light, roomy basement where the paper reels and electric motors are located. Quick communication between the basement and press floors is afforded by automatic compressed air man elevators for going up, and poles for sliding down. The latter are a familiar sight around fire engine houses. The former are a novelty both in press rooms and elsewhere. An elevator consists of a round plate large enough for one man to stand on, operated by compressed air, acting against a piston from below. When a man steps on one of these plates (which is located in a shaft running up to the next floor), his weight automatically trips an air valve and after a fraction of a second he is shot up to the next floor, where he immediately steps off and the plate slowly returns to the bottom ready for the next comer. A small compressed air plate elevator is also used.

The main motors driving the presses are put on a built-up foundation under each press and are directly geared to the presses. Each press has a 220 volt motor of 40 h. p. furnished by Kohler Bros. Attached to the basement ceiling under each press is also a small shunt-wound motor, for running the press slowly when making ready. This small motor is governed by a rheostat to run from 160 to 210 revolutions per minute, and at the latter speed develops about five h. p. It is worm geared to the driving shaft of the press; whereas the main 40 h. p. motor



FRONT OF JOHNSON MOTOR CONTROLLER.

is conected to the same shaft by spur-gearing. A clutch working on the principle of a ratchet is put between the worm gear and the driving shaft of the press, so that when the large motor is turned on it does not drag the small worm-geared motor along with it, but leaves it free to be shut down whenever the press speed exceeds that of the small motor.

The controlling rheostats of both large and small motors are worked by compressed air, and compressed air controlling-handles are placed at numerous points around each press to afford convenient and instantaneous control both for service and emergency purposes. The accompanying engraving shows the rheostat for one of the 40 h. p. motors before the compressed air appliances were put on. The rheostat is worked by a rack and pinion and air cylinder at the back. The pinion is placed on the shaft of the rheostat which extends out through the back of the case and the rack which turns it is connected to the piston of the compressed air cylinder. To move the rheostat arm, air pressure is let into one end of the cylinder and out of the other. The air is controlled by Johnson motor controllers at numerous places around the presses. The arrangement of pushes on these press controllers is shown in the accompanying sketch. The pushes marked on and off are for compressed air, and when used give a rather slow movement of the rheostat handle. The middle push is an electrical contact for instantaneously stopping the press in emergency cases. This is done as follows: The catch, with a magnetic trip, which is shown at the right hand lower corner of the front of the rheostat, holds the contact lever switch normally at off position, as in the engraving. The trip magnet is worked by a battery circuit and can be operated from any of the controller middle push buttons. Closing the trip magnet circuit makes the catch let go of the circuit breaking contact arm, and it flies into the reverse position from that shown in the engraving, shutting off the connection of the motor with the line and closing its armature circuit through a resistance, so that it acts as a dynamo to make an electric brake. A quick stop is often important with one of these presses, on account of the speed at which they run and the rapidity with which trouble piles up when a sheet breaks or other mishap occurs. As soon as the circuit breaker acts, in addition to opening the circuit and making an electric brake of the motor, it trips an air valve, which causes the rheostat arm to return to "off" position. As soon as the rheostat arm has reached "off" position another air valve is tripped by it which operates a piston which resets the circuit breaker arm, so that the whole apparatus is ready to go ahead again within a few seconds of the time an emergency stop has been made and no attention from the pressmen is needed. No automatic device for opening the circuit when the current supply is shut off accidentally is considered necessary here, because the pressmen are always on the alert to notice any slight slowing down of a press and always shut off power instantly whenever it occurs, so as to prevent any possible accident due to something going wrong with the press. Their watchfulness to protect the press thus serves the double purpose of protecting themselves and the electrical apparatus.

The fields of the 40 h. p. motors are compound wound, and provision is made on the last few segments of the rheostat to short circuit some of the series turns to increase the speed. The controlling rheostats for the two presses are placed upon a high platform in one corner of the press room, and being operated by compressed air and electricity, it is not intended that they shall ever be touched except for cleaning and repairs.

Mr. Stone has provided a very useful little device for automatically stopping a press whenever a sheet breaks or loses its tension, and thus saving costly accidents. One of the rollers around which the paper passes on its rapid journey into the press is held in position by the tension of the paper which passes around it. Should a sheet tear this roller would fall away from its normal position and make an electrical contact which would stop the press without waiting for a pressman to do so. This is done very simply and easily with the method of electrical control employed.

In addition to the rheostats of the type shown in the engraving, there are, of course, double pole switches in the main supply circuits. Current is taken either from the Edison street mains or the "Record's" own plant. It is expected to enlarge this latter and eventually use electric drive throughout.

ELECTRIC LIGHTING

Memorandum on Mr. W. S. Barstow's "Load Factor System of Charging for Electrical Energy."

BY WILLIAM A. MOSSCROP, M. E.

A VERY serious error will be found in the method of apportioning the cost of fixed expenses per kilowatt hour to the different hours of the day as it was described in Mr. Barstow's article, entitled "Load Factor System of Charging for Electrical Energy," printed in The Electrical Eingineer of Jan. 13, 1898.

As an illustration of the effect of the error's correction on the results, it may be pointed out that taking values from Fig. 2 of the article[1], the cost of fixed expenses per kilowatt hour at 8 p. m. will be nearer 7 cents than 20. The minimum rate, however, would not be affected by the correction but would remain as shown in Fig. 2 of the article.

At 8 p. m. the charge proposed to be made against a customer to cover the cost of fixed expenses per kilowatt hour is taken from the dotted line in Fig. 2; it equals 20 cents and it is proposed to make this charge for each and every kilowatt sold at this hour.

Reference to the rules laid down in the article will make it clear that this charge should be made only against the kilowatts found in block J at the top of Fig. 1. And that in block A at the bottom of Fig. 1, the cost of fixed expenses per kilowatt hour at 8 p. m. will be the same as at 7 a. m. From Fig. 2 it will be found to be only about 1.7 cents. Each intermediate block, at this hour, will have its own cost of fixed expenses per kilowatt hour, as determined by the rules laid down in the article.

The generating station would experience some difficulty in

[1]The figures referred to have been reproduced for convenience.

determining who was using current at 8 p. m. in each of the blocks. Therefore, in order to fix a just charge per hour for

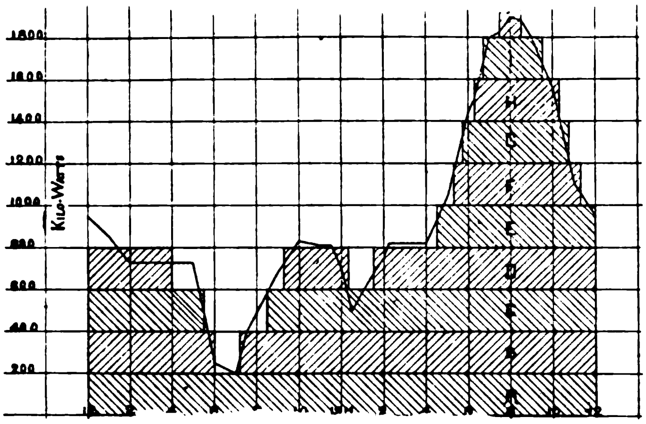


FIG. 1.—AVERAGE LOAD CURVE.

each and every kilowatt sold at 8 p. m., it will be necessary to average the costs in every block at this hour.

To obtain the charge at any other hour, it will be necessary to average the costs in the proper number of blocks as deter-

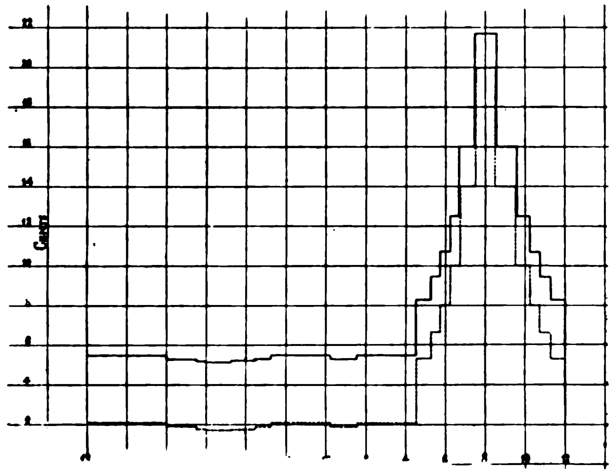

FIG. 2.—AVERAGE EXPENSE CURVE.
Dotted line shows fixed expenses. Solid line shows total expenses.

mined by the load on the station at the hour for which the charge is desired.

Electric Lighting on the Diamond Shoal Light-Ship.

LIGHTSHIP No. 69 has now been anchored on the dangerous Diamond Shoal off Cape Hatteras in 30 fathoms for three months, and having ridden through the gales that prevail off that perilous spot on the Atlantic in entire safety during the roughest weather, has proved to the satisfaction of the Lighthouse Board that a light vessel can safely be maintained there. The captains have now become familiar with the light, and until the ship is replaced by a lighthouse as originally intended, she will be a beacon to be carefully watched for and avoided.

Nos. 68 and 69 are sister steamships built at the yards of the Bath Iron Works, at Bath, Me. No. 68 is the lightship off Fire Island. Both 68 and 69 are unusually powerful composite vessels, 122 ft. 10 in. long over all, 29 ft. 6 in. extreme beam, and 22 ft. moulded depth. They are provided with propelling machinery to enable them to steam to their stations, and, also in case of necessity, to steam away from their dangerous positions. The engines are simple condensing vertical, with a cylinder 20 inches in diameter and 22 inch stroke, developing 350 h. p. at 150 revolutions. Steam is furnished at 100 pounds pressure by a steel Scotch boiler 12 ft. 2 in. in diameter and 11 ft. long. Two vertical donkey boilers furnish steam for the electric lighting plant, windlass, pumps, fog signals and for heating. The vessels are also fitted with steam steering gear, bells, a steam winch and full equipment of anchors and chain cables.

The two masts are of steel; each exclusive of the flag pole 64½ feet high. The electric lights are suspended at the mast heads, and are surrounded by a gallery for day signals.

To avoid chance of breakdown the electric plant on each vessel is in duplicate. Each plant consists of two marine gene-

FIG. 1.—DIAMOND SHOAL LIGHT SHIP.

rating sets with dynamo and engine both built by the General Electric Company of Schenectady, N. Y. The four pole dynamos are 8 kilowatt 650 revolution machines, directly connected to 4½ in. x 4 in. double cylinder engines. The switchboards are of Vermont marble, and the wiring appliances used throughout are of the type approved by the U. S. Naval Board of Inspection. The dynamos furnish 100-volt current to eight 100 candle power lamps, four at each masthead, and forty 16 candle power lamps throughout the vessel. The masthead lights are each enclosed in a lens lantern, three being used and the fourth held in reserve. Connected in circuit to the masthead lights is a device making and breaking the circuit and lighting and extinguishing the lamps at regular intervals. A fixed white light shows for twelve seconds and is followed by an eclipse of three seconds. The focal plane of the lights is 57 feet above

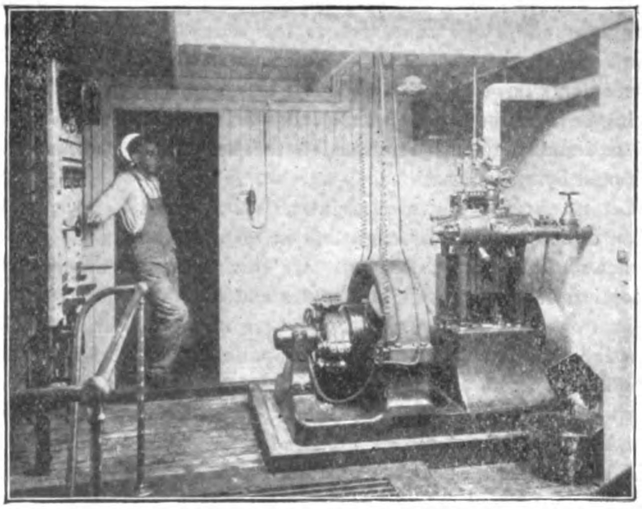

FIG. 2.—DIAMOND SHOAL LIGHT SHIP, DYNAMO ROOM.

the sea, and they will be visible thirteen nautical miles away in clear weather. Great reliance is placed upon the electric plants and in their construction more than ordinary care has been taken. We are indebted to the courtesy of the New York "Tribune" for the photographs from which the illustrations were made.

VOL. XXV. NEW YORK, FEBRUARY 24, 1898. No. 512.

Standardizing the Electrical Industry.

ANY industry which has been sufficiently developed to permit of a universal adoption of standards and the compilation of a vocabulary may be said to have reached that stage of perfection which makes possible an international interchange of its products and facilitates their introduction into the workshops and homes of the people. To effect standardization and a harmony of speech and customs among the nations of the earth, as far as differences of climatic conditions, surroundings and government would permit, have been the desires and earnest efforts of humanity from time immemorial. The tower of Babel was never completed because its builders lost their common standards. Since that time every success of human enterprise can be traced to a union of forces, a union of thought and a unanimity of purpose. Again and again fruitless attempts have been made to introduce a universal language, to have the metric system adopted by all civilized nations, to get one value for the pound and the horse-power, and only lately did the international postal congress adopt the same colors for stamps to represent the same values throughout the world. All these international agreements have to pass through a natural course of evolution, being born in the mind of some individual, indorsed by societies of national repute, recommended to the various nations and adopted by an international Congress.

Let us turn to our own electrical sphere, and see what has been done by electrical engineers in bringing about the standardization of their profession. By this we mean the general adoption of units, words, laws, rules and diagrams, and a standardization of machinery. We must here necessarily draw a distinction between international, national and local or municipal standards, and not attempt to effect international agreement of matters which are governed solely by national or municipal conditions. The electrical units, after years of patient labor and the meetings of numerous congresses, have at last received names, values and definitions by international agreement. The laws governing electrical phenomena have been stated in various tongues in as many different ways, but, being subject only to facts and investigation, they are unalterable. The electrical nomenclature must needs be evolved by national custom and agreement, save the names of the units which require international sanction. The rules governing the installation of machinery, wiring, etc., have just been revised by representatives of several national societies and will soon be adopted, we expect, by the entire electrical engineering profession and its kindred interests. The standardization of electrical machinery is now under discussion and we believe will soon be disposed of in a satisfactory manner by the representative electrical body of the United States.

Thus we see that all questions which require united council and action for their final settlement have received their due attention, except the standardization of electrical diagrams. This problem has been attacked by many able men, and only a few years ago we published the splendid chart of electrical diagrams compiled by the champion of electrical standardization, Dr. F. B. Crocker, to whom much credit for much of this good work done by the electrical engineers of America is due. This chart of diagrams of Dr. Crocker has lately served as a basis for the praiseworthy work undertaken by the Chicago Electrical Association, the result of which is a complete set of standard electrical diagrams, which we publish as a supplement to this issue. The universal adoption of these simplified diagrams should follow at an early day, as the value of an easily read diagram cannot be overestimated. It educates, saves time and prevents errors, and will assist in the final triumph of electrical standardization.

Municipal Ownership and Niagara Power for Toronto.

FOR some time past the city of Toronto, Canada, has been discussing a municipal electric light plant, but at the latest official meeting on the subject, the mayor made some very sensible and level-headed remarks. An engineer's report had shown how small was the amount the city could expect to save, at the best, but the mayor pointed out that it was very absurd for the city to invest in a large power generating plant just at the moment when Niagara power might be said to be literally knocking at the door. The availability of that power for Toronto cannot be questioned, the distance between Niagara and the city being only some 75 miles. The generation of current on the Canadian shore at the Falls is cheap and easy, and the figures made by some of the leading engineers in this country, based on a potential of not more than 25,000 volts, prove that the matter has entered into "practical politics" for the progressive city on Lake Ontario. Each day, electrical engineers know better how to handle these large currents and high voltages, and Toronto can well afford to await the lapse of the few years now standing between her and Niagara power.

It will be noted that the mayor of Toronto puts the matter of a municipal plant on a commercial basis. So did Mayor Wurster, of Brooklyn, the question of city water works:

"The mayor was then asked if he believed it would be more advisable to buy the water supply for the city outright than to secure it by leasing of water privileges. In reply he said: 'It is purely a matter of business. If it can be shown that the city can buy water cheaper than the cost of pumping it then it would be profitable to buy it, for under such agreement the seller would have to deliver the water to the city. It is a purely business matter, the same as if a man in one line of business requires certain material in conducting that business. If he could buy it from a man who has a plant for manufacturing it, at a less cost than it would be for him to manufacture it himself, he would not be much of a business man if he did not avail himself of the opportunity to buy the material.'"

The commercial test is certainly as good as could be applied. There are others, but such plants must be judged by their fruits, and we must confess our inability to find other fruit, as a gen-

eral thing, than deficit, or failure, or inefficiency or obsolete apparatus, or all shortcomings mixed up together. Mr. Dodge, in our current issue, makes out a case for the Philadelphia gas works. All we will say, in comment, is that alarming figures were presented to the public before the lease of the works was made, and that amongst other items, it was shown that one man in private gas works elsewhere was expected to do comfortably the work done by eight municipal workmen in Philadelphia. In 1883 a committee of the leading citizens presented a memorial to the Pennsylvania Legislature saying: "Philadelphia is now recognized as the worst-paved and worst-cleaned city in the civilized world * * * Inefficiency, waste, badly paved and filthy streets, unwholesome and offensive water, and slovenly and costly management have been the rule for years past throughout the city government." The little statement following Mr. Dodge's article shows that pretty much the same complaint—not by us however—is made to-day. It is the same everywhere, with a steadily downward pressure, no matter how good some administrations and some individual officers may prove. Just lately, the Lighting Commission in a Western city has been standing up bravely against the desire of aldermen for more lights in their respective districts. Does anybody doubt that sooner or later, those lights or others equally needless will be strung up? The opportunity to bribe constituents in this fashion is a great temptation, and helps explain why municipal enterprises are so often costly and disastrous.

Stealing Telephone Service.

THE fine of five shillings ($1.25) may be a small one, but it is enough to mark the fact that stealing telephone service is a crime. This form of misdemeanor has just been classed in England, by the Croydon police magistrate, as petty larceny, and punished in the above manner. A young man who was the culprit used a false key to admit himself to the public telephone booths of the National Telephone Company, which he thus used without payment; and he was caught.

Perhaps if more people could be brought to understand that when they help themselves to free telephone service, they are stealing, there might be a decrease in the dishonest practice; but the trouble is, they do not stop to think about it. In a measure, the subscriber who allows the free use of his instrument is a party to the offense and is helping not only to cheat the telephone company, but to inflict poorer service on his fellow subscribers; but we all find it difficult to be ungracious when a man comes into our offices and begs to be allowed to use our telephone a moment. On the old flat rate basis, it didn't seem to matter much, anyhow, except to the company; but now when the whole telephone service is gravitating to the metred basis, the practice should stop. Indeed it is stopping automatically in offices with telephones installed on the basis of so much money for so many calls. If the subscriber wishes to be gracious he does it at his own expense, to which there is no objection.

Thermostats and the "Maine" Disaster.

FOLLOWING the anxiety and doubt caused throughout the Nation by the destruction of the U. S. battleship "Maine," we are promised a most rigid investigation by the authorities into the cause of the disaster. It is not our purpose to discuss whether the loss of the ship was due to accident or the work of some miscreant, but the accounts thus far published have served to show an apparent omission in the equipment of our war ships which appears to us serious. Granting that the explosion on board the "Maine" was due to the overheating of the magazine, caused by spontaneous combustion of coal in the adjoining coal bunkers, it would seem that precautions were not taken to ascertain the temperature of the magazine and coal bunkers at sufficiently short intervals. According to the newspaper accounts, the temperature of the magazine was taken at stated intervals during the day, but it seems only too obvious that such periodic inspections by a thermometer cannot adequately guard so vital and dangerous a portion of the ship's equipment. The most natural thing to suggest to guard against future accidents of this kind would be the placing of trustworthy thermostats in the coal bunkers and magazine. If it should appear that no device of this kind had been found satisfactory for this purpose, we are certain that very little experimenting would develop one adequate for the purpose. We know of several thermostats, which, with suitable mechanical protection, would answer the purpose perfectly. This, of course, need not stand in the way of protecting the magazine from overheating by cooling machines and similar devices employed in various navies, but a continuously acting thermostat would appear to be a sine qua non. We suggest that our naval authorities give this matter their early consideration, in order to guard against such catastrophes on our present warships. We may add that a number of vessels of our merchant marine are already protected by thermostats, as a safeguard against fire.

Electricity in the Newspaper Office.

THERE is scarcely a meeting of manufacturers or other trade association which does not find it profitable to discuss electricity in some form or another in connection with their business. This was again shown at the recent meeting of the Newspaper Publishers' Association, which met in New York last week. In discussing the mechanical work of the newspaper office the electric motor came up quite prominently, and the question put before the association was as to the most economical electric motor for newspapers, and what saving is effected by direct connection with the press and by use of low speed instead of high speed motors. There can be no question, of course, that the low speed direct connected machine will survive, for reasons which are obvious. The convenience of direct connection as against belting, added to the lower momentum of the direct connected slow speed machine, which allows of a quicker stopping of the press, will probably always decide the question in favor of the latter. We note also that the association discussed the question of employing electricity as a heating agency for the melting pots of the linotype machines in case the supply of gas should give out. We would suggest that even without waiting for the latter eventuality, the substitution of electric heat for heat by gas would be in every way desirable. Any one who has entered a printing office employing linotype machines will be struck, not to say overcome, by the noxious gases and the frightful heat prevalent in such offices. These constitute a constant menace to the health of the machine hands, and cannot fail to reduce their working capacity. We would suggest that manufacturers of electric heating apparatus look into this matter, in order to still further increase the value of the justly celebrated linotype machine.

As another feature of electrical work on newspapers we may refer to the interesting article that apears in our pages this week on the electrical control of newspaper presses. It describes the methods adopted in the "News" and "Record" offices in Chicago, and shows how far a little ingenuity will go to simplify and assist the operations of a busy printing room at the moments of greatest pressure.

MISCELLANEOUS

Conventional Electrical Diagrams.—The Chicago Electrical Association.

WE present in a double Data Sheet supplement with this issue the Conventional Electrical Diagrams embodied in the report of a special committee of the Chicago Electrical Association. The sheets can be cut up and filed for reference in the same way as our regular Data Sheets prepared by Mr. A. B. Herrick.

President F. S. Hickok, of the association, has issued the following statement to the electrical public, on the subject:

The necessity for a standard system of electrical diagrams was first brought to the notice of the Chicago Electrical Association through the reading before that society, on the evening of January 15, 1897, of a paper on "Conventional Diagrams of Electrical Apparatus," written and delivered by Mr. D. W. C. Tanner. His active experience in matters pertaining to electrical patents especially fitted him for presenting such a subject. The discussion by the society at the time and the subsequent favorable criticism in the electrical papers, led the society to take steps toward publishing a series of selected diagrams more complete and comprehensive than any heretofore presented. Accordingly, a committee was appointed, with Mr. Tanner as chairman, and Thos. G. Grier, Kempster B. Miller, and S. G. McMeen (ex-officio), as fellow members. Mr. C. Wiler was subsequently chosen an additional member of that committee to take the place of Mr. Tanner, who, unfortunately, was obliged to resign. Mr. Grier was then appointed chairman, and the work has been pushed to completion. We anticipate that this report will furnish the possessor with a convenient, concise form of expressing his ideas in such a manner that they can hardly fail to be understood by any man having a fair knowledge of electrical principles. The ultimate result will be to make all electrical diagrams clear, and uniform in their representation of circuits and apparatus, and save much time and patience now lost in seeking in printed specifications for explanations of the various instruments shown.

The report of the Association Committee on Standard Diagrams is as follows:

The undersigned, your committee, appointed for the selection and preparation of conventional diagrams or symbols representing the various pieces of electrical apparatus in common use, respectfully submit the following report, together with the sheets of drawings annexed.

The time has arrived when the diagrammatic illustration of electrical apparatus should be reduced to an art. A uniform code should be established containing a diagram for each piece of apparatus, each diagram being at once simple, and so far as possible, suggestive of the particular piece of apparatus which it is designed to represent.

A decided improvement has been made in this direction during the last few years, yet at the present time the system is far from perfect. Its development has suffered through a lack of unity among the various makers of these diagrams.

The electrical divisions in the Patent Office have done more toward the development of this art than any other one agency. Often in a drawing accompanying an application for a patent, when a circle was used to represent a battery, and another circle exactly like it to represent a dynamo and still another, differing in no respect, representing the ground, the drawing was necessarily confusing, and was followed with difficulty, if at all. In such cases it has not been infrequent for the Patent Office to suggest to the inventor or his attorney that he submit a new drawing, using a certain adopted form or diagram to represent his battery and another to represent his dynamo, and so on. In this way, and with the well directed efforts of a number of patent attorneys, a great improvement has been made. These diagrams are to further assist in this direction.

It is well to state that no attempt at originality has been made in their selection. All available sources of information have been drawn from, and it has been the aim of this committee to adopt the best, regardless of whether they had been in common use or not. In deciding upon the diagram for any particular piece of apparatus, the question was considered from several standpoints. Simplicity always carried the greatest weight, and when several diagrams of apparently equal simplicity were to be chosen from, that one was taken which seemed most suggestive of the actual piece of apparatus represented.

The sheets of drawings attached to this report are, for the most part, self explanatory, and we think, need no comment. The representation of a dynamo or motor by a circle with two tangent lines showing the commutator and two brushes has long been in common use. This form of diagram may be used for any direct current machine in drawings where the form of the winding of the machine is either well understood or is not essential in the system to be represented. Similarly, the figure below it may be considered the generic alternator. Where it is necessary to show particularly the kind of a machine, the field coils may be added, as shown in the next three figures, which are so simple that they cannot be misunderstood by one accustomed to read electrical diagrams. The diagrams of the tri-phase dynamos or motors are shown by the characteristic windings of their armatures only. Where there is room for a doubt as to whether one of these diagrams represents a motor or a dynamo a letter M or G, as the case may be, will clearly distinguish them.

The diagram representing the motor generator will, perhaps, be subject to adverse criticism. In its adoption, good perspective is undoubtedly sacrificed for ease in drawing, but who can say that the diagram is not suggestive of what it is intended to represent?

The differentiation of the diagrams for the primary battery and for the storage battery from each other and from the ordinary diagram for a condenser, has been the subject of a good deal of thought. The primary battery diagram is the one in ordinary use. The storage battery diagram differs from it by having the plates connected in multiple, as in practice, and by the drawing of a square around it. This diagram will hardly be taken as representing a condenser, for the reason that the lines representing the plates of the battery are made thicker than those connecting the plates to the battery terminals.

The reason for not representing the ordinary hand magneto generator and the constantly driven generator by the same diagram, is that a need actually exists for a distinction between them. This is especially so in diagrams of telephone exchange systems where it is often difficult to distinguish between the hand generators at the subscribers' stations and the power generators at the central office.

The electrical measuring instruments need no comment, we think, owing to their extreme simplicity and the unmistakable evidence which they bear to their identity.

In the matter of single and double circuit breakers, many forms of diagrams were considered, each of which would probably have their advantages in certain places. This brings out well the fact that these diagrams must be taken merely as a guide, and not as a rigid code which must be absolutely followed. For instance, if it were essential that the circuit breaker should have an operating coil in each of the line wires, then it must be left to the designer or illustrator to make his own diagram for illustrating the particular case in hand.

On the simple telephone diagrams, but little comment is needed. It would be well if all would adopt the form of transmitter shown, from the fact that its construction is so extremely simple.

The listening and ringing key for telephone switchboards is a simple representation of one of these pieces of apparatus in common use. The remarks made concerning the cut-outs will apply with equal force to these.

Two diagrams for polarized bells have been shown. The one on the right hand side is preferable where its meaning cannot be mistaken. The almost universal adoption of this form of diagram has led this committee to show it here, although unless one is familiar with polarized bells in telephone work it must be said that it is not at all suggestive. In cases where it is thought best to be extremely explicit, or where the immediate context of the diagram does not suggest the use of a polarized bell, the diagram on the left is to be preferred.

The diagram for a polarized relay is, we believe, given here for the first time. By changing the plus and minus signs from one side of the armature to the other, it may be indicated that the relay will close on a minus current and open on a plus current, or vice versa. This is a feature which will be found at times very convenient.

The distinction between the ordinary resistance and inductive

resistance is both simple and suggestive, the presence of the core inside of the coil conveying to the mind the presence of a certain amount of self induction.

The use of two parallel zigzag lines for induction coils or transformers, lends itself readily to the distinction between the primary and secondary, between the step up and step down transformers, and, moreover, its construction is of such a simple nature, that it was chosen without hesitation by this committee from among dozens of other good diagrams for representing the same apparatus.

In the telegraph sounder the magnet coil has been represented in outline. In this connection it may be said that where it is not essential to know the nature of the winding or the direction of the convolutions, this same form of magnet might be adopted in any of the relays or annunciators used elsewhere in these diagrams.

The selection of a symbol for "a ground" which might be universally accepted is apparent. This custom of some artists of placing palm trees and grass, or the drawing of miniature landscapes surrounding their ground wire may add somewhat to the artistic effect, but certainly nothing to the clearness or merit of their work.

In conclusion it may be said that it is believed that where any particular piece of apparatus is to be presented for which no specific diagram is here found, it will be an easy matter for the person desiring such diagram to make it from the elements here shown.

The effort of your committee has been to group acceptable conventional diagrams in a convenient form, and in carrying out the instructions of the Chicago Electrical Association, we bring to a focus a matter which has been under discussion for several years.

By the official adoption of these diagrams by a recognized body of electrical men, a standard of uniformity is presented to the public. The committee realizes that this list is not complete, but hopes that it will be a nucleus of a uniform symbolic language among electricians.

From time to time, as suggestions may be offered, suitable additions can easily be made to our present selections. Respectfully submitted, Thos. G. Grier, Kempster B. Miller, C. Wiler, Committee.

Aluminum as a Rival of Copper and Brass for Electrical Conductors.

BY ALFRED E. HUNT, S. B.

(President of the Pittsburg Reduction Co.)

COPPER has been used for electrical conductors very largely in the past due to its comparatively high electrical conductivity, power of withstanding corrosion, ease of soldering and brazing, malleability, tensile strength and ductility. The exceptions in the past have been in telegraph wires of soft wrought iron and the brass, and any steel used in the parts of electrical machinery.

Aluminum has already been used successfully for these purposes and this article is written to call attention to its comparative merits as an electrical conductor.

The following facts regarding the metals, copper and aluminum, in bars, rods, and wire suitable for electrical conductors, need first to be considered:

Copper has a specific gravity of 8.93 (Authority—Association of Copper Manufacturers of the United States, 1893); an electrical conductivity, when pure and soft annealed reckoned at 100 in the Matthiessen Scale, but as ordinarily used in electrical conductors of about 98—97.61 (Authority—Prof. W. C. Roberts-Austen); a tensile strength of from 16,500 pounds per square inch in soft annealed pure copper (Authority—Carnegie's Hand Book) to 65,000 pounds per square inch in hard-drawn bars; and a selling price of about fourteen cents per pound in the United States, and an equivalent selling price of 130 marks per 100 kilograms in Germany, for wire, bars, and rods such as are used for electrical conductors.

Aluminum has a specific gravity of 2.68; an electrical conductivity (Commercially pure metal) of 63.00 (Authorities—Chas. F. Scott, of the Westinghouse Electric Company, and Prof. Jos. W. Richards, of Lehigh University); a tensile strength in pure soft wire of 26,000 pounds per square inch, and in hard-drawn rods or wire of 40,000 pounds per square inch.

Special Selling Price: The firm of Aron Hirsch & Son, of Halberstadt, Germany, are ready to sell aluminum conductors in the form of rods, bars, plates, and wire drawn to 2½ millimeters in diameter, at the special low rate of 280 marks per hundred kilograms, for large quantities of metal, and similarly The Pittsburg Reduction Company will sell rods, bars, plates, and wire drawn to No. 12 Brown & Sharpe gauge (eight hundredths of an inch diameter), in large special orders for electrical conductors, at the rate of twenty-nine cents per pound at their works in the United States.

These prices are special rates, below the regular prices for aluminum which these concerns have decided to make for electrical conductors alone, in order to favor the introduction of aluminum for this purpose and to overcome the handicap which aluminum has occasioned by its lower electrical conductivity than copper, in the matter of special low relative prices.

From these facts it is evident that:

1. Any given volume of copper is 8.93/2.68 or 3.332 times heavier than an equal volume of aluminum.

2. The equivalent price of fourteen cents per pound for copper for any length of any equivalent section of aluminum wire or bar, would be 14 cents times the factor 3.332, or 46.65 cents per pound. That is, one thousand feet of wire of, say, one-tenth inch diameter, would cost equally as much if bought of copper at 14 cents per pound, or aluminum at 46.65 cents per pound. Aluminum therefore sold at 29 cents per pound is only about 62 per cent. of the cost of copper at 14 cents per pound section for section.

3. Reckoning the copper conductor to have its maximum of 100 per cent. conductivity, and the aluminum to have a conductivity of 63 per cent. (which The Pittsburg Reduction Company are ready to guarantee for their special pure aluminum metal for electrical conductors), then for an equivalent electrical conductivity a given section of copper that can be placed at 100 should be increased in area in round numbers to 160 to give an equal conductivity.

4. Due to their relative specific gravities, the weight of the given equal length of the aluminum conductor with 160 sectional area will be only forty-eight per cent. of the weight of the copper conductor with sectional area of 100 having the same electrical conductivity.

$100 \times 8.93 = 893$, weight of the copper.
$160 \times 2.68 = 428.8$, weight of the aluminum.
$428.8/893 = 48$ per cent.

5. As to their relative cost for electrical conductors of equal conductivity, aluminum at twenty-nine cents per pound is the most economical conductor as compared with copper at fourteen cents per pound.

Taking as an illustration, an aluminum conductor to replace a copper wire of No. 10 B. & S. gauge (about one-tenth of an inch diameter), the aluminum wire of equal, in fact somewhat superior, electrical conductivity would be of No. 8 B. & S. gauge (slightly over one-eighth of an inch diameter).

The weight of a mile of No. 10 copper wire is 162.32 pounds; and its cost at 14 cents per pound would be equal to $22.72.

The weight of a mile of No. 8 aluminum wire would be 79.46 pounds and at 29 cents per pound would cost $23.04.

Forty-eight per cent. of the weight of the No. 10 copper wire, which will give equal electrical conductivity in aluminum wire, would only weigh 77.91 pounds; so that more accurately, $22.59 would be the cost of a mile of aluminum wire at 29 cents per pound to replace a mile of No. 10 copper wire at 14 cents per pound, costing $22.72.

6. The Continental requirements in tensile strength for soft copper wire, rods, and bars used as electrical conductors is 22 kilograms per square millimeter; the English requirement being similarly fourteen tons per square inch: and our American requirement is about its equivalent of 32,000 pounds per square inch.

Aluminum wire, rods, and bars will be furnished of 63 per cent. electrical conductivity, which will have an equal tensile strength per unit of area with the copper, and therefore with the electrical conductivity equivalent of 48 per cent. of the weight of the copper and sectional area of 160 against the area of the copper section 100, the tensile strength of the aluminum conductors will be as 100 for the copper is to 160 for the aluminum. This would mean if a square inch of copper conductor was used of, say, 32,000 pounds per square inch tensile strength, the equal conductivity area of 1.6 inches of aluminum would have a tensile strength of 51,200 pounds.

It has been already determined that with aerial lines, the snow and ice load is practically as heavy on lengths of small wire as

upon larger sections, so that no objection upon this score can probably be found to the use of the larger sections of aluminum wire.

Both on account of having only 48 per cent. of the weight and on account of having about 60 per cent. more strength, the aluminum conductor could be used in much longer spans between supports, and the number of expensive poles and insulators can be materially diminished. Properly drawn aluminum wire is as tough and will stand bending as severely without breaking as soft copper wire. The toughness of aluminum wire is, however, greatly modified by the care and skill used in manufacture. If it is drawn too severely through the dies or is not well annealed at the proper intervals in the drawing operation, it is finished much more brittle than when properly manipulated.

Hard-drawn copper wire, especially that in the smaller sections drawn through diamond dies, is furnished with a tensile strength of 65,000 pounds per square inch. What the maximum tensile strength of the best pure hard-drawn aluminum will reach under similar favorable conditions for developing the maximum tensile results, has not yet been determined, but from experiments already made it can quite surely be predicted that at least 50,000 pounds per square inch can be obtained, and perhaps even higher strength still.

Aluminum hardened with a few per cent. of alloying ingredients can be furnished in wire with a tensile strength far in excess of what can be obtained in pure aluminum. Experiments are now being made by The Pittsburg Reduction Company to determine just what alloy will furnish the maximum tensile strength, together with maximum electrical conductivity. From results already obtained, it can surely be predicted that an alloy of aluminum can be furnished which drawn into wire will have a tensile strength of at least 65,000 pounds per square inch and electrical conductivity of more than 50 in the Matthiessen scale. This material will rival hard-drawn copper wire and the silicon-bronze materials which are now in use, where maximum tensile strength together with good electrical conductivity are required.

The power of withstanding corrosion is greatly in favor of aluminum as an electrical conductor over copper. Copper does not change in dry air, but in moist air it becomes covered with a green layer of basic carbonate of copper, which itself has a corroding action and does not coat and protect the underlying copper from further corrosion. Ammonia in contact with copper absorbs oxygen and the copper dissolved in consequence of the formation of a soluble cupric-oxide and ammonia. This action is especially a source of trouble where copper wire is used in connecting rail joints in the tracks of electrical railroads where the ground is often subjected to ammoniacal solutions.

Aluminum similarly is not acted upon in dry air and the corrosion in moist air is of the oxide of aluminum, alumina, a harmless salt which forms an impenetrable coating on the metal and protects it from further corrosion to a considerable extent. Ammonia solutions act on aluminum only upon the surface, attacking it and leaving behind a more resisting surface coating of a brown color containing silicon, which resists corrosion from dilute mineral acids and dilute solutions of organic acids as well as moist and dry air. Subject to sulphur gases such as locomotive flue gases, aluminum withstands corrosion better than copper.

If kept free from galvanic action with any other metals electro-negative to itself, aluminum is far less easily corroded than copper.

The difficulty of soldering or brazing aluminum is the chief drawback to its use as an electrical conductor. Aluminum can be soldered strongly, but it is a more difficult and slow operation at best as compared with copper, and there is much more rapid weakening of the soldered joint due to galvanic action between aluminum and the metals of the solder than with the less electro-positive metal, copper.

In many places the aluminum can be first coated with copper and the soldering or brazing operation made on the copper surfaces thus formed.

Several forms of joints have been successfully used to avoid the necessity of soldering; the best forms being to use thin aluminum sheets to wrap the joints and to twist or otherwise bind with the aluminum bars or wires to be joined. These wrapped and twisted joints with aluminum sheets can be left smooth on the outside when desired, can be made much stronger than the body of the conductors, and are really a more serviceable job than soldered or brazed work in many cases with copper. One very practical way of making joints of aluminum wire is to roll the thin aluminum sheet of about six inches width into two cylinders from opposite edges of the sheet. These double cylinders are very cheaply made on mandrels in a lathe. The ends of the wires to be joined are inserted in these cylinders from opposite ends and both the wire and sheet twisted with pliers until a firm joint is secured, much stronger than the body of the wire. The joint can readily be made impervious to the air and moisture.

The C. McIntire Company, of Newark, N. J., have a patented joint which is made very much along the lines of this joint. Information regarding their patented form of joint can be obtained by correspondence with them as above. Also The American Electric Fuse Company, Chicago, Ill., make a very satisfactory joint.

Another disadvantage which handicaps aluminum in special uses for electrical conductors will be where the material has to be insulated that the cost of insulation will be approximately one-third greater for the larger section required in aluminum over the cost for the smaller section of copper required for the given conductors; and where aluminum is to economically compete for insulated conductors, the price of the aluminum will have to be further reduced to meet this contingency.

Aluminum is soon to be placed in an extensive line of conductors where this added extra cost of insulation will be determined by actual fabrication; The Pittsburg Reduction Company in this particular case agreeing to pay the added costs, in order that actual experience may be gained as to their relative amounts.

There are certain places where aluminum will be at a disadvantage over the smaller section of equal conductivity of copper, in ducts or conduits where space is a considerable item. In such cases, the use of aluminum would necessarily be prevented.

An ample field for the employment of aluminum for some time to come, however, seems open at the present time for bare transmission lines, especially for high-potential long-distance work and for long-distance telephone lines and for rapid transmission telegraph lines.

Aluminum next to gold is the most malleable of all the metals and is much more malleable than copper.

Aluminum in ductility stands next to copper and is easily drawn into all sections that are furnished in copper for electrical conductors.

Aluminum can be furnished fully as uniform in its composition as copper.

The metallurgy of copper is comparatively complicated, owing to the difficulty of converting its ores into the oxide free from impurities. In most of the copper ores used, sulphur, lead, and iron are contained as well as small quantities of other elements, as arsenic and antimony. All of these elements in metallic copper very materially lower its electrical conductivity. The native pure copper of the Lake Superior region enjoys the preference, due to its uniformity and freedom from impurities, for many purposes, but for electrical conductors the electrolytic copper is most used.

Aluminum can now be furnished rivaling for electrical conductors at least 99.50 per cent. pure, it is granted not as yet in purity of composition the best electrolytic copper used for the purpose of electrical conductors. When as pure a metal is obtainable undoubtedly it will more nearly rival copper in electrical conductivity section for section.

Aluminum has been already in successful operation as an electrical conductor for some time. The first use in a large way was with the conductors for the electric current at the Niagara Falls Works of the Pittsburg Reduction Company, where it has been used since the year 1895; the currents were of several thousand horse-power each and of very large volume and comparatively low voltage. Both in conducting power, freedom from heating effects, power of withstanding corrosion, ease of making, wear, and efficiency of joints, the aluminum conductors have given better results than copper used for the same purpose.

In the Chicago Stock Yards, a mile of aluminum wire of No. 11 gauge has now been in use for some time, upon a telephone line that has been badly corroded out in copper wire, due to its being frequently subjected to sulphur gases from passing locomotives. The aluminum line is giving good satisfaction and is withstanding corrosion much better than did the original copper wire subjected to the same influence.

If the theory be true that the passage of high voltage alter-

nating currents of great frequency is largely upon or near the surface of the conductors only or mainly, then the larger section of the proposed aluminum conductors will make them especially adaptable for such currents.

On telephone lines, it has already been determined that as good sound transmission is obtained, with aluminum of equal section as with copper, in ordinary lengths of less than ten miles of wire. No comparative results, however, have as yet been determined on long distance telephone transmission; but the evidence would seem to point that a much less section than 160 of aluminum to 100 of copper will give equally good results.

Aluminum is now being used to replace brass very considerably in the arts, as it is sold in the open market at rates which make it ten per cent. cheaper, section for section, than brass.

For electrical purposes, the metal can be advantageously used to replace brass in a good many ways. Commercially pure aluminum as furnished to-day contains less iron than does commercial brass, and is therefore more non-magnetic than brass.

The electrical conductivity of aluminum is far superior, section for section, to brass. Almost every electrical apparatus of present construction in which an iron core—usually a laminated iron core—is used, in motors, generators, or transforming machinery, has spaces for ventilation, and the spacing is made by the means of drawn bars, flat rods or angles or tee shape pieces. Brass has been almost invariably used for this purpose in the past—probably on account of its non-magnetic properties as compared with iron or steel. Drawn aluminum sections can be furnished at a price which is ten per cent. cheaper than brass, section for section; and on account of the lightness of aluminum, it can be advantageously used.

Where a low electrical conductivity is desirable, as in parts that are moved in a magnetic field, to prevent the occurrence of eddy-currents, aluminum can be alloyed with zinc and other metals that will lower its electrical conductivity to the desired point.

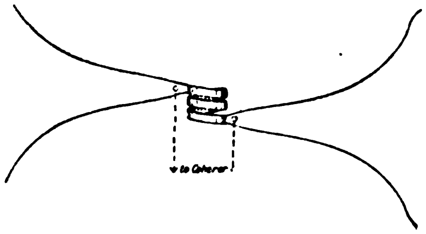
A Doctor's Telephone Lines.

Discussing a bill to tax telephone lines, Mr. Dougherty said recently in the Illinois Legislature: "Over here in Hancock County there is a wealthy doctor who has been building telephone lines. He's gradually extended them until he now has quite a system. Oh, yes, it's a great convenience, but nobody on his lines dares to get sick unless he or she employs this particular doctor. He won't allow any other doctor in the county to be called up through his telephone system."

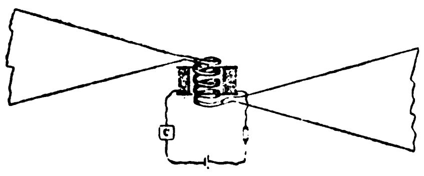
TELEPHONY AND TELEGRAPHY

Prof. Lodge on Electric Signalling Without Connecting Wires.

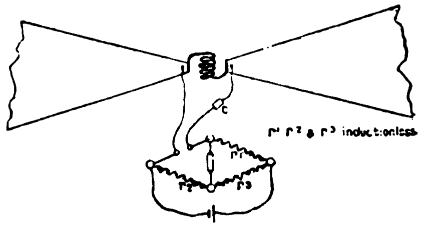
AT a meeting of the Physical Society, held in, London, January 21, 1898, Professor Oliver J. Lodge gave the following interesting communication concerning his work on "Electric Signalling Without Connecting Wires." The illustrations given herewith were made from sketches sent to "The Electrical Engineer," London, by Dr. Oliver Lodge, and are not referred to in the text of the official report.



A SYNTONISED RECEIVER.

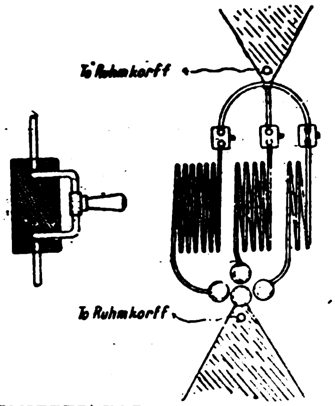


Sketch showing a mode of stimulating coherer by means of currents induced in an outer coil with the simplest connections to coherer.

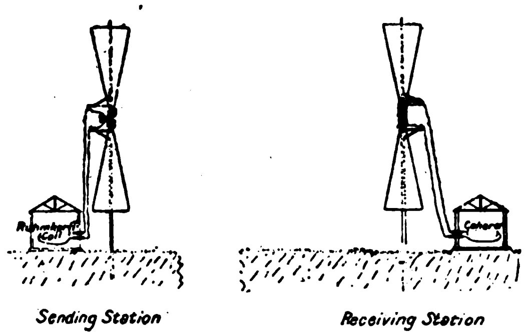


WHEATSTONE BRIDGE CONNECTIONS.

From the nature of the oscillatory disturbances emanating from any of the customary forms of Hertz vibrator, syntony has hitherto been only very partially available as a means for discriminating between receivers. There is, in fact, so rapid a decrease in the amplitude of the vibrations that almost any receiver can respond to some extent. Discrimination by syntony is possible with magnetic systems of space telegraphy where the magnetic energy much exceeds the electric—i. e., as between two separated inductive coils—and by the use of such coils, appropriately applied, the author has been able to attain fair syntony even with true Hertz waves—i.e., he has constructed spark-



EMITTER FOR THREE DIFFERENT RECEIVING STATIONS.
(The connections are plugged up according to station required.)

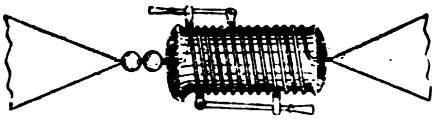


A PAIR OF LONG-DISTANCE SIGNALING STATIONS WITH SYNTONISED EMITTER AND RECEIVER.
(The coils connecting the capacity areas are diagramatically shown.)

A LONG-DISTANCE SENDING AND RECEIVING STATION.
(The insulated metal roof is used as the capacity area, with all its parts well connected up to discharging rod.)

gap oscillators, with sufficient persistence of vibration, and syntonized resonators. The "coherer" principle can be applied to either a purely magnetic or to the Hertzian system. It was first used by Prof. Lodge in devising lightning guards, and afterwards in his magnetic system of telegraphy by inductive circuits, each in series with a Leyden jar, a pair of knobs in near contact, or other overflow gap, being provided in the receiving apparatus. This was the first meaning of a "coherer" in the electrical sense as used by Prof. Lodge: it referred to a single contact between two metal knobs. The term has since been extended by others to the filings tube of M. Branly, and some confusion has arisen, for M. Branly does not consider that simple coherence and break explain fully the behavior of his instrument. Prof. Lodge is disposed to agree, for he finds that the resistance of almost any form of coherer varies in rough proportion to the received impulses, and that there are other peculiarities (to be mentioned later); he is therefore inclined to think that the action cannot, after all, be entirely explained as due to mere "welding," but

that there is something more to be learnt about it. The sensitiveness of a coherer depends upon the number of loose contacts; it is a maximum for a single contact—i. e., for a needle point lightly touching a steel spring. With this sensitive coherer, hardly any "tapping back" is required for decoherence, but it wants delicate treatment when properly adjusted, and the greatest current through it should not approach a milliampere. On the other hand, a Branly tube rather improves under rough treatment. In such a tube the author prefers to use iron filings in the best possible vacuum; brass, too, is very good, but rather less easy to manage. Aluminum is thoroughly bad, and gold, for an opposite reason, will not work—its surface is too clean. Points, or small surfaces for making contact with the filings, are better than large surfaces. The usual method of connecting the coherer across the gap of an ordinary Hertz receiver, in parallel with the telegraph instrument and battery, has the unavoidable objection that it shunts away part of the received oscillations. With the syntonic receiver of Prof. Lodge, which contains no gap but a closed wire coil instead, the difficulty no longer exists, for the coherer can now be in series with the detecting instrument, and in so far as these obstruct the oscillations they may be shunted out in various ways, as the author describes. The main feature of his new syntonized vibrators is this self-inductance coil, whose function it is to prolong the duration of the oscillations, and thereby to render syntony possible. Although such a coil acts disadvantageously in so far as it possesses resistance, the resistance does not increase so fast as the self-induction. The coil should consist of thick copper of highest conductivity, and it should have maximum inductance for given resistance. For similar reasons the capacity areas should also be of highest conductivity; their dimensions should increase outwards from the spark-gap, as triangles. The receiver must



A METHOD OF TUNING A RECEIVER BY MEANS OF A HEDGEHOG CHOKING COIL.

have no gap; it should be accurately bridged over when a transmitter is used as receiver. The limit of speed of response depends upon the telegraphic instrument. Dr. Muirhead adapted a siphon recorder to the purpose, because it is one of the quickest responders. He arranged it so that it could be used with intermittent currents direct. Under these intermittent impulses the siphon trembles, and instead of the ordinary siphon signals the slip is marked with dots and dashes. Constant mechanical tremor is usually employed by decoherence, but the author finds that decoherence can be brought about by electrical means, without any mechanical tremor, by connecting the coherer momentarily to a circuit less effective as a collector than that of the proper capacity areas of the syntonized receiver. The battery and galvanometer detector circuit may be used for this purpose; the coherer being momentarily connected to it, and while so connected, letting it experience an impulse from a distance. Prof. Lodge has designed a revolving commutator, by means of which the coherer can be rapidly changed over from the resonating circuit to the instrument circuit, and finally to the "tapping-back" apparatus. A coherer is more sensitive when thus isolated and exposed to the full influence of the received oscillations. The subsequent detection of the effect by altered connections is very convenient for laboratory measurements. A diagram of a series of plotted measurements showed that the resistance of an undisturbed filings tube is approximately a direct function of the intensity of the received stimulus, whether successive stimuli increased or decreased in strength. This electrical process of "tapping back" is to be depended upon, but the process long continued fatigues the tube until a mechanical shake is employed to restore it. Large-size apparatus made by Dr. Muirhead for actual distant syntonic work was exhibited, and means were shown for protecting and isolating the coherer when its receiving areas were being used as emitters; also a switch used for changing at one moment all the connections from "sending" to "receiving."

The discussion which followed was participated in by Prof. Threlfall, Mr. Rutherford, Mr. Campbell-Swinton, Prof. Herschel and Dr. S. P. Thompson, the last of whom exhibited a Tesla oscillator. This apparatus Prof. Lodge said would work quite well with as low a voltage as 10 volts and in answer to a question by Prof. Herschel whether the Tesla oscillator was suitable for work with Röntgen rays, Dr. Thompson congratulated Mr. Tesla upon the perfect working and compactness of his invention, and stated that the present form was not suited for Röntgen ray experiments with the ordinary focussing tubes, but Mr. Tesla had designed a special tube which gave most excellent results with the coil.

Drug Store Telephony in Detroit.

The Michigan Telephone Company has inaugurated a new plan of pay stations, or, rather, an extension of the old system, as many people who have been in the habit of using drug store telephones have found out. The scheme is this: A druggist, for instance, is offered free telephone service for himself, if he will allow the company to place in his store a telephone with a nickel-in-the-slot attachment, so that all transient users of the telephone will be compelled to pay for the service. The drug store can be called up by any of its customers, and there will be no charge, but the druggist himself is limited to free service with wholesale houses, the hospitals, police and health boards, and all physicians. Many druggists have already installed the new system and report that so far it has worked satisfactorily.

A French Cable to Honolulu.

A special dispatch from San Francisco says: Advices received from Honolulu by the steamer Marchesa state that the French cruiser Duguay Trouin arrived there February 3, her commander bearing a letter from the French Governor of Tahiti, informing the Hawaiian Government that the French cable from Tahiti to Honolulu was to be laid at once, and in future the Messageries line would call at Honolulu. This letter caused the utmost consternation in government circles, and a dispatch was sent at once to Washington asking for instruction and advice.

Opposition to Bell Telephone.

William L. Holmes, who is one of the organizers of the Union Telephone Company, just incorporated in Maine with a capital of $10,000,000, and who is prominently associated with the Detroit Telephone Company, says: "The new concern is only a forerunner of an opposition to the Bell telephone monopoly, more gigantic than anything ever before attempted in that line."

OBITUARY

J. H. Rhotehamel.

It is with extreme regret that we note the death of Mr. J. H. Rhotehamel, president of the Columbia Incandescent Lamp Company, of St. Louis. At the beginning of the month he went from St. Louis to Hot Springs, Ark., for rest and treatment, taking his family with him. After commencing his regimen, he became seriously ill, but no alarm was felt as to results. Other doctors were called in later, and his family were advised to return home with him. He reached St. Louis on the Wednesday, and on Thursday died of congestion of the brain.

Mr. Rothehamel was a fine type of the modern, progressive business men of St. Louis and of the younger commercial talent enlisted by the electrical industry. He made himself very prominent by his fight in behalf of the Goebel lamp claims, in which he believed firmly and which he supported with a generous array of legal talent. As to the Columbia lamp, he pushed that to a front place by his skill in factory management; and he won for the Columbia products a high esteem everywhere. Of late he had been an active and loyal member of the lamp "combination" recognizing patents and sustaining prices. His personality was agreeable, and he made himself generally liked, not least by those whom he had to oppose.

The funeral services took place on February 19. We beg to add our own regrets to those of all who knew Mr. Rhotehamel, and to offer the family our condolence.

Lord Sackville Arthur Cecil.

Lord Sackville Arthur Cecil (half brother to the Marquis of Salisbury) died recently at Holwood, Kent, England, after an illness of several weeks. In early life Lord Cecil showed signs of scientific tastes and after his graduation from Cambridge was engaged in the carriage department of the Great Northern Railway. He subsequently joined the traffic department of the Great Eastern Railway, and showed a lively appreciation of the details of the working of a great railway system. From 1878 to 1880 he held the post of assistant general manager of the line. In 1880 he was appointed general manager of the Metropolitan District Railway, and continued in that post for five years.

He then became associated with submarine telegraphy, and at the time of his death was a director of the Eastern, the Brazilian Submarine, and the Pacific and European Telegraph Companies, and of the Globe Telegraph and Trust Company.

He was a man of the simplest habits, of unvarying courtesy to all, of the keenest intelligence, doing all he undertook with the utmost thoroughness and conscientiousness. He will be greatly missed and widely regretted.

Effect of Roentgen Rays on Vegetable Life.

Experiments on the action of Röntgen rays on vegetable life have hitherto mostly led to negative results; but Signor G. Tolomei, writing in the "Atti dei Lincei," is led to the conclusion that their action is identical with that of light. On exposing to the action of Röntgen rays branches of Elodea canadensis immersed in water charged with carbonic anhydride, evolution of bubbles took place as in the presence of sunshine or electric or magnesium light. The same similarity was observed in the effects on the lower vegetable forms, both Röntgen rays and light causing retardation in the absorption of oxygen by Mycoderma aceti, and in the evolution of carbonic anhydride by Saccharomyces. Again, in their action on Bacillus anthracis the Röntgen rays behave in the same way as sunshine, but in a minor degree; when a gelatine film was exposed for twenty-four hours to the radiations from a Crookes' tube, with the interposition of a zinc screen having an X-shaped aperture, the letter appeared transparent on an opaque background. That the action was due to destruction of the germs, and not to the generation of any toxic quality in the agar, was proved thus: when a sterilized film was partially exposed to the rays, and subsequently brought into contact with a stratum of dried spores, the spores began to germinate all over the film; but when the stratum of spores was exposed to the rays, the screen with the letter X being interposed, and the film subsequently brought into contact with them, only those spores which had been protected from the Röntgen rays developed, and the letter X was distinctly seen. Signor Tolomei attributes the previous failure to obtain such effects to the short duration of the exposures.

PERSONAL

MR. FRANK J. SPRAGUE, formerly a lieutenant in the U. S. Navy, has tendered his services to the Navy Department, asking to be assigned to active duty should the occasion arise.

MR. F. VON HEFNER-ALTENECK has been given an honorary doctorate by the University of Munich, on account of his services to the theory of electricity and to the modern development of electrotechnics. The new doctor is well known as the inventor of many improvements in the design and construction of dynamos in the early days of electric lighting. He also invented the Hefner or amylacetate lamp, which is now charge a case full of beautiful silverware.

MR. W. J. MARTIN, retiring manager of the Western Union Company's main office at San Francisco, has received from the employees of the operating and other departments under his charge a case full of beautiful silverware.

MR. C. F. MUNDER, treasurer and general manager of the Davis Electrical Works, Springfield, Mass., sailed on the St. Paul on Wednesday, the 16th, for London and Paris. Mr. Munder contemplates establishing agencies abroad for the sale of his company's product.

A Brilliant Telegraph Tournament for the Electrical Exhibition.

WE have received from the Exhibition management the subjoined excellent article from the "Telegraph Age," giving some details and data as to the great telegraph tournament that will be held at the Madison Square Garden. It is said that the tournament will take place during the second week of May:

As already announced, the New York Electrical Society, during the month of May, will give, under its auspices, an electrical exhibition in Madison Square Garden, New York. In connection therewith, an auxiliary and educational committee has been formed to take general charge of exhibition matters other than commercial, and it has been decided that one or more evenings during the exhibition shall be set apart for a telegraph tournament, and we take great pleasure in advising the "crack" senders and receivers of America to tune up their keys and sounders and get on their best gait, for there will certainly be a "hot time" in Madison Square Garden some time during the month mentioned.

It goes without saying that this will be the greatest telegraph tournament ever held in the world. The committee has secured the services of Mr. Fred Catlin, who is the most competent gentleman to successfully conduct an affair of this magnitude. Mr. Catlin is justly termed "the father of telegraph tournaments," for, with one exception, he has managed every telegraphic contest which has been held in New York since 1866, when Mr. Pat Burns, of Boston, won the gold key, including the Bunnell key contest, in the Western Union Building in 1884, which was won by Mr. W. L. Waugh; the Victor key contest, in the United Press rooms in 1885, won by Mr. J. W. Roloson, and the great national fast-sending tournament at Hardman Hall in 1890.

These affairs were not conceived or carried out by Mr. Catlin with a view to pecuniary gain, but through his interest in the matter of bringing the art of telegraphic manipulation up to its highest point. We have heard him say he would prefer hearing the music of a Roloson's, Gibson's, Kihm's, or Frank Catlin's transmission to listening to the grandest of operas, and in this respect he is not unlike many whom we have met.

Mr. James D. Reid, the "father of the telegraph" and well-known to every operator the world over, has consented to act as chairman of the board of judges. Mr. Reid's appearance on such an occasion as this will be hailed with positive delight by the fraternity at large, and no doubt his presence will encourage operators from all sections of the country to visit New York to capture some of the numerous prizes.

Mr. J. B. Taltavall, a member of the auxiliary and educational committee, will also assist in looking after the interests of the telegraph boys.

In conversation with Mr. Fred Catlin a few days ago, he remarked that he also was determined that the telegraph tournament should be a success in every particular and that it shall surpass any previous affair of its kind. The management will spare no efforts to make this feature of the exhibition a most attractive and successful one. The prizes will be liberal and the contests numerous, and there will be ample opportunity for the young talent which has come into the field since the last tournament of five years ago to show of what stuff it is composed. "It is my opinion," said Mr. Catlin, "that the records will be smashed by more than one.

"The exact dates of the contests have not yet been determined. If it is found that one afternoon and evening are not sufficient

time for running off the various classes, more time will be allotted.

"Handsome medals or badges will be awarded to the winners, to which will be added liberal cash prizes.

"The prevailing opinion, in which I concur, is that the same matter should be used in every telegraphic contest for the purpose of comparison. It is just as necessary and important in this work as it is that the mile race track should measure exactly 5,280 feet.

"At the tournament of 1893 the top records were:

	Minutes.	Words.	
Kihm	5	248	perfect.
Catlin	5	248	"
Gibson	5	246	2 errors.
Mecredy	5	249	14 "
White	5	248	10 "

"The matter used in the contest of '93 was entirely different from that used in '90, so exact comparisons of work done can not be made. The transmission of Mr. Pollock in the tournament of 1890, while it was the most remarkable ever listened to in a public contest in the matter of speed, would not have been acceptable under the conditions of the contest of 1893, owing to the frequency of imperfect characters. It is possible for a first-class operator to read easily perfect transmission up to a speed of about sixty words per minute, a speed not likely to ever be reached by hand transmission. The value of transmission is lost when it is not rendered clear and accurate, and judges will so render their decisions."

Mr. Catlin will as soon as possible issue a circular for the information of operators desiring to participate in the contests. This circular will contain records of past tournaments, conditions to govern the coming affair, classifications, date of closing of entries, the matter to be used in transmission, and other things which may be suggested as being of interest to the fraternity.

Of course, one of the features of the tournament will be a typewriter receiving contest, which it is expected will be participated in by the friends of every known typewriter on the market.

The most liberal prizes will be awarded to the victors, and we can assure those who wish to participate in this tournament, whether residents of New York, Chicago or San Francisco, that they will be well taken care of and repaid for their trouble if they will visit New York and take part in this greatest of all telegraph contests.

SOCIETY & CLUB NOTES

American Institute of Electrical Engineers.

The 122d meeting of the Institute was held at 12 West Thirty-first street, New York City, on Wednesday, February 23, 1898, at 8 o'clock p. m. A paper was presented by Mr. Charles P. Steinmetz, of Schenectady, N. Y., on the "Single Phase Induction Motor."

Anniversary of the Institution of Junior Engineers.

THE thirteenth anniversary of the Institution of Junior Engineers was held on Saturday, Jan. 29, 1898, at the Westminster Palace Hotel, London.

After the loyal toasts had been honored, Mr. Alexander Siemens gave the toast, "British Railways." He could not, he said, help thinking that the management and development of English railways had a very direct bearing on the question which gave rise to the late engineering dispute.

Prof. Perry proposed the toast of "A Realized Teaching University for London." He said he would have liked to have talked about railways and all that, but he didn't know anything about it. There was one thing he would like to know, however, and that was when were they going to take cycles at a cheap rate.

Prof. S. P. Thompson, in responding, said a great change was coming over the teaching of science. It used to be thought that science could only be learned from books, but now it was coming to be understood that the only way to learn it was by working in the laboratory. Mr. Hiram S. Maxim said only one or two miles per hour more than 60 miles per hour could now be got out of an ordinary locomotive whatever improvements were effected. He thought that if electricity were introduced on any of the lines now in use, they might possibly get up to 100 miles per hour. The finest coal had to be used in express locomotives, but with electricity they could burn coal costing half the price. Electricity had been brought so much into use in the United States that it had lowered the price of horses one-half; in fact, it was said that at one place horses were being killed and potted to send to France.

Mr. Aspinall said he thought Americans worked harder, and turned out more work than Englishmen. The English had very carefully constructed machine tools, but the men did not get half as much work out of them as they might.

Members Elected to the New York Electrical Society.

At the 185th meeting of the New York Electrical Society, February 11, the following members were elected: Prof. Robert Ogden Doremus, Max Loewenthal, James H. Bates, Raymond W. Charles, W. L. Hedenberg, Frank Martin, F. A. Pattison, Geo. C. Hoffman, Thorburn Reid, Robert Lozier, Prof. Sidney H. Short, Geo. Sommer, John J. Swann, Meyer S. Blumberg, Frederick W. Young, Wesley Gray Gilmour, Edwin Adelbert Howe, H. F. Sanville.

ENGINEERS' SOCIETY OF WESTERN PENNSYLVANIA.—At a regular meeting of the society held in its lecture room on Tuesday, Feb. 15, a paper was read by Mr. J. N. Chester on "The Elevated Condenser for Central Condensing Plants" before the Chemical Section; on Thursday, Feb. 17, Mr. J. O. Handy read a paper on "The Municipal Laboratories of Hamburg, Germany." Mr. Reginald A. Fessenden is the secretary of the society, and the society's house is located at 410 Penn avenue, Pittsburg, Pa.

LEGAL NOTES

The Home Telephone Co. of Mobile, Enjoined on the Scribner Patent No. 330,061.

IN the early part of last year suit was brought by the Western Electric Company against the Home Telephone Company, of Mobile, Ala., for infringement of a Scribner patent. The testimony given in the case as well as the points at issue were fully discussed in our issue of July 22, 1897. The patent in suit was that of C. E. Scribner, entitled "Multiple Switchboards," No. 330,061, November 10, 1885. The patent relates to multiple switchboard signals, designed to enable the operators at the different boards to test what lines are in use, while the circuits are so arranged that any two lines may be connected together upon any one of the boards without including in their circuit the resistance of the contact points of the switches.

The complainants alleged that claims 2, 4 and 6 of the patent were infringed. These claims read as follows:

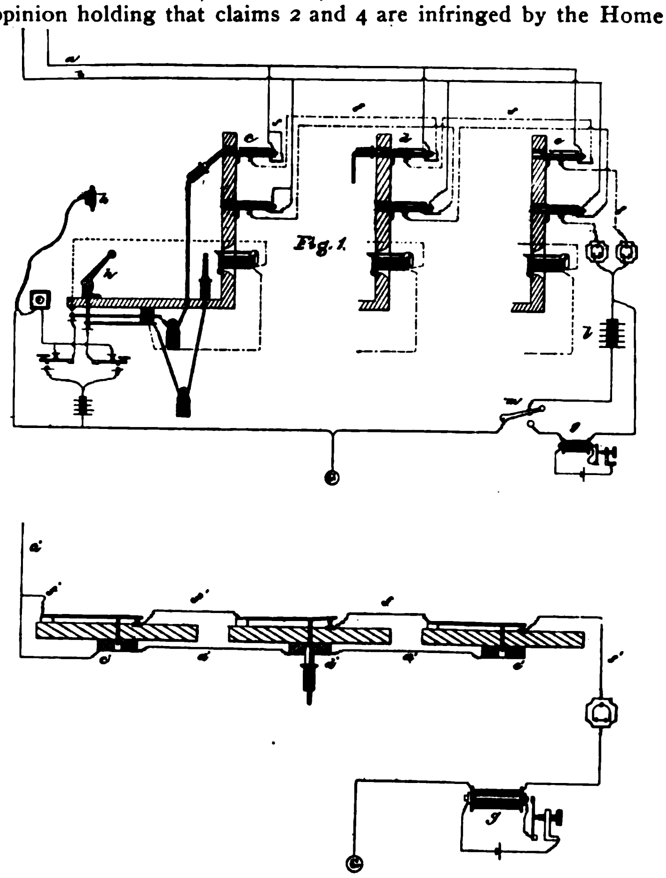
"Claim 2.—At a telephone exchange central office the combination of multiple switchboards with telephone lines, each permanently connected to a metallic portion of its switch upon each board, each telephone line being also connected through the contact points of its switches and to ground, and means whereby the circuit of the branch wire of any given line is opened when a connection is made with the line at any board whereby any two lines may be connected together upon either of the boards without including in their circuits the contact points of either of their switches."

Claim 4.—The combination, with a telephone line provided at each switchboard of a multiple system with a connecting bolt or switch of a portion of said line connected through an annunciator to ground and means for breaking said line when a connection is made with the telephone line at either one of its

bolts or switches substantially as and for the purpose specified."

"Claim 6.—In a multiple switchboard system, a telephone line provided with a spring jack at each switchboard of the system, said spring jacks being provided with insulated metallic frames, and said telephone line being connected directly to each of said insulated frames, and also through an annunciator to ground through the springs and contact points of said spring jacks, whereby a connection may be made direct to the telephone line at any board at the same time the portion of said line containing the annunciator is broken, substantially as set forth."

Judge Toulmin, before whom the case was argued in the U. S. Circuit Court, at Mobile, has handed down an elaborate opinion holding that claims 2 and 4 are infringed by the Home



FIGS. 1 AND 2 OF SCRIBNER'S PATENT NO. 330,061.

Telephone Company, but that claim 6 has not been shown to be infringed.

No decree was issued against Adam Glass and Alfred S. Lyons, officers of the Home Telephone Company, as it was not shown that they had derived any individual profit from the patent sued on.

A decree was entered, accordingly, for an injunction and an accounting of the profits and damages with respect to claims 2 and 4, the injunction not to be operative until 60 days after entry of decree, so as to avoid inconvenience to the public.

A Kentucky Law Forbidding Consolidations.

The Kentucky House has passed a bill to forbid any railroad, telegraph, telephone, bridge, or common carrier company to consolidate its stock, franchises, or property, or to pool its earnings with a parallel or competing line, or to acquire such line. It also forbids any combination between common carriers by which the earnings of the one doing the carrying are to be shared by the other not doing the carrying.

THE SPRAGUE ELECTRIC COMPANY has offered $1,000 reward for information leading to the detection and conviction of the thief who stole certain papers from the desk of vice-president Frank J. Sprague, in the company's offices at the Commercial Cable Building, Broad street. It is said that the papers related to recent railway inventions and calculations.

MR. C. C. LONG writes: "Allow me to express my appreciation of the way in which The Electrical Engineer is being conducted."

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents issued February 8, 1898.

Alarms and Signals:—

AUTOMATIC ELECTRIC FIRE ALARM. W. A. Guthrie, Durham, N. C., 598,508. Filed July 7, 1897. Comprises a push button containing a spring contact normally closed but held open by an extension of easily fusible metal.

TESTING APPARATUS FOR ELECTRIC CIRCUITS. E. and F. W. Heymann, Boston, Mass., 598,517. Filed February 26, 1897. Adapted for telephone or signal systems; details of construction.

ELECTRIC CALL BOX SYSTEM. W. T. Budds, Charleston, S. C., 598,853. Filed August 23, 1897. Provides a single wire open main circuit having a single wire connection with each call box, the circuit being completed through the ground.

Batteries, Primary:—

PRIMARY BATTERY CELL. F. H. Brown, Chicago, Ill., 598,556. Filed December 9, 1895. Comprises a negative element, composed of an agglomerate of black oxid of manganese and plumbago, and having superimposed layer of carbon, sealed with an insulating material, and having a conductor embedded therein, and a positive element.

Conductors, Conduits and Insulators:—

JUNCTION BOX FOR ELECTRIC CONDUCTORS. T. J. Close, Philadelphia, Pa., 598,498. Filed May 26, 1897. Embodies a lid with a series of openings registering with the flange-openings and bolts for openings with locking nuts.

Dynamos and Motors:—

CONSTRUCTION OF DYNAMO ELECTRIC MACHINERY. A Soames, London, Eng., 598,540. Filed December 6, 1897. The bearings for the armature shaft are secured to the frame by castings of type metal.

ALTERNATING CURRENT DYNAMO. W. B. Esson, London, Eng., 598,657. Filed April 21, 1896. Employs an armature core-piece provided with orifices for embedding the coil and formed with additional orifices.

Lamps and Appurtenances:—

ELECTRIC ARC LAMPS. S. I. Crain, Cincinnati, Ohio, 598,697. Filed July 24, 1897. Employs a pair of pivoted arms carrying rollers adapted to engage with the upper carbon near its point of support, and electrical connection between the rollers and the main.

INCANDESCENT ELECTRIC LAMP AND PROCESS OF MAKING SAME. J. C. Fish, Shelby, Ohio, 598,726. Filed August 3, 1897. Embodies a mount composed of a pair of tubes rigidly braced together, a plate fused to the lamp globe and to which the ends of the mount are fused, and through which the leading-in wires contained in the mount project.

Miscellaneous:—

PROCESS OF MANUFACTURING GRAPHITE. H. H. Wing, Buffalo, N. Y., 598,549. Filed December 14, 1896. Consists in passing an electrical current through carbonaceous material, whereby the heat thus produced converts part of the carbon into graphite, and then separating the unconverted carbon from the graphite.

ELECTRIC HEATER. J. F. McElroy, Albany, N. Y., 598,638. Filed March 24, 1894. Adapted for use in drying barrels, casks, etc.

ELECTRIC RADIATOR. J. F. McElroy, Albany, N. Y., 598,639. Filed January 25, 1895. For street railway cars; details of construction.

ELECTRIC HEATER. J. F. McElroy, Albany, N. Y., 598,640. Filed April 6, 1895. Comprises two over-lapping plates adapted to slide relative to each other and provided with insulating edges, means for connecting the plates together, springs arranged between the plates tending to force them apart, and a resistance wire wound around the plates.

MANUFACTURE OF CARBONS. C. L. Saunders, Cleveland, Ohio, 598,646. Filed June 3, 1897. Consists in mingling the carbonaceous material with a binder in liquid form, grinding the mixture while wet and distilling off the volatile elements of the mixture.

BENT ROTATABLE GASTROSCOPE. G. E. Kelling, Dresden, Germany, 598,787. Filed March 20, 1897. Comprises a casing, having a rotatable head section containing an illuminating device.

VELOCIPEDE. G. J. Scott, Philadelphia, Pa., 598,819. Filed May 4, 1897. Employs a series wound dynamo driven from the crank shaft to supply current for a motor geared to one of the driving wheels.

Railways and Appliances:—

TROLLEY HEAD. H. W. Smith, Somerville, Mass., 598,580. Filed June 10, 1897. A trolley head having an annular enlargement having a groove therein, an endless ring closed into the groove so as to enclose the head more than half of the circumference, the remainder of the ring being bent outward to form an eye for the attachment of the trolley rope.

ELECTRIC STREET CAR TROLLEY. J. T. Himmeger, La Rue, Ohio, 598,661. Filed Oct. 20, 1896. Means whereby the pole can be shifted by the motorman without leaving the platform of the car.

ELECTRIC RAILWAY. M. T. A. Kubierschky, Berlin, Germany, 598,-731. Filed March 26, 1897. Employs a controller having contacts for closing the motor circuit with the heating circuit open, and subsequently closing the heater circuit after the motors have attained speed.

Switches, Cut-Outs, Rheostats, Etc.:—

ELECTRIC SWITCH. J. M. Andersen, Boston, Mass., 598,553. Filed Dec. 5, 1896. A cover is provided with a movable portion attached to the movable member of the switch, so that the act of uncovering the uninsulated parts of the switch opens the same.

METHOD OF MANUFACTURING RHEOSTATS, ELECTRIC HEATERS, Etc. H. W. Leonard, New York, 598,568. Filed April 9, 1897. Embodies a number of inseparable resistance steps of practically the same size and design and the ohms of a series of the steps being tapered progressively.

MEANS FOR USE IN OPERATING ELECTRICAL SWITCHES. T. H. Parker, Tettenhall, England, 598,679. Filed Dec. 9, 1897. Consists of a lever and roller escapement adapted to the purpose of operating and locking an electric switch.
AUTOMATIC ELECTRIC SWITCH. F. C. Perkins and J. D. Killip, Buffalo, N. Y., 598,715. Filed Sept. 25, 1897. Details of construction.
SAFETY CUT-OUT FOR ELECTRIC LAMPS. A. N. Lovelace, Knoxville, Tenn., 598,733. Filed June 12, 1897. Designed to be suspended by the hanging cord, together with the lamp.
ELECTRIC TIME SWITCH. G. P. Goodwyn, Arnprior, Canada, 598,864. Filed April 26, 1897. Details of construction.

Telephones:—

COIN CONTROLLED TELEPHONE PAY-STATION. Wm. Gray, Hartford, Conn., 598,610. Filed December 4, 1895. Embodies a sectional toll-box with one part secured in contact with the transmitter base, a signal device rigidly supported on the wall of the toll-box, and a cover containing a money pocket and removably secured to the fixed part of the toll-box.

Classified Digest of U. S. Electrical Patents Issued February 15, 1898.

Alarms and Signals:—

ELECTRICAL ALARM WATER COLUMN. M. L. Bush, Lawrence, Mass., 599,220. Filed June 14, 1897. Comprises a water cylinder containing a float and means at the top and bottom of the cylinder for sounding an alarm with respect to a predetermined height of water to be carried in the steam boiler.

Batteries, Secondary:—

BOX OR CASE FOR SECONDARY BATTERY ELECTRODES. G. W. Harris and R. J. Holland, New York, 598,926. Filed September 3, 1896. Comprises a box of insulating material on the inner side of which are ribs to prevent the plates from buckling.

Conductors, Conduits and Insulators:—

TIP FOR ELECTRIC CONDUCTORS. A. B. Blodgett, Lowell, Mass., 598,972. Filed December 22, 1896. Comprises a conducting core, a non-conducting covering and a conducting needle, having a transverse hole arranged within the covering, and a wire passed through the covering and hole, to retain the needle and wire in place.
UNDERGROUND CONDUIT FOR ELECTRIC WIRES. A. L. Daniels, North East, Pa., 599,292. Filed December 22, 1897. Consists of sections having a metal case, with ends of insulating material of less internal diameter than the case, the ends of adjacent sections being conformed to fit together.

Dynamos and Motors:

DIRECT ACTING OSCILLATING ELECTRIC MOTOR. J. H. Mason, Brooklyn, N. Y., 598,946. Filed March 24, 1897. The oscillating movement of the armature changes the direction of the electric current for alternately swinging the armature a limited distance in both directions.

Electro-Therapeutics:—

ELECTRIC BATTERY FOR MEDICAL PURPOSES. C. W. Moessner, Philadelphia, Pa., 598,948. Filed June 2, 1896. Embodies within a single box the various electrical appliances which are usually required in the practice of medicine and surgery.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. G. R. Lean, Cleveland, Ohio, 598,942. Filed February 20, 1897. Feed mechanism for alternating current arc lamps.
ELECTRIC ARC LAMP. G. R. Lean, Cleveland, Ohio, 598,943. Filed February 20, 1897. Focusing lamp; details of construction.
INCANDESCENT LAMP. J. T. Lister, Cleveland, Ohio, 598,002. Filed October 14, 1896. Means for detachably attaching a cap to the lamp shell and making the necessary electric connections with the lamp socket.
ELECTRIC ARC LAMP. C. N. Black, New Haven, Conn., 599,032. Filed April 20, 1897. Embodies a pivotally-supported armature carrying a plunger and a dash-pot loosely supported from above, in which the plunger works.
ELECTRIC ARC LAMP. C. Tepel, Bennett, Pa., 599,305. Filed March 10, 1897. Feed mechanism.
MAKING FILAMENTS FOR ELECTRIC LIGHTING. D. C. Boss, Boston, Mass., 599,306. Filed August 3, 1891. A process of building up a filament by dipping in the alcoholic solution of iodid of aluminum and then charring the same.

Measurement:—

APPARATUS FOR ELECTRICALLY MEASURING TEMPERATURES. H. L. Callendar, Montreal, Canada, 598,905. Filed July 31, 1896. Comprises a pyrometer employing a galvanometer placed in a battery circuit.
ELECTRIC METER. C. Raab, Kaiserslautern, Germany, 599,046. Filed February 27, 1896. Solenoid meter for alternating currents.
DIRECT CURRENT METER. G. A. Scheeffer, Peoria, Ill., 599,302. Filed May 7, 1896. A direct current meter wherein a registering-train is driven by an armature mounted upon a shaft provided with a damping device.

Miscellaneous:—

FILTERING APPARATUS. C. Palmer and H. G. Brownell, Louisville, Ky., 599,009. Filed January 2, 1897. The water is run through a cell in which iron plates are suspended and through which a current of electricity passes, after which it is filtered through sand.
ENGINE STOP. J. R. and F. P. Reynolds, Hartford, Conn., 598,014. Filed May 29, 1897. Details of construction.
ELECTRIC ELEVATOR. H. Rowntree, Chicago, Ill., 599,015. Filed February 28, 1896. Comprises a main motor, an auxiliary motor, means for controlling the latter, and means actuated by variations in speed of the motors for controlling the main motor.
AUTOMATIC RAILWAY GATE. J. F. Small, Chicago, Ill., 599,019. Filed January 12, 1895. Operated by solenoids.
RAILWAY GATE. J. F. Small, Chicago, Ill., 599,020. Filed March 19, 1895. Similar to above.
TRANSFORMING POTENTIAL ENERGY OF CARBON INTO ELECTRICAL ENERGY. H. Blumenberg, Jr., New York, 599,094. Filed April 7, 1896. The positive element is carbon immersed in molten caustic potash into which steam is injected.
ELECTRIC GAS LIGHTING APPARATUS. W. E. Cram and J. H. L. Clegg, Boston, Mass., 599,121. Filed April 30, 1897. Embodies means to automatically relight the gas if extinguished accidentally.
DEMAGNETIZING DEVICE. H. A. Storrs, Burlington, Vt., 599,304. Filed June 18, 1897. Designed for use in demagnetizing heddles and warp-stop detectors in looms.

Railways and Appliances:—

TROLLEY. C. H. Johnson, Elmhurst, Cal., 598,937. Filed October 24, 1896. Designed for double track roads having a common conductor wire.
TRACK BOND FOR ELECTRIC RAILWAYS. F. T. Mather, Detroit, Mich., 598,947. Filed June 29, 1896. The rail sections are provided with a flanged tread having a continuous groove passing entirely through the flange at the ends of each of the sections, and a continuous electrical conductor lying in the groove and having a loop formed at the junction of each of the rail sections.
INSULATED JOINT FOR RAILROAD RAILS. T. O'Brien, Jr., Philadelphia, Pa., 599,081. Filed June 4, 1897. Comprises a metallic plate having an insulating block seated therein, the plate having a cut-away portion in a wall for the insertion of a suitable implement for removing the block.
ELECTRIC SYSTEM OF PROPULSION. W. M. Brown, Johnstown, Pa., 599,162. Filed May 18, 1897. Consists in the arrangement of the main feeders, sub-feeders, junction boxes, contacts, and safety devices in a conduit system.
ELECTRIC CONTROLLER. F. A. Merrick, Auburndale, Mass., 599,186. Filed May 27, 1897. For railway use. Details of construction.
TROLLEY POLE FOR OVERHEAD ELECTRIC RAILWAYS. J. L. Walker, Louisville, Ky., 599,274. Filed June 18, 1897. Comprises a pole to automatically collapse and fold in the event of the trolley leaving the conductor wire.
TROLLEY ACTUATED SWITCH OPERATING DEVICE FOR ELECTRIC RAILWAYS. L. E. Walkins, Springfield, Mass., 599,307. Filed August 13, 1897. Designed for third-rail systems.

Switches, Cut-Outs, Etc:—

AUTOMATIC CUT-OUT FOR ELECTRICAL CONVERTERS. W. J. Greene, Cedar Rapids, Iowa, 598,922. Filed January 13, 1896. Embodies a controller, a switch closer for the primary circuits, a releaser for the controller-switches, and a connection thereof with the switch closer.
FUSIBLE CUT-OUT. J. Jones, Jr., Brooklyn, N. Y., 598,940. Filed March 12, 1897. The terminals are rigidly connected to the insulating block and the fuse is held in place by springs under pressure of the cover.
CONTROLLER FOR ELECTRIC MOTORS. E. W. G. C. Hoffmann, Charlottenburg, Germany, 598,991. Filed December 29, 1897. Consists in providing in connection with the switching arm an automatically-actuated rheostat adapted normally to cut a predetermined amount of resistance in circuit, but which is maintained in its adjusted position during the time that the switching apparatus is inoperative.

REPORTS OF COMPANIES

New York Edison Co.

The Edison Electric Illuminating Company, of New York, has voted to increase its capital stock by 15 per cent., offering the additional amount to present stockholders at par. Payment is required in three equal installments—on March 10, May 2, and August 2. The new stock does not carry interest or dividends until fully paid. Stockholders may anticipate the full payment receiving 3 per cent. discount until the stock is delivered.

EDISON ELECTRIC ILLUMINATING COMPANY OF NEW YORK shows a gain in net of $23,345, available for dividend purposes, etc., during January.

METROPOLITAN TRACTION COMPANY OF NEW YORK will, it is said, issue $10,000,000 of additional stock, making $40,000,000 in all, and retiring $6,000,000 of debenture gold certificates. The earnings in February show a gross daily increase of about $3,000.

THE STOCK MARKET

Market Steady In Spite of Spanish Troubles.

The disaster which happened last week, when the U. S. man-of-war "Maine" went to the bottom of Havana harbor, by means unknown, had its natural effect on the stock market; and the end may not be yet. But the nerves of the people have remained unshaken, and there is every indication that if war is precipitated it will not be for lack of self control in America.

During the week, 33,053 shares of Western Union were sold, down to 91, losing only 1½ during all the alarm and excitement. Of General Electric, 21,885 shares were sold, from 37½ down to 34½. In Boston American Bell telephone sold down to 265.

TRADE NOTES & NOVELTIES

General Electric Lamp Inspector's Indicating Wattmeter.

THE successful operation of an incandescent lighting system depends largely upon the use of lamps of proper efficiency. To secure the most satisfactory service and highest economy, the efficiency of the lamps should be as high as the fluctuation of voltage on the circuits will permit. The selection of lamps for a particular installation should, therefore, be made with regard to the regulation obtained with the transformers in use. Efficiency is also the true basis for renewal of lamps, for it is

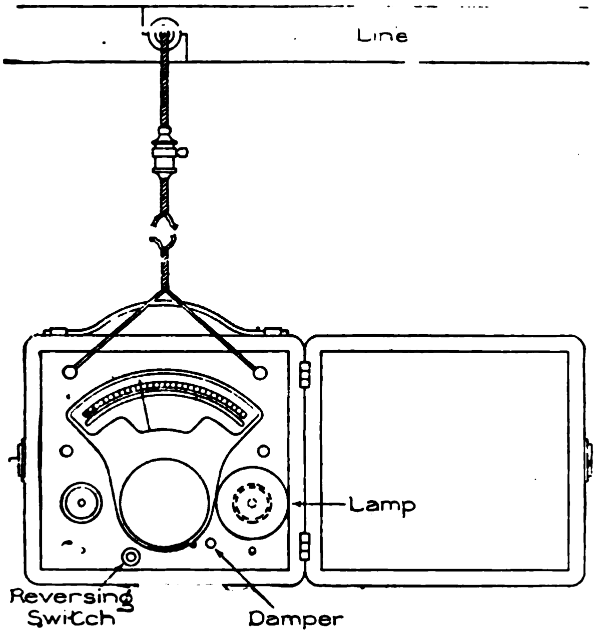


Fig. 1.

manifestly uneconomical to continue a lamp in service when it has so deteriorated that the current it unnecessarily consumes costs more than a new lamp.

A portable instrument to determine accurately and rapidly the watts per candle power required by a lamp, is of great value in selecting new lamps and in testing lamps in service. The General Electric Company has recently designed and introduced

Fig. 2.

the Thomson inclined coil portable indicating wattmeter to meet an increasing demand for instruments of this class.

All of the well known merits of the Thomson inclined coil instruments are embodied in the new wattmeter and the workmanship is of the highest grade. The present design was adopted after numerous experiments to determine the most advantageous arrangement to facilitate rapid testing of lamps without inconvenience to their users. On account of the rapidity with which readings may be made, the indicating wattmeter will also be found invaluable for testing lamps in barrel lots either with or without a photometer. The wattmeter will accurately indicate the energy used by small fan motors and is, therefore, particularly useful in comparing, for a customer's benefit, the relative amount of energy required by a fan motor and an ordinary incandescent lamp. Again by supplying the secondary of a transformer with current, its core loss may be easily determined by the indicating wattmeter.

For rapid connection the wattmeter is supplied with two special plugs, an Edison with T-H adapter, and a Westinghouse, thus providing ready means for connection to the three forms of sockets most generally in use. The lamp to be tested is inserted in one of the receptacles in the base of the instrument, and the proper plug placed in any convenient socket. Lead wires are provided suitably tipped at one end for insertion in the plugs and at the other for connection to the binding posts of the instrument. A small secondary plug arranged to fit the regular plugs and provided with two small binding posts is also supplied with every instrument. With this convenient device the power required by small motors or other apparatus may be conveniently measured.

The capacity of the indicating wattmeter is 150 watts. Lamps of any candle power up to 32 and of any voltage up to 150 may be tested, as may also any device, the consumption of energy in which is not over 150 watts at any voltage not exceeding

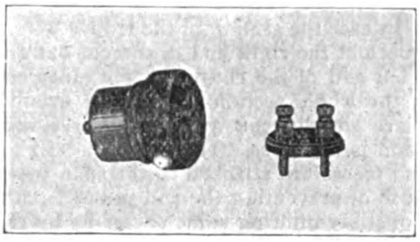

Fig. 3.

150. The fact that the instrument is equally well adapted for use on either direct or alternating currents, necessitates the use of only one instrument in stations using both systems.

On direct current circuits reverse readings should be taken to eliminate the possibility of any slight error which may be introduced in all instruments of this class by the presence of local fields. A special reversing button is provided to reverse the current in the instrument and lamp, without permitting the needle to fall back to zero. The usual convenience of reversing lead terminals is eliminated by the reversing button. When reversed readings are taken the mean of the two is, of course, taken as the final reading.

Another advantageous feature of the instrument is the damping device. A button is provided which releases the needle or pointer from the damping brake only when depressed. When the button is released the needle is held at the point of the last indication; therefore, if the current is turned off and then on again, or reversed, the necessity of waiting for the pointer to swing from zero to a state of rest is avoided and very rapid readings may be taken. The terminals, reversing and damping buttons are mounted on a vulcanite baseboard above which the graduated dial slightly projects.

The instrument is mounted in a finely polished carrying case, with snap lock. It is light and compact, the external dimensions being 7⅜ x 7 x 4½ inches. All parts are finished in polished nickel plate.

Puritan Electric Co.

Deputy Sheriff Gilligan last Friday took charge of the office at No. 11 Broadway, N. Y., of the Puritan Electric Company on executions aggregating $3,663, in favor of the Manhattan General Construction Company, on notes. The Puritan Electric Company was incorporated in October, 1896, with a capital stock of $100,000, and manufactured enclosed arc lamps. Stuart W. Wise was president and the concern was regarded by the trade as an adjunct of the Manhattan General Construction Company. The company was understood to be doing a large and progressive business.

The Live Wire Cut-Out.

THIS invention, which has been placed upon the market by The Live Wire Cut-Out Company, 35 Warren street, New York, consists in the combination with an overhead conductor forming part of a ground circuit and made of independent sections of a safety device or cut-out interposed between adjacent sections, whereby the current is cut off from the ground through a broken section.

The object of this device is to perform automatically and instantaneously the purposes of the invention, thereby rendering the broken section dead, removing the liability of accidents, and preventing the broken wire from having any live ends to come in contact with a person or animal, and, by thus completing a short circuit to the ground, to produce serious results. The device is composed of three pieces, and, upon a trolley wire, displaces the clip at each span. The end pieces, when properly suspended, engage the surface and bolts of the center piece, so as to form a perfect connection, and are held in place by the strain of the wire. In case the section of the trolley wire, held in place by the end piece at the right end of the cut-out and by the end piece at the left end of the cut-out at the other end of the section, breaks, the whole section falls to the ground uncharged; this takes place simultaneously with the breaking of the wire and the section is harmless. The insulated wires, by means of which the end pieces are attached to the span wires, are merely for the purpose of preventing the end pieces from falling to the ground and possibly injuring some passer-by by the blow.

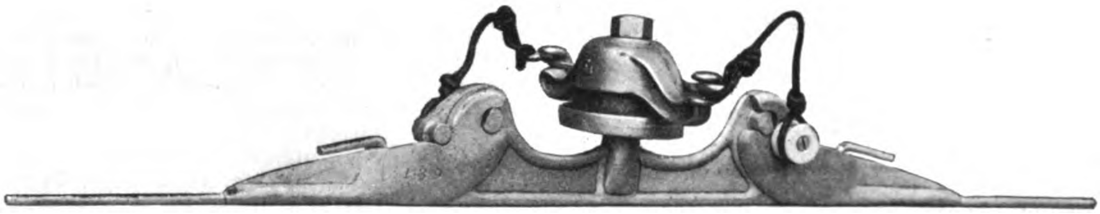

FIG. 1.—THE LIVE WIRE CUT-OUT IN ITS NORMAL POSITION ON THE LINE.

It renders the use of a wire (a smaller wire if desired) practicable until the wire is worn out. It offers special facilities for repairs without interference with the service of any section of the line, or with the machinery at the power house, a constant supply of electricity being maintained to all other points of the line through the various feed wires. On a single track road, the trolley car can by its own ~~momentum run by~~ the broken span, or, on a double track road, transfer, if preferred, the ~~trolley to~~ the other wire. It is useful in case of fire, for the accommodation of moving buildings, and for taking up slack. It is applicable to any wire.

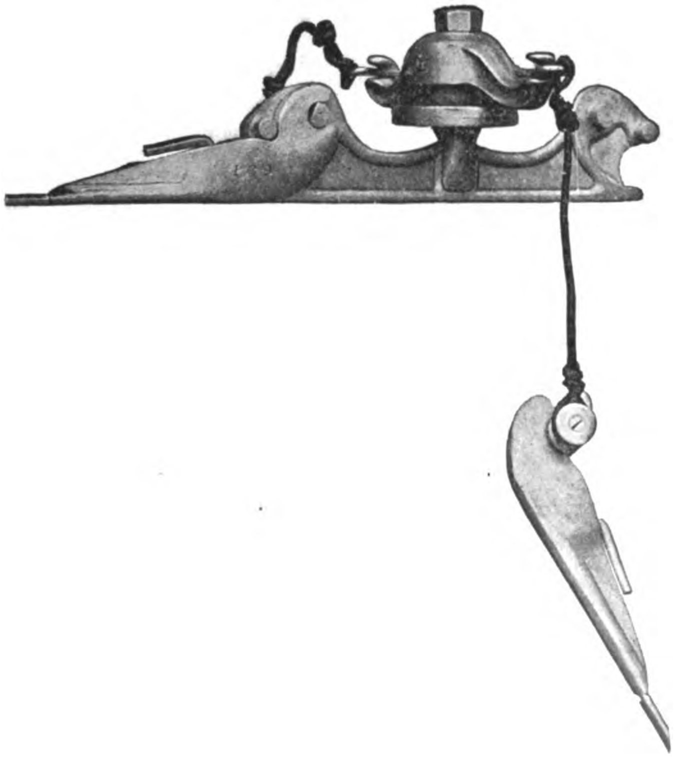

FIG. 2.—THE LIVE WIRE CUT-OUT IN ACTION.

The cut-outs have been in operation on the entire line of the Tremont and Suffolk Mills, Lowell, Mass., and also the line of the Washington Mills, of Lawrence. Thirty cut-outs have been used on the Albany Traction Company's road in Albany, and they have been endorsed by the electrical engineer of the Nassau Railroad Company, of Brooklyn.

A Decision As To Cement Lined Conduits.

The National Conduit and Cable Company inform us that Judge Townsend has sustained his original decree perpetually enjoining the Connecticut Pipe Manufacturing Company from making or selling cement lined conduit as covered by the Phipps patent, No. 395,584, owned by the National Company, except so far as the same relates to water pipes. The injunction restrains also all officers and agents of the defendant company, and the decree calls for an accounting of damages and profits.

CATALOGUES.

C & C Electric Co's. Iron-clad Dynamos and Motors.

THE C & C ELECTRIC COMPANY, 143 Liberty street, New York, have just issued a bulletin illustrating their ironclad dynamos and motors. These machines, which were placed upon the market during the summer of 1897, and have been illustrated in our columns, have met with pronounced favor and there is practically no limit to the uses to which they may advantageously be put. The sizes range from 5 to 50 h. p. or 4½ to 45 k. w. and are designed to run at either slow or medium speeds. They are wound for 125, 250 and 500 volt circuits. The motors are shunt-wound and the dynamos compound-wound. The closed-type machine is constructed so that it requires but the minimum of attention. Ready access to the brushes and commutator may be had, if necessary, by the removal of the solid iron covers fitted over the hand-holes in the end plates. The only difference in construction between the closed and open type machines lies in these hand-hole covers. The motors are unsurpassed for driving all classes of large machine tools, rolls, shears, hoists, cranes, elevators, draw-bridges, pumps, and similar machinery. They are also unsurpassed for driving lines of shafting through means of gears or direct coupling. The cylindrical casing forms the magnetic frame and is of soft cast steel of high permeability. The bearings are self-oiling and self-aligning and the field coils are wound with soft copper of 98 per cent. conductivity. The armature is of the slotted drum type with removable coil winding, which are uniform and interchangeable. The machines are equipped with the company's well known "reaction type" carbon brush holders, which permit of the reversal of the direction of rotation of the armature without injury to the brushes or commutator, and without any sparking. The efficiency of the machines is unusually high and the temperature of the windings never rises above 45 to 50° C. They are adapted for use in direct connection with vertical engines where a lighting unit is required which shall be thoroughly stable, require little attention and occupy but a small floor space.

The field regulator is of an entirely non-combustible type and the C & C automatic starting box fulfils all the requirements of the most rigid underwriters' specifications.

Kieley & Mueller Steam Specialties.

The new catalogue of Kieley & Mueller, manufacturers of engineering specialties, 7 to 17 West Thirteenth street, New York, contains numerous illustrations of the many high-grade steam appliances manufactured by the company, and the various uses to which they can be put. The following apparatus are described and illustrated in section: Low pressure reducing valves, vacuum pressure reducing valves, high pressure reducing valves, marine high pressure reducing valves, back pressure valves, standard steam traps, extra heavy steam traps, strainer connections, special low pressure balanced steam traps, champion return steam trap and boiler feeder, positive acting pump governor, water pressure regulator, tank pump controller, combined pressure regulator and water feeder, improved climax damper regulator, Climax damper regulator, multi-tubular oil and grease extractor, improved steam separator, standard tubular water arch for steam boilers, Empire drain trap. The catalogue contains many diagrams illustrating the use of the apparatus.

The Central Telephone and Electric Co.

The Central Telephone and Electric Company, of St. Louis, Mo., have issued a new illustrated circular, setting forth the advantages of their high-grade telephones, telephone parts and exchange switchboards. Their "Central" transmitter is claimed never to get out of adjustment, as neither springs nor carbon dust are used in its construction. The company can supply complete sets of apparatus for exchanges, including the line equipment, such as poles, wires, cross-arms and insulators. Their "Central" exchange and toll-line switchboards embody many novel and useful features.

Ward Leonard Electric Co. Porcelain Lined Outlet Boxes.

THE Ward Leonard Electric Company, Bronxville, N. Y., have just issued their tenth catalogue, this one illustrating their cast iron outlet boxes, with porcelain lining. It is claimed that by means of the company's special enamel the contents of the outlet boxes can be permanently insulated from the cast iron of the box, so as to withstand 2,000 volts alternating. The insulation is absolutely moisture proof and does not depreciate in any way with time. It will withstand an exceedingly high temperature if necessary; no vibration can affect it, and no chemicals have any influence upon the insulation of the enamel. The Ward Leonard Electric Company is the only concern in the world, so far as we know, who use a special porcelain of this kind of their own manufacture, and who are prepared to undertake special applications of enamel insulation. The merits of these outlet boxes are rapidly being recognized by electrical engineers and contractors, and over 81,000 of them were installed in New York City alone during 1897; 14,000 of which were used in the Astoria Hotel, 5,000 in the Columbia College buildings, 4,000 each in the New York and the Metropolitan Life Insurance Companies' buildings and 3,000 in the Manhattan Hotel.

MICHIGAN PIPE COMPANY'S CREOSOTED WOOD CONDUITS.—In a recent catalogue of the Michigan Pipe Company, Bay City, Mich., the advantages in the use of creosoted wood conduits, treated by the Bethel process, are stated as follows: "It does not destroy insulation. It has but one joint in eight. The holes are straight and smooth. Cables are not scratched in pulling them through. When struck with picks, only a hole the size of the pick is made. Several joints cannot be broken by a blow, as is the case with some other materials. It does not require a concrete foundation. It does not affect the cables. It will last forever. Wires are reached between manholes more easily than in any other conduit. Construction takes less time. It can be laid around unmovable obstacles encountered in trenches, at the same cost per lineal foot as straight conduits. The creosote will prevent vegetable growth from reaching the conduits." The pamphlet gives valuable information about the history of creosoting, the nature of the substance and process used and the durability of wood thus treated. The company also manufacture the Wyckoff water pipes, which are not subject to electrolysis, as has been shown by tests and years of experience.

The Cambria Steel Rails.

WE have just received Vol. II. of the catalogue of the Cambria Iron Company, Philadelphia, Pa. This beautifully illustrated, cloth covered book measures 11½ x 12 inches and contains over forty full-page illustrations of steel rails and tie plates manufactured by the company. Each plate embodies an elegantly executed working drawing, with all necessary dimensions and weight per yard and mile. The book also contains useful information about materials for track construction and is one of the most complete and carefully executed catalogues which has come to our notice. It is a creditable production and speaks well for the meritorious goods manufactured by the company. The book should find a place in every well-selected engineering library and in the office of railway superintendents and engineers.

NEW ENGLAND NOTES

THE LIVING AGE FOR 1898. In another column will be found a prospectus of this standard periodical. Founded by Eliakim Littell in 1844, it has steadily maintained the reputation gained with its earliest issues of being the most complete representative of foreign thought as expressed by its greatest exponents. It is to-day a faithful reflection of almost all that is substantial and truly valuable in the passing literature of the world, embracing as it now does in its Monthly Supplement, American as well as foreign literature. While its pages show the same wise and judicious discrimination which has ever characterized its editorial management, the scope of the magazine has been widened, its size increased and its price reduced, so that increasing years seem only to add to its vigor and value. To those whose means are limited it must meet with especial favor, for it offers them what could not otherwise be obtained except by a large outlay. Intelligent readers who want to save time and money will find it invaluable. The Living Age is published weekly, and the price is now but $6.00 a year. To all new subscribers for 1898 are offered free the eight numbers of 1897, containing the opening chapters of the new serial, "With All Her Heart," described in the prospectus.

NEW YORK NOTES.

MR. FRANK B. WIDMAYER, No. 482 Western Boulevard, New York City, formerly with the Ball Electric Light Company and late of the firm of Burkart & Widmayer, has recently bought Mr. Burkart's interest and will conduct the business of electrical engineer and contractor at the above address and will give particular attention to electric gas lighting, burglar alarm and repairs on medical batteries, electric motors, etc. He will carry a full line of electrical goods and novelties, and will act as the uptown agent for the Acme electric adjustable lamp and supplies and the Iver Johnston line of '98 bicycles. He invites his many customers and friends to call in and examine his line of electrical and bicycle novelties.

MONTAUK CABLE.—A large number of the prominent jobbing houses throughout the country are interesting themselves in the products of the Montauk Multiphase Cable Company, with the idea of introducing their new and ingenious thermostatic cable to the electrical trade.

M. C. HENRY & CO., of New York City, are enlarging their plant and making some extensive improvements. Their new steel stone shed, which is about 50 feet wide, is to be extended about 70 feet in length. The metal work, which consists of the steel framework of the building, the covering upon the roof and sides, and the metal runway for a traveling crane, is being furnished and erected by the Berlin Iron Bridge Co., of East Berlin, Conn.

HARRISON, N. J.—Among the extensive improvements now being made by the Benjamin Atha & Illingworth Company, at

Harrison, N. J., is a new steel edifice known as the Tower Building. This building is 30 feet square and about 40 feet high. Thirty-five feet above the ground is a circular trolley track carried by the roof trusses. The framework of the building is of steel throughout, and the siding and roofing of corrugated iron. The complete contract for furnishing and erecting this building has been given to the Berlin Iron Bridge Company, of East Berlin, Conn.

THE VACUUM GAS ENGINE, POWER AND MACHINE COMPANY, of Mount Holly, N. J., has filed articles of incorporation. The object of the company is to manufacture gas engines, a recent patent of Thomas Small, of Camden; also dynamos, electrical supplies, water wheels and other kinds of machinery. The capital stock of the company is $100,000. The incorporators are S. Prentice Comegys, Smithville; Chas. A. Wilson, Philadelphia; John B. Davis, Bradford W. Storey, John M. Huff, Mark R. Sooy, Mount Holly; Francis Fennimore, St. Davids, Pa., and Thomas Small, Camden.

SOUTHERN NOTES

B. & O. CHANGES.—On March 1, Edward S. King, now commercial freight agent of the Baltimore and Ohio Railroad Company at Baltimore, will be transferred to Philadelphia with the same title and duties. His successor in Baltimore will be H. W. Atkinson, now chief clerk to General Freight Agent Galleher. J. R. Bell, of the general freight office in Baltimore, will succeed Mr. Atkinson as chief clerk in the freight department.

WESTERN NOTES

MR. CYRUS ROBINSON, who recently resigned from the Ridgway Dynamo and Engine Company, has associated himself with the Hammond Manufacturing Company, of Portland, Ore., who manufacture stamp mills, ore crushers, and who are contractors for complete mining plants. Mr. Robinson, who is an expert civil and mining engineer as well as an electrical engineer, intends to push the electric equipment of mines, long distance transmission work, etc., and believes that there is a large field for development in the Northwest. Mr. Robinson is well known in the East and Middle States, and his many friends will wish him well in his new sphere of enterprise.

THE WESTERN ELECTRIC COMPANY manufactures a very superior disc Leclanche porous cup cell, especially adapted for bell and annunciator work. They make the batteries complete or furnish the porous cup without zinc or glass jar.

SWARTS METAL REFINING COMPANY, 20 North Desplaines street, Chicago, have requested us to mention the fact that they are not in any way connected with the Swarts Iron and Metal Company. The two concerns are quite distinct, on different lines, and have at no time been connected in any way. The Swarts Refining Company are in business at the old stand and ready to fill any orders that may be entrusted to them.

MR. FRANCIS M. RAYMOND, general sales agent of the Chas. E. Gregory Company, Chicago, reports that among their recent orders for apparatus was a shipment of generators and motors to a large sugar refinery in the Hawaiian Islands, and a lighting and power plant for the Alaskan gold fields.

THE JONES BROS. ELEC. CO., of Cincinnati, has increased its capital stock from $200,000 to $220,000.

THE CENTRAL ELECTRIC CO. has taken the Western agency for the Erickson outlet insulator, brought out to meet the demands of engineers for a thorough and perfect protection at the ends of iron armored conduit outlets. It very effectually and thoroughly prevents possible grounding of the wires on the iron conduits and has met with a very ready sale.

FISHER ELECTRIC CARRIAGES.—That the electric motor vehicle has come to stay is evident from the fact that Messrs. Sipe & Sigler, manufacturers of the Willard storage battery, have just closed a contract extending over a period of three years with the Fisher Equipment Company, of Chicago, for Willard storage cells amounting to $238,000 for motor vehicle propulsion.

CINCINNATI, O.—Bids for the construction of the new Edison Electric Light Building at Plum and Charles streets have been opened. The contract was awarded to James Finnegan and associates at their bid of $117,000. The building will be composed of iron and brick, two stories high, covering an area of 107 x 250 feet. A Chicago and St. Louis firm each bid, but their lowest proposition was $140,000. Work began Monday and will be completed in 120 days.

The Electrical Engineer.

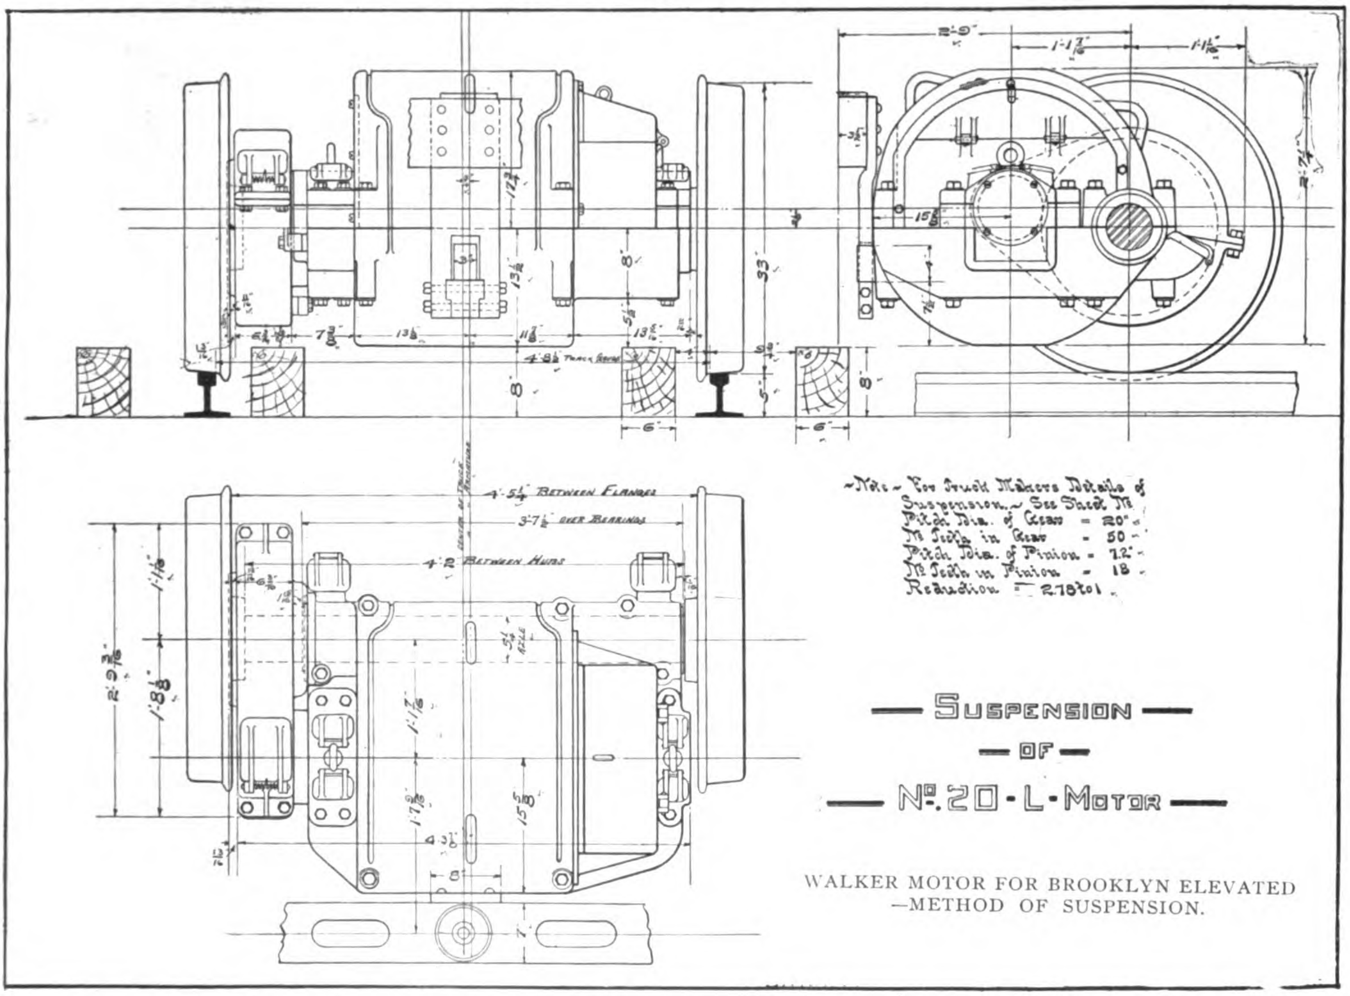
Vol. XXV. MARCH 3, 1898. No. 513.

ELECTRIC TRANSPORTATION

Electrical Equipment of the Brooklyn Elevated Railroad.

ONE of the most important announcements ever made in regard to electric traction work was given publicity last week. It is stated that the Brooklyn Elevated Railroads have closed contracts with the Walker Co., of Cleveland; the Sprague Electric Co., of New York City, and the Pullman Car Co., of Chicago, for a complete electrical equipment of their system, to be undertaken without delay; and we now learn with great pleasure that the work is being proceeded with promptly. It is in many ways a memorable event, and there is a peculiar fitness in the electrical conquest of the elevated roads of Greater New York in the first year of its corporate existence. While but in Brooklyn the great bulk of travel is concentrated in about four hours, two in the morning and, refluently, two at night. During the rest of the day single cars will normally answer all purposes, or, at most, trains of two. This led to the adoption of the Sprague ingenious "multiple unit" system, which gives a whole train the characteristics of any separate car, and allows the train to be handled from either end, and the cars to be hitched up in any combination regardless of end relation.

Prof. Sidney H. Short, whose apparatus is being furnished by the Walker Co., of which he is the chief engineer, has been peculiarly fortunate in being able to supplement his long experience as an electric railway inventor by his tests on the West Side Elevated in Chicago. He brings to the Brooklyn work the matured results of all the data secured in Chicago. It is now at least a year since he built his big motors for that work, sent them out to Chicago, and began a series of special studies and experiments the object of which was to detect any latent weaknesses and correct whatever deficiencies might be developed. Tremendous currents were thrown on and off, the tests of acceleration were pushed to the utmost degree, and the ability of electricity to take care of heavy travel was tried in every



WALKER MOTOR FOR BROOKLYN ELEVATED —METHOD OF SUSPENSION.

the honor of receiving the pioneer equipment falls to the Borough of Brooklyn, as did that of being prompt to install the trolley, there can be no doubt that the elevated system on Manhattan Island must be profoundly affected and must perforce soon follow suit. When we remember how long and fiercely the prize of equipping the elevated roads has been struggled for, the companies now receiving the contract are certainly to be congratulated on their success, coming as it does at so striking a stage in the expansion of the enlarged metropolis.

It is perhaps not generally recognized that there are profound differences between the two elevated systems of Brooklyn and Manhattan, in respect to the service. There is a more or less steady stream of travel on the New York roads all day long, possible manner. Fortified by highly successful results, Prof. Short was able to submit a well rounded scheme to the authorities of the Brooklyn Elevated, at the "psychological moment" when something had to be done; and after a thorough investigation by their engineers his plans have now been adopted. Prof. Short also indorsed warmly the unit control system as meeting the peculiar conditions which demand ten car trains morning and night for the 60 per cent. of patronage then to be handled, and which, as already stated, include the necessity of working on a narrow basis during the middle part of the day with a minimum of rolling stock in service.

Through the courtesy of the Walker Co. we are able to illustrate herewith the Short motors for the Brooklyn "L" roads,

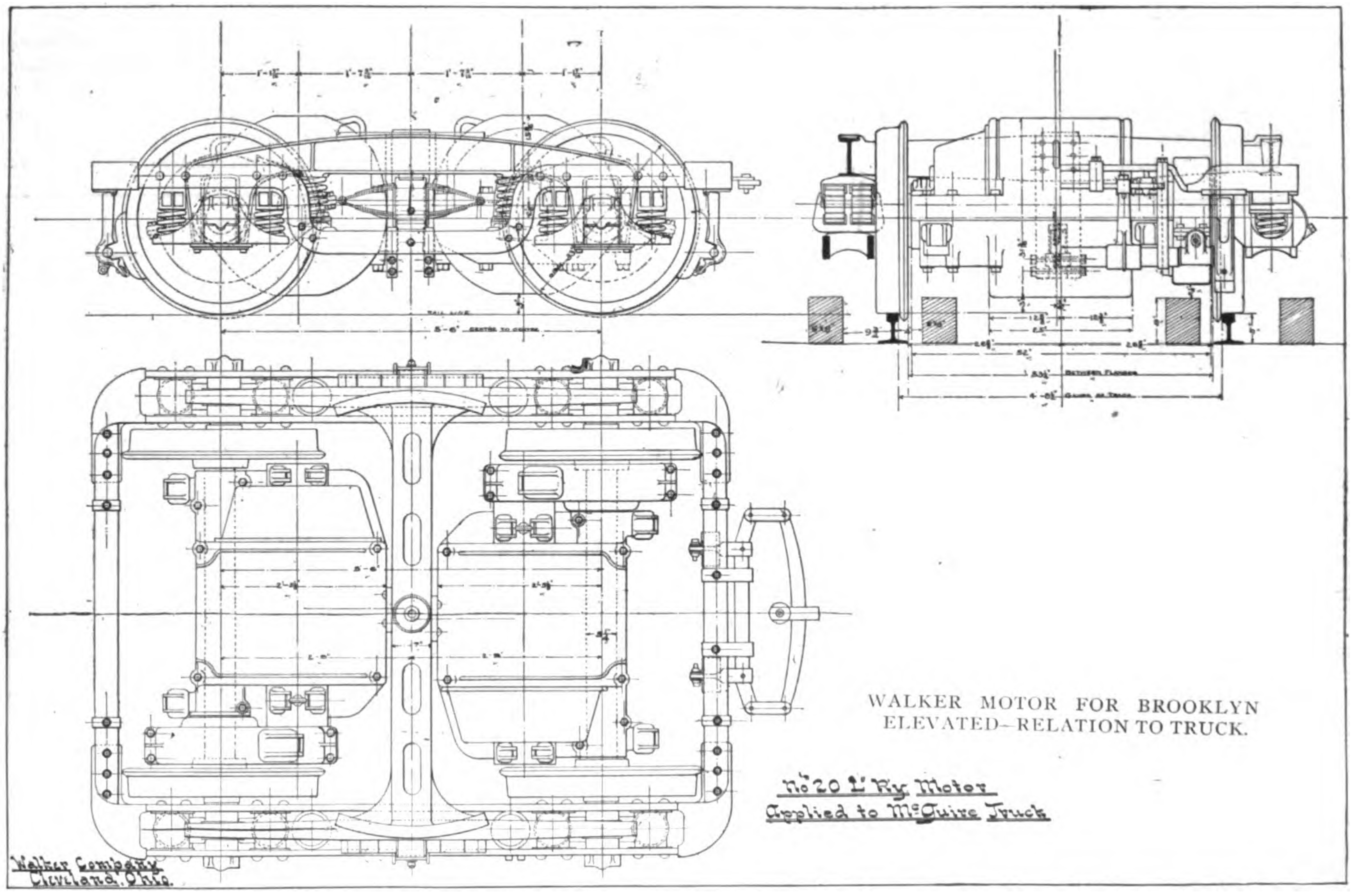
showing the method of suspension; also the relations between motor and truck. The company have received orders for fifty motors, making twenty-five car equipments, two motors to each car; and is to have the work ready for operation in ninety days, further contracts coming for 100 more motors; making 75 car equipments in all. The trucks are of McGuire make. Each Short motor is of 80 h. p., all steel, 4-pole, the full armature speed being 450 revolutions per minute. The motors are so built that the steel tires can wear down 1½ inches and still leave safe clearance. They embody all the improvements and perfections suggested by Prof. Short's work in Chicago, and are confidently relied on to make a fine showing and to settle the whole question for New York. The bearings are very massive, being 10 inches long and 4 inches in diameter. The gears are 5-inch face and 2½-inch pitch. Every bearing is hard bronze. The axles are 5¼ inches.

As will be noted, the magnet frames are circular, being cast in a perfect ring, like that of a direct-connected generator; in fact, they are quite distinctly of a generator type in massiveness and solidity. Bolted on the inside of the frame are the four laminated steel pole pieces with pole shoes on them, as in a generator. The upper half of the ring and the armature lift out from above. The lower half is suspended, being attached to a girder which goes across from one side to the other, as shown. On each side or end of the shaft is an oiling box bolted down, with openings on each side through which waste is pushed. The box is filled with oil which is taken up by the waste, and this in turn lies against the armature shaft, and wipes and oils it all the time. The brasses for the armature are in two parts, one above and one below, adjustable to take up wear, like car brasses. There is a lid over the commutator to prevent dust from getting in, etc. Not only are the armature bearings so protected and housed as to use the same oil over and over again from the end pockets, and to avoid drip, but the axle as it passes through the frame of the machine takes up oil from the wells and returns it in the same way. The gear housing is of heavy steel, bolted tightly together, and provision is made all around against oil spilling. The openings toward the wheels are also protected by a felt washer ring fitting close against the flange of the gear case. In fact, although the whole thing is run in oil and profusely lubricated, the chance for escape of oil is reduced to a minimum. An equally important matter is the care taken to prevent the oil from getting into the motor itself.

All the windings of the motors, both field magnets and armature, are bar copper. There is no wire in the machine at all. The entire insulation on this copper bar conductor is mica and asbestos. No cotton or cloth is used at all. In other words, the insulation is absolutely fireproof; it could be put in a fire and would sustain no hurt. The Walker Co. have made a very intimate study of the use of mica, and use it generously to the best advantage in these machines, and this in spite of the fact attested in the Chicago work, that they run remarkably cool. Still, it is a wise thing to be on the safe side, in view of the heavy work that may fall to the lot of such machinery. It is obvious that motors propelling heavily loaded cars, and giving acceleration up to two miles per second, every minute or so, are under a heavy strain.

In the armature, which is built up like that of a generator, the "windings" of bar copper are sunk into very deep slots. A strip of thick asbestos is put over the windings, and the binding wires are also sunk in to such an extent that the teeth of the radial slots of the laminated core project at least three-eighths of an inch beyond the bar copper windings and their insulation. Both the armature and the fields secure very thorough ventilation from a free circulation of air.

The cars equipped with these motors are guaranteed to have a speed of about sixteen miles an hour, schedule time, with station stops; or if four of the motors are grouped in one car for special purposes, eighteen miles an hour, including stops. It is noteworthy that at one time the Brooklyn Elevated officials and engineers inclined to the use of electric locomotives, but they were soon convinced of the superiority of the methods now adopted, the chief reasons being the infinitely greater flexibility of the service and the securing of greater power for a train without added weight on the structure of the road. The gain to the Brooklyn Elevated in capacity will reach, it is said, 50 per cent., while the public which has been lured away by the swifter and more frequent cars of the surface roads, will be attracted back again by the clean, cheerful, handsome and swift trains on the elevated. For the present, current at 500 volts will be taken, however, from existing street railway power plants, until the increase in the service necessitates other sources of supply. The cars are, it is understood, to be run over the bridge to New York, and will thus offer further facilities to Brooklynites hav-



WALKER MOTOR FOR BROOKLYN ELEVATED—RELATION TO TRUCK.

ing business west of the bridge. The first part of the equipment will probably go into operation about June 1.

Austrian Narrow Gauge Electric Locomotive.

THE Vereinigte Elecktricitäts-Actien Gesellschaft, of Vienna, formerly B. Egger & Co., have recently built an electric locomotive for the brewery of Dr. Schaup, of Zipf, Upper Austria (between Wels and Salzburg). It is intended for hauling two or three freight trailers, as well as conveying passengers, for whom seating capacity is provided in the cab of the locomotive itself, back and forth from the brewery to the railroad station.

The tracks are narrow gauge, namely, 2¼ feet. The locomotive in going from the station to the brewery has to ascend a considerable grade, but can make the return trip without using any current, electrical energy only being required for start-

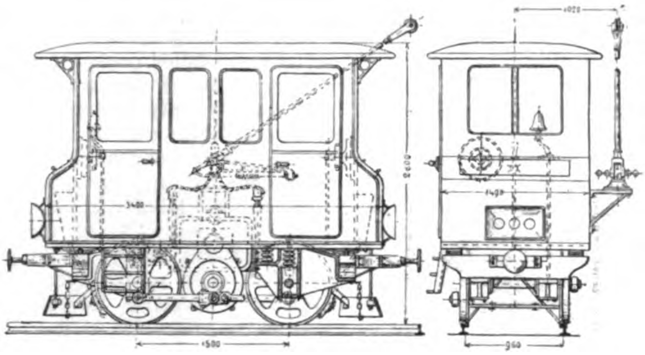


FIG. 1.—NARROW GAUGE LOCOMOTIVE.

ing. The wheel-base measures a trifle less than five feet, so small, that the sharpest curves can be rounded without the least danger. The speed of the locomotive is 6¼ miles per hour. Its driving wheels are 27½ inches in diameter and the load is about 13 tons. The 15 h. p. series motor makes 290 revolutions per minute when fully loaded, and the e. m. f. of the circuit is 500 volts. The weight of the locomotive, including the motor, is about nine tons. With its weight and drawbar pull the locomotive easily ascends the maximum grade of 24 per cent.

The Truck.—In the construction of the truck the motor itself has been made use of. On the lower portion of the motor, on both sides, two strong U-shaped cast steel beams are attached, so that four arms extend from the motor. These arms are so shaped as to form supports for the axle bearings, on which they rest by means of strong spiral springs, as shown in Fig. 1. Each set of arms carries a crossbeam on which the bumper and chain are mounted. The entire base and motor are thus protected by springs from shocks. This construction was the device used by Mr. Eikemeyer.

The transmission of motion from the motor to the driving wheels is accomplished as follows: On each end of the shaft of the motor is a bronze gear wheel. These are geared to a toothed crank disc whose common axis is located beneath the motor. From these crank discs the rotary motion is transmitted to the wheels by means of connecting links. This arrangement enables both axles to be driven by one motor, which is a desirable feature in ascending heavy grades. The crank pins on these two crank discs are placed at an angle of 90 degrees with respect to each other in order to avoid any uneven mass acceleration, which results from the arrangement used. The transmission of motion is uniform and the arrangement very satisfactory in this respect.

The Motor.—The motor, as already stated, is of the two-pole series type. It is entirely enclosed, and thus protected against dust and moisture. The magnetic frame consists of two parts; the upper portion is bolted to the lower one and can be raised through the floor of the car, and the lower portion, as already described, forms a part of the truck. The commutator may be reached through small hinged doors in the upper part of the frame. A slotted armature is used, wound with formed coils insulated with mica.

The Cab.—The upper portion or cab is constructed of wood, is strengthened by means of flat and angle irons and covered on the outside with tin. The roof is 9¼ feet above the tracks and the width is nearly six feet. At both ends the locomotive curves out and in this space the sand box and rheostats are located. The interior of the locomotive is divided laterally into two parts by two rows of seats placed back to back. These seats may be so turned as to face towards the front of the cab. This makes it possible to open the trap in the floor in order to reach the motor.

The Brakes.—The braking mechanism of the locomotive is represented by an ordinary chain brake, and the operation can be performed at each end. All four wheels are braked. The braking lever has a Riedel signal bell attached to it, which can be sounded without loosening the hold on the lever. The sand boxes are located, as already referred to, in the outward extension at the two ends of the locomotive. From here the tubes are led very close to the points where the wheels come in contact with the rails. Special attention had to be paid to the operation and construction of these sand boxes on account of the steep grades. Failure of operation, especially in winter, might cause serious accidents.

Electrical Equipment.—This consists of a brake handle, sand box lever and controller at each end. The controller is screwed against the wall and is used for starting the motor and regulating its speed; this is done by cutting resistance in and out of the circuit. By means of the controller the armature can be short-circuited and act as an electrical brake. Besides the apparatus mentioned, there are the necessary switches and safety devices for the lighting equipment.

The latter consists of two incandescent lamps attached to the ceiling and two signal lanterns, one at each end, and each containing three incandescent lamps. The method employed for lighting the locomotive is as follows: Going in one direction, the signal lantern at that end and the two interior lights, and going in the other direction the other signal and the two interior lamps are used. If the locomotive, however, has a trailer attached, then the signal lantern and only one interior lamp, besides one lamp in the trailer, are lighted. The combinations are controlled by two switches.

Current Conductors.—The current is supplied by an overhead trolley. The trolley pole is not, as is commonly done, attached to the roof of the locomotive, but to a bracket at the side. This construction was adopted, because the locomotive, which was in itself 9¼ feet high, had to pass through tunnels 9¾ feet in height, which made the use of the trolley pole on the top of the car an impossibility. The trolley wires were already in place

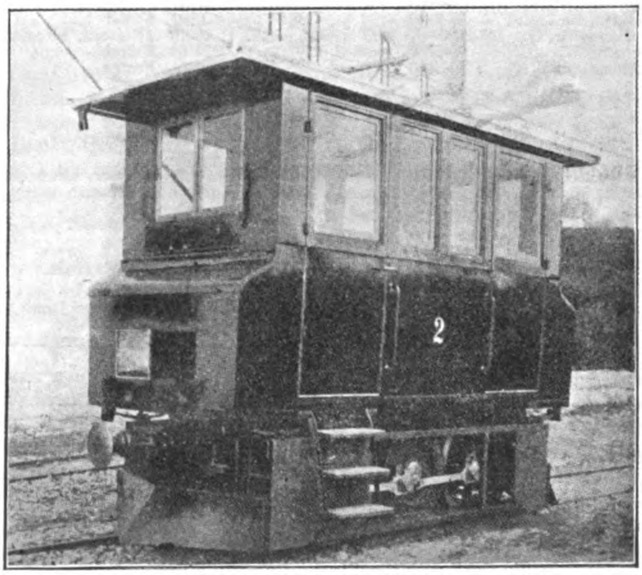

FIG. 2.—NARROW GAUGE LOCOMOTIVE.

when the locomotive was ordered and delivered. Below the trolley stand lightning arresters and main fuses are located. These are well protected against the weather and the fuse is enclosed in an earthenware box. At each end of the locomotive there is an attachment for clearing the tracks. The crank discs and gears are protected by cast iron casings, which are so shaped as to allow free movement of the crank pins, which take up sufficient oil on their under side to have the gears run continuously in oil. These casings are so constructed as to prevent the entrance of dust.

The entire truck is surrounded with a tin casing, which is

constructed in such a way as to allow access to all parts through small apertures. All these precautions enable continuous runs to be made with perfect safety and reduces the necessary attention to a minimum. We also wish to call attention to the remarkably small current consumption which is with a load of 13 tons on a 24 per cent. grade and a speed of 3¾ miles per hour, 24 amperes at 500 volts. A perspective view of the locomotive is shown in Fig. 2. The above illustrations and data were taken from the "Zeitschrift für Elektrotechnik," Vienna.

Municipal Electric Lighting.[1]—II.

BY PROF. JOHN R. COMMONS.

It will be seen that the labor cost in the New York City private plants is $3.88 per arc less than in Detroit and $16.71 less than in Chicago. This difference is accounted for in two ways: first, by the much larger output per station in New York City; second, the higher wages, shorter hours and, consequently, larger staff of employees in the public plants. In the larger cities, on the other hand, the larger output and larger units in boilers, engines and dynamos would tend to reduce the labor cost per unit of product. The case of Allegheny, with its extremely low labor cost notwithstanding short hours is noteworthy.

It should be said as an offset to the low wages and long hours in smaller places, that the work is much easier than in large plants. When one fireman and one engineer run a small plant of 100 arcs in conjunction with water works, probably less than one-half their time is employed in actual work. The cost of living, too, is much less than in cities. Consequently the urgency for both high wages and short hours is relatively less.

WATER WORKS AND ELECTRIC PLANTS COMBINED.

A very important advantage in a small town is the ability often to combine the electric lighting plant with the water works. That most industrious opponent of municipal ownership, Mr. M. J. Francisco, of Rutland, Vt., in his astounding pamphlet, "Municipal Ownership, Its Fallacy,"[2] is constantly insisting on the duplicity of municipal officials who charge the salaries of firemen, engineers and superintendents of electric works to the water department. In all such cases he forthwith corrects the dishonest officials by charging all the wages and salaries in the water works to the electric light department. The relative honesty of the two methods may be judged from the following typical cases:

The village of Batavia, N. Y., owning and operating its water works system, decided, in 1893, to add an electric lighting outfit to the plant. An addition was made to the water works building for the electrical machinery, and a new boiler was erected. Two engineers, at $65.75 per month each, had been all the force needed for the water works. For electric lighting there were added one electrician at $65, one trimmer at $45, and one fireman at $45, and the engineers' salaries were increased $5 each per month; making the total additions $165 per month, $1,980 per year, or $19.22 per arc lamp per year. The combination with the water works saves the salary of one engineer, $65 per month, less extra pay to water works engineers.

The City of Dunkirk, N. Y., installed an electric plant with its water works in 1888. The water works staff had been: Two engineers, $70 each; two firemen, $50 each; superintendent and assistants, $165; total, $405 per month, or, with $350 per year for clerk and collector, $5,210 per year. When the electric plant was added with an additional boiler, a trimmer was employed at $55, and the firemen were given $5 extra pay; total, $65 per month, which, with $133.62 extra labor on lines, made the total labor cost $913.62 in 1897, or $12.18 per arc. As a matter of fact, the Dunkirk labor cost is only $133.62 a year more for both water supply and electric lights than it had been for water supply alone, because one superintendent at $100 a month now does the work formerly done by superintendent and assistants at $165 per month, and the total labor cost for both departments in 1897, including extra labor, was $5,343.62, against $5,210 for water alone before 1888. But this saving of $65 per year in the superintendent's force has been properly credited to the water department, and the extra expense for electric lighting has been figured as above at $913.62.

In considering the cost of operation in these plants connected with water works, the conscientious defender of the higher charges of private plants is justified in pointing out that they cannot be taken as a fair basis of comparison with private plants operated alone. He, however, would hardly go as far as Mr. Francisco and claim that their operating accounts were dishonestly compiled, nor would he adroitly add the water account to the electric account.

The officials in these cities have prepared these statements with a definite purpose, namely to show to other cities having water works plants the very slight additional expense that they would incur by adding an electric plant to their water plant. From this point of view their statements are straightforward and correct. They demonstrate beyond question the decided advantage that every small city with a water plant has in espousing public ownership and operation of electric works, provided the two can be incorporated in one establishment.

There are many small villages now enjoying electric lighting which would probably not have secured this privilege had not the people as a whole, in their corporate capacity undertaken it. Mr. Foster, in reviewing the list of 34 towns whose costs he has tabulated, and showing that 13 have less than 3,000 inhabitants, five have between 3,000 and 5,000, four between 5,000 and 10,000, seven between 10,000 and 20,000, four between 20,000 and 30,000, and only one is of the first class, or over 1,000,000, remarks that "somewhat over half the number are places where it is doubtful if a commercial or private plant could be made to pay under any circumstances." If this is so, the question at issue is not one between public and private ownership, but whether they shall have electric lighting at all. If they have made a success of it, and have produced light at a cost no greater than other cities are paying private companies, this is certainly to the credit of the principle of municipal ownership under such circumstances if under no other.

PREVIOUS INVESTIGATIONS CRITICIZED.

In attempting to make a comparison of the actual operations of municipal and private ownership of electric lighting plants in the United States that shall be at the same time fairly exhaustive and fairly accurate, one is confronted with the magnitude and expense of the undertaking. Nothing less than a governmental bureau can adequately undertake so large an inquiry. It must, therefore, be to the greatest satisfaction of the public to know that the United States Department of Labor, under the supervision of Carroll D. Wright, has undertaken exactly such an investigation. In view of this prospective mine of information, I shall not undertake to consider the whole field, but shall devote my attention to a few municipal plants which I have been able carefully to study personally, and to a critical examination of some of the more important statistical inquiries that

[1]Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec. Engr.
[2]Published by the author, Rutland, Vt., 1895.

have been made hitherto. These are three in number: that of Mr. H. A. Foster, that of Mr. J. Francisco, and that of Prof. Frank Parsons.*

The first two are antagonistic to municipal ownership, while the latter favors the proposition. I have tabulated below the results obtained by these three writers as to the cost per lamp hour and the cost per year of arc lighting in all cases where two or more estimates for the same city are given. These reports are not all made upon the same unit as a basis and I have been compelled to make two sets of computations in order to bring them to the same basis for comparison.

I have selected these three writers because the opponents and the advocates of municipal ownership throughout the country seem to rely upon them for their data and arguments in maintaining their respective opinions. It will be seen that they reach the most contradictory results. Mr. Francisco far exceeds Mr. Foster in his high estimates of the cost of municipal operation, and Mr. Parsons, while his estimates are materially lower than either, is yet in such cases as I have been able to examine, above the estimate made by the municipal officials themselves.

(Table I. will appear in next part of this article.)

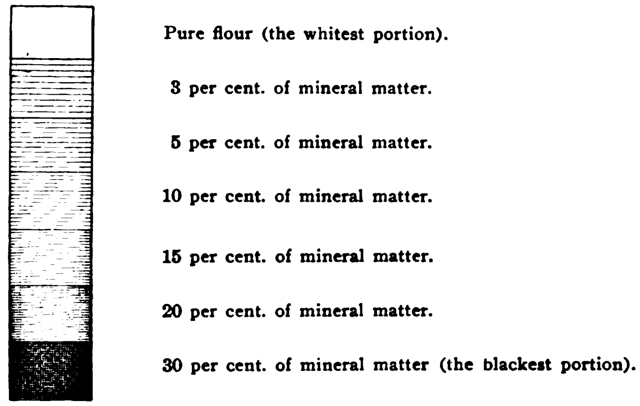
Researches by Means of X-Rays on the Adulteration of Flour.

BY A. BLEUNARD.

DR. LABESSE and myself having had occasion to analyze flour containing as much as 40 per cent. of foreign mineral matter, have tried to discover this adulteration by means of the X-rays, a research which has been made before, but which we wished to perfect and make as sensitive as possible. The nature of the mineral substances present in the flour, consisting of sand reduced to a powder, and insoluble lime salts, principally chalk, we decided a priori to look upon our experiment as one that could be easily performed successfully. The experiment was a complete success when the conditions exist as indicated below.

It is claimed to be difficult to compare the shades when they have great variation, and this is why, in the improvement made by Foucault on the Bouguer photometer, this scientist has obliterated all black or luminous lines, due to the separating screen between the two luminous sources to be compared. We thought of operating in the same manner and to superimpose, on the photographic plate or the fluorescent screen, without discontinuity, the two images of the flour to be compared, pure flour on one side and adulterated flour on the other. To this simple arrangement we owe all the sensitiveness of our method.

We placed on an ordinary photographic plate of gelatine-bromure, a small pasteboard box, of rectangular shape, from which the top and bottom are removed, retaining consequently only the lateral walls, of about one centimetre in height. We divided the box into two equal parts, by means of a small rectangle of convenient dimensions, cut from a visiting card. This done, we then filled one of the compartments with the pure flour, the other with the adulterated flour; we removed with precaution the separating partition, and we lightly tapped the box with the finger, so as to fill up the small empty space which fills



SCALE OF TINTS SHOWING THE ADULTERATION OF FLOUR.

with flour, without sensible mixture. The whole is covered with a sheet of tin foil, with a quite narrow rectangular slit cut in it, and placed perpendicular to the section of separation between the two flours. It only remains to expose it to the action of the X-rays and to disclose the image.

The duration of exposure must not be too long, and naturally depends on the apparatus one employs. Two minutes was sufficient for that which we experimented with. Too long an exposure has the disadvantage of producing too dark tints, the comparison of which is impossible; too short an exposure produces, on the contrary, too faint tints.

This method has permitted us to disclose with certainty the presence of three per cent. of foreign mineral matter in flour, this matter being composed of equal weights of very fine sand and chalk. The adulteration can be detected much easier when the proportion of mineral matter is greater.

Besides, it is possible, once the fraud is known, to tell with considerable exactness the quantity of mineral matter introduced. It suffices to compare the tint obtained with an increasing scale of tints, obtained by introducing into pure flour known quantities of foreign mineral matter. We further wish to remark that the tints vary with the nature of the mineral matter employed in the adulteration, and that this method of quantitative analysis can only be approximate. The accompanying engraving is an exact reproduction of a scale of increasing tints, obtained by placing in succession, in the same kind of a box and using the above precautions, successive samples of pure flour and of flour progressively mixed with mineral matter, such as sand and chalk.—La Nature.

A Rhythmic Dilation of the Heart Discovered by the Roentgen Rays.

A special dispatch from Paris of February 12 says that Prof. Bouchard has discovered a new movement of the heart by means of the Röntgen rays. It is a rhythmic dilation during respiration and is not connected with the ordinary movements of the heart. It appears to arise from a diminution of pressure in the interior of the thoracic cage during inspiration.

GEORGIA.—It is proposed to release the death trap under murderers being hanged by means of an electric push button attachment.

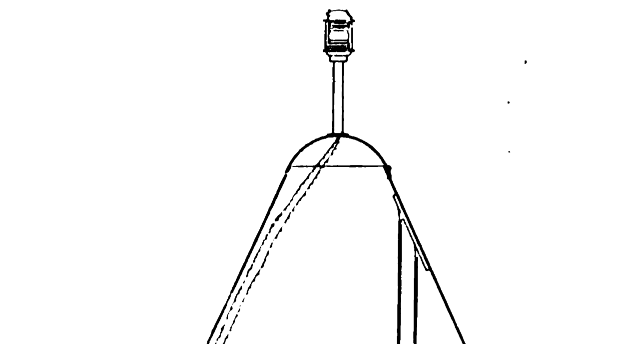
A READER of The Electrical Engineer in Pennsylvania writes us: "Thanks for the sample copy of the paper, but I have been taking it regularly for the past year through my newsdealer. Without any desire to flatter, I consider it the best electrical paper published, and settled down to it as a favorite after a thorough trial of all the others."

*Mr. Horatio A. Foster was employed by the Electrical Engineer to report on an inquiry into municipal electric lighting, undertaken by that journal. His report is published in the issue of September 5, 1894. Mr. Foster is an electrical expert and accountant of high standing, who was employed on the census of 1890, and his report is undoubtedly the ablest and most candid of all the investigations made from the standpoint of those who defend private companies. Prof. Frank Parsons, the results of whose extensive investigations were published in the "Arena" during the latter half of 1895, gives the most painstaking and exhaustive statistical analysis of electric lighting yet made from the standpoint of those who favor municipal operation. While these two writers reach apparently opposite conclusions regarding the cost of municipal enterprise compared with private enterprise, yet their differences are found not so much in the labor cost per arc light as given in Table I. as in their estimates on interest and depreciation. The actual operating expenses, including wages, fuel, stores and supplies, are matters of record stated by the local officials themselves in their annual reports, together with the total unmber of lights operated during the year. Therefore but little variation could occur in computing the labor cost, as will be seen by noting the cases where the two happen to give figures on the same plant. I give herewith all the cities which either one reports. Mr. Foster does not state the cost per year, but he states the cost per lamp hour ond the number of hours per year, and I have computed the cost per year: Mr. Parsons gives only labor cost per year, and not the cost per hour or number of hours. In using these figures, extreme cases should be excluded, as Arlington, Minnesota, and Chehalis, Washington, given by Mr. Foster. In the former there were but four arcs and 100 incandescent lights, and in the latter there were the extra high wages of the Pacific Coast. Where I have been able to examine personally a municipal plant or have made estimates from the annual reports I have so indicated.

MECHANICAL

Fletcher Wave-Power Electric Buoy.

IN our issue dated November 25, 1897, we placed before our readers the details of a wave motor, the invention of Mr. B. Morley Fletcher, Assoc. M. Inst. C. E. We also described tests with this motor in connection with the dismantled barque "Wendla" off Dover, and gave a detailed account of the very encouraging result of these tests. During the recent gales experienced around the coasts of England, we regret to record, the "Wendla" became a victim to the severity of the weather and heavy seas, and was blown from her moorings and stranded on the rocks to the eastward of Dover. The whole of the plant and gear of the various wave motors then on board was, by prompt action, rescued from the wreck, and fortunately the stranding was not attended by the loss of the lives of any of the crew. This catastrophe is the second of its kind that has occurred during the progress of this invention since its inception, and has proved to be a most serious blow to the promoters of the syndicate, but, nothing daunted, Mr. Morley Fletcher, is again quickly to the front with a still further development of his invention in the form of a beacon light, and launch charging buoy, which we now propose to describe.



FLETCHER WAVE POWER ELECTRIC BUOY.

The beacon light buoy is a plain pear-shaped buoy of the ordinary type, as shown in the accompanying illustration, and resembles in form the gas buoy usually adopted by the Trinity Brethren, of which type of buoy there are probably some thousands distributed around the coast lines. The buoy we now illustrate is so designed and arranged as to contain within it the whole installation of the pump, together with the necessary suction and delivery valves, air vessel, turbine, dynamo, etc.; and differs in this respect from the larger power plant previously described in the former issues of this journal, which had its pumping arrangements below the buoy, and a hose connecting the delivery to the attendant vessel, or power station, in order to drive turbines or dynamos. Thus we have in the beacon light buoy, a floating buoy containing a complete installation, fully protected, and furnished with an electric lantern of any desired candle power or brilliancy, fitted in a position well above the surface of the water.

The ordinary gas buoy of the Trinity type is furnished with a light of some 50 candle power, and with respect to its construction, is of a costly character. Apart from this, the upkeep is also very great, as it becomes necessary that a specially constructed launch, or similar vessel, with all its attendant expense of crew, equipment, and the like, should visit the buoy say once in three weeks or once a month at the most, in order to recharge the gas chamber. On the other hand, the latest device of Mr. Morley Fletcher's beacon light buoy, when working at its very lowest power in practically a dead calm sea, may be so designed as to produce electrically a much more powerful light at the head of the lantern than that obtainable from a gas buoy and at a greatly reduced cost. The electrical light may, moreover, if and when desired, be so arranged to flash or glow as required, or be projected through a colored lens in any manner required.

The same buoy may also be fitted to blow a fog horn, or syren; or it may be further utilized for charging an electric launch, or for pumping a column of water delivered at a pressure equivalent to about 600 feet head. The illustration shows diagrammatically an apparatus about to be constructed to the order of The Morley Fletcher-Wave Power System Syndicate, the owners of the British rights in this interesting invention.

The following is a general description of the apparatus: A is the hydrometer tube or spindle of the comparatively stationary portion of the motor, the principles of which we have described at length in former issues. The buoy itself is free to oscillate or move, by the action of the waves, around or upon the spindle. At the top of the spindle, a strong bracket and cross head is fitted, which is connected to the piston rod of the pump B. The pump shown in the illustration is a double acting pump, complete with the necessary suction valves, strainers, and delivery valves. The pump is connected with the receiver or air vessel C, from whence delivery is effected to the turbine or Pelton wheel D, indicated on the diagram, and is coupled with the dynamo E, this in its turn being fixed to a raised circular bulkhead within the buoy. Beneath this bulkhead a large air chamber F is constructed, which is of sufficient cubical capacity to float the whole gear, and thus preserve the buoyancy of the apparatus in the event of water entering the main portion of the buoy by reason of accidental damage or other causes. The illustration shows the particulars and proportions of a buoy rather more than 6 feet in diameter, the details of the machinery being arranged mainly for the purposes of practical illustration. We may also add that the air vessel C has not up to the present been found to be absolutely essential to the plant, and may be regarded as being more or less as an auxiliary to it.

It will be noted that the pump B is so arranged that by shutting off the sluice valve shown at its foot, all connection with the sea may be stopped in the event of it becoming necessary to repair the pump, or even to replace it at sea; or in fact should it be necessary to stop work for any other purpose. This particular buoy is also so designed that, with a minimum of wave movement, it is capable of producing a strong beacon light far more powerful than any illumination obtainable by means of a gas chamber, as the minimum energy developed is about 5 h. p., whereas if the wave movement lifts the buoy through its full stroke fully five times this amount of energy may be generated. It may be asked, what becomes of this surplus energy if 5 h. p. is sufficient to maintain an efficient illumination? The answer is simple; the power is developed, as it were, without extra charge or cost, and the amount wasted is not required, as a bypass containing a relief valve is shown in the illustration through which the surplus water is permitted to escape freely. The pressure at which the water is delivered is determined by the weight of the buoy (which rises and falls by the action of the waves) and the piston area, the dimensions of which are governed

by the desire of a low or high pressure at the delivery. The height of the wave does not affect this pressure, but merely determines the length of stroke of the pump, and the corresponding quantity of water which it forces forward through the pipes fitted for driving the turbine, or for performing other work.

Mr. Morley Fletcher has, during the last few months, added many ingenious improvements to the motor, to one of which we referred in our issue dated November 25 last, whereby an adjustment may be effected, at the water level of the hydrometer tube, by means of an arrangement of a telescopic adjustment cylinder fitted at the bottom end of the tube. There are also certain other detailed improvements which we are not at liberty at present to describe, or to show on the diagrammatical view of the buoy,

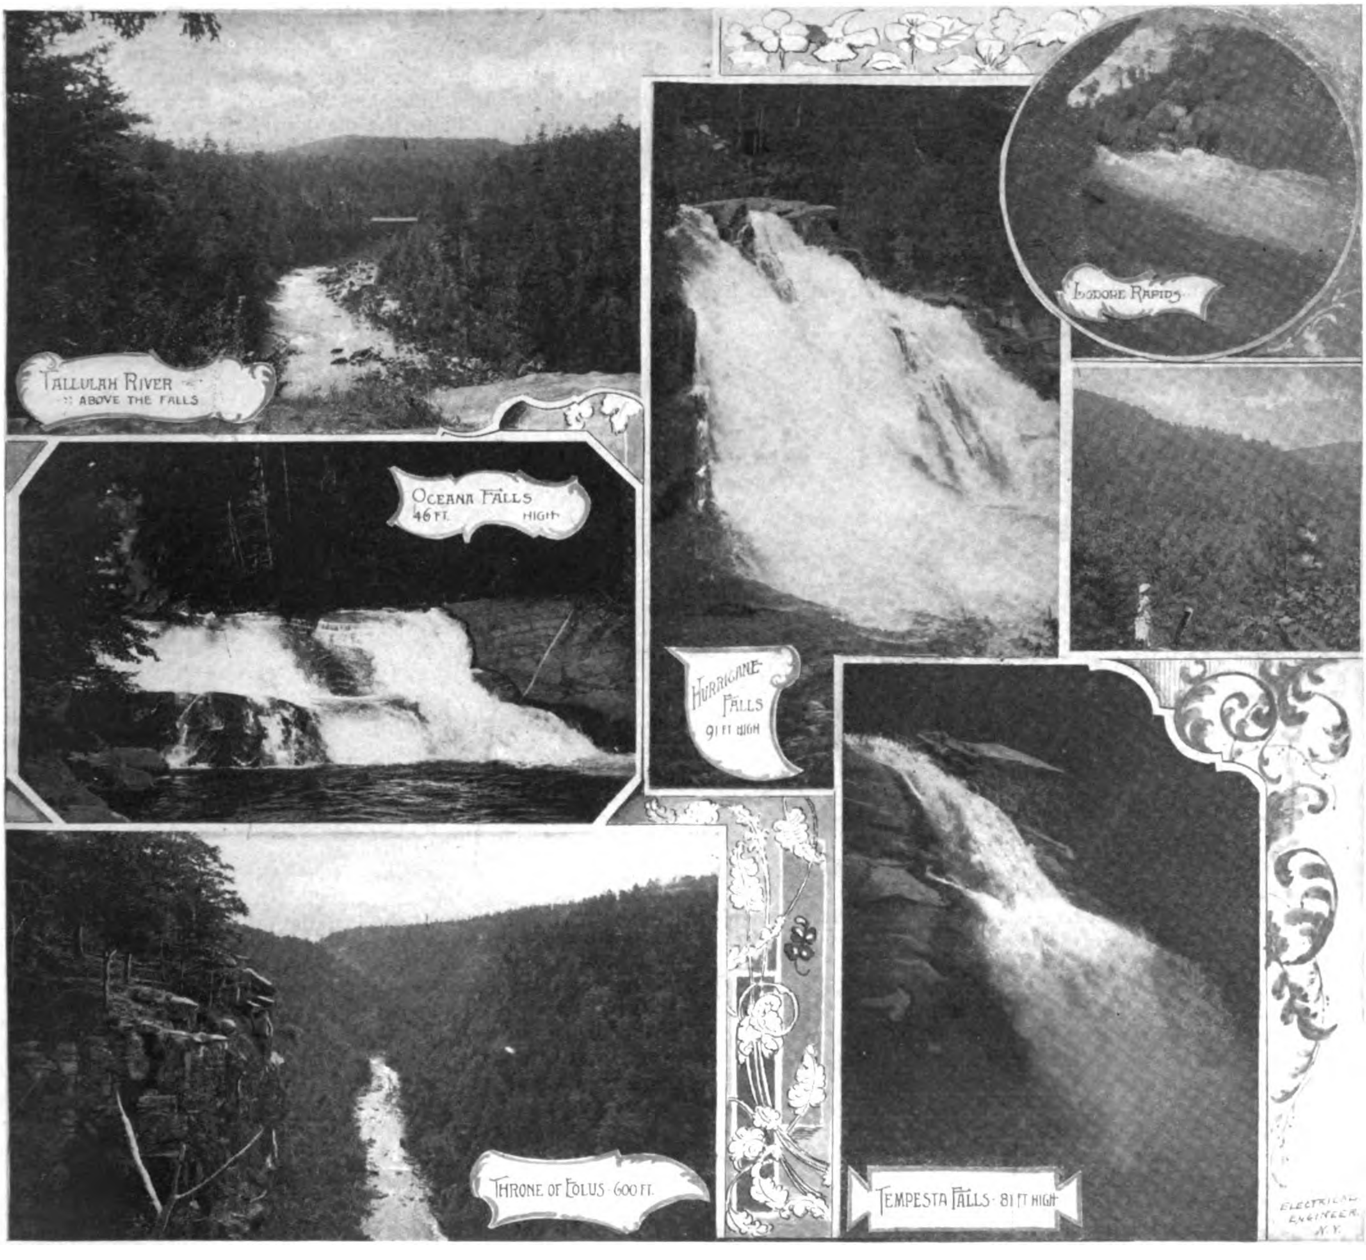
Terminals are provided at the side of the buoy in order that an electrical launch may be moored thereto, and thus receive its charge of electrical energy when desired, thus exploiting an entirely new departure in electric launch work—in fact, the one desideratum the electrical engineer has hoped to procure at sea, viz., an electric current. Means are also provided for ready access, above the surface of the water, to the interior of the buoy, in order that the machinery may be examined, adjusted, and cleaned when necessary, but these are not shown in the illustration, nor are the arrangements whereby the whole of the lower gear, hydrometer tube, submerged resistances, etc., may be raised in order that the whole may be hoisted on board a tug boat or other vessel and easily handled for conveyance to another part of the coast for beacon light or other work. We are indebted to "Industries and Iron" for the above details and illustration.

POWER TRANSMISSION

Utilising Tallulah Falls.—The Niagara of the South.

BY ROWLAND LEE RANDOLPH.

IF there is any one element which determines and promotes industrial advancement it is power at low cost, and no cheaper power can be desired or obtained than that to be derived from waterfalls in our land. Everywhere we find them, some of sufficient size to supply energy to entire cities and towns, others large enough only to furnish power to a single factory or mill.



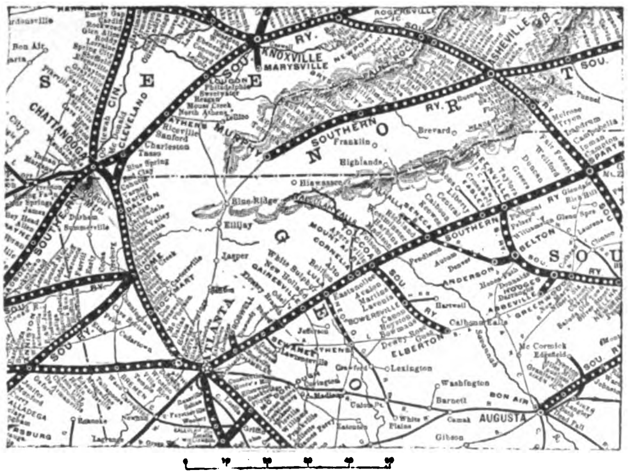
TALLULAH FALLS—THE NIAGARA OF THE SOUTH.

But to rival Niagara, to even adopt this name, means power, beauty and usefulness. All of these requisites are possessed in a marked degree by the Tallulah Falls, so fitly called "The Niagara of the South."

The Tallulah River, which derives its name from the Indian word signifying "Terrible," takes its rise in the mountains of Northeast Georgia, and running through a series of gorges finally finds its way to the Savannah River, of which it is a tributary. The falls of the Tallulah are located about eight or ten miles above its junction with the Savannah, on the dividing line between Rabun and Habersham Counties. The Blue Ridge & Atlantic Railroad, connecting with the Southern Railway at Cornelia, seventy-eight miles north of Atlanta has its terminus at the present at Tallulah Falls, a run of twenty miles. This will soon be continued to Franklin, N. C., shown on the accompanying map, and finally to Knoxville, passing through Rabun Gap, the natural gateway of the Blue Ridge.

As will be seen, the falls are located about equidistant from the large cities of Atlanta, Augusta, Asheville, Knoxville, Sparta and Chattanooga, and to give an idea of the relation of the falls with the Gulf and the Atlantic Ocean the following story may be of interest. Many years ago a government reconnaissance was made of this section for the locating of the Charleston & Cincinnati Railroad. As the party halted on the divide the chief dipped a cup of water from the mountain spring nearby, and drinking, said: "Gentlemen, I pledge you in the waters that flow to the Atlantic," then walking a few steps and filling his cup from another spring, "and now in the waters that flow to the Gulf."

For two miles above the falls proper, the river is a succession of rapids, and the falls themselves, five in number, range from 30 to 100 feet in height. The river banks, which at the uppermost rapids were nearly level with the water, tower to cliffs approaching a thousand feet by the time the last fall is reached. The current is swift; its velocity by a rough estimate, 200 feet per minute. The supply of water is unfailing, as beside its tributaries, the river is fed by many springs.



MAP SHOWING THE LOCATION OF TALLULAH FALLS.

The country in the immediate vicinity of the falls is rugged, promising gold and iron ores, as well as a variety of stone fit for building purposes. Higher up the river, and in the valleys opening from it, the soil is good, and capable of yielding abundant and varied crops. Fruits of all sorts, grapes especially, are easily produced and are of excellent quality. Stock of all kinds can be raised at small expense, requiring little protection in winter, and the miles of untouched woodland furnishing them ample pasture. The sheep are remarkable for the fine quality of their wool, and the delicate flavor of the meat. The hams cured from the hogs of this section rival the celebrated Westphalia. From the extensive forests lumber is to be procured. Springs of the purest water, and also mineral springs, are numerous. The region of the Tallulah Falls, in a word, presents all the requisites and facilities for a great manufacturing center, and can support a large population.

The scenery of the Tallulah Falls is grand and romantic beyond description. From favorite points of view may be seen, in the foreground, the deep and terrible chasm of the falls, with the eagle floating far below; and beyond, stretching out for miles, an ocean of beautiful country. The climate, even in summer, is of an invigorating and bracing quality, and for years Tallulah has been the resort of the health-seeker as well as of the lover of nature in her sublimest moods.

Since the completion of the railroad to Tallulah Falls a small town has sprung up. There are several hotels, three or four stores, a post office, and on the higher points about the settlement some pretty villas, which in summer are occupied by their city owners.

Although no definite figures can be given regarding the depth and width of the stream, on account of no accurate surveys having been undertaken, it can be authoritatively stated that the minimum depth of the river is over 15 feet at any time of the year. An idea of the power can be gained from the above illustrations, which show the comparative widths and heights of the falls and rapids. It is expected that this unused and unusually large and well situated water power will soon be harnessed and used for the numerous new industries which are continually being inaugurated and developed in the surrounding country and nearby cities, as well as for railroad work in this region and for mining operations.

Further Extension of the Niagara Power House.

THE interior of the central station of the Niagara Falls Power Co., is now the scene of great activity, men being at work installing the new turbines and Westinghouse generators which it is intended to add to the plant in order to increase the capacity from 15,000 h. p. to 50,000 h. p. The partition between the old and the new sections has been removed and the two parts of the dynamo room thrown into one. In the picture herewith presented the addition to the dynamo room may be seen by the dark girder to the left over the windows, the light part being of the original section. Far down at the other end is to be seen the 50-ton electric traveling crane used to raise and lower the heavy parts of the installation into place, while in the foreground are the three dynamos now in operation. The floor of the station, in the picture, is well covered with boxes and packages containing parts of the new installation, but when all is in place the dynamo room will return to the orderly state for which it is noted and for which it has been so much admired by visitors. It will not be very long now before dynamo No. 4 is in operation, thus giving the power company an additional 5,000 h. p. to meet the heavy demand made on them for current.

VIEW OF NIAGARA POWER HOUSE.
(Showing Further Extensions in Progress.)

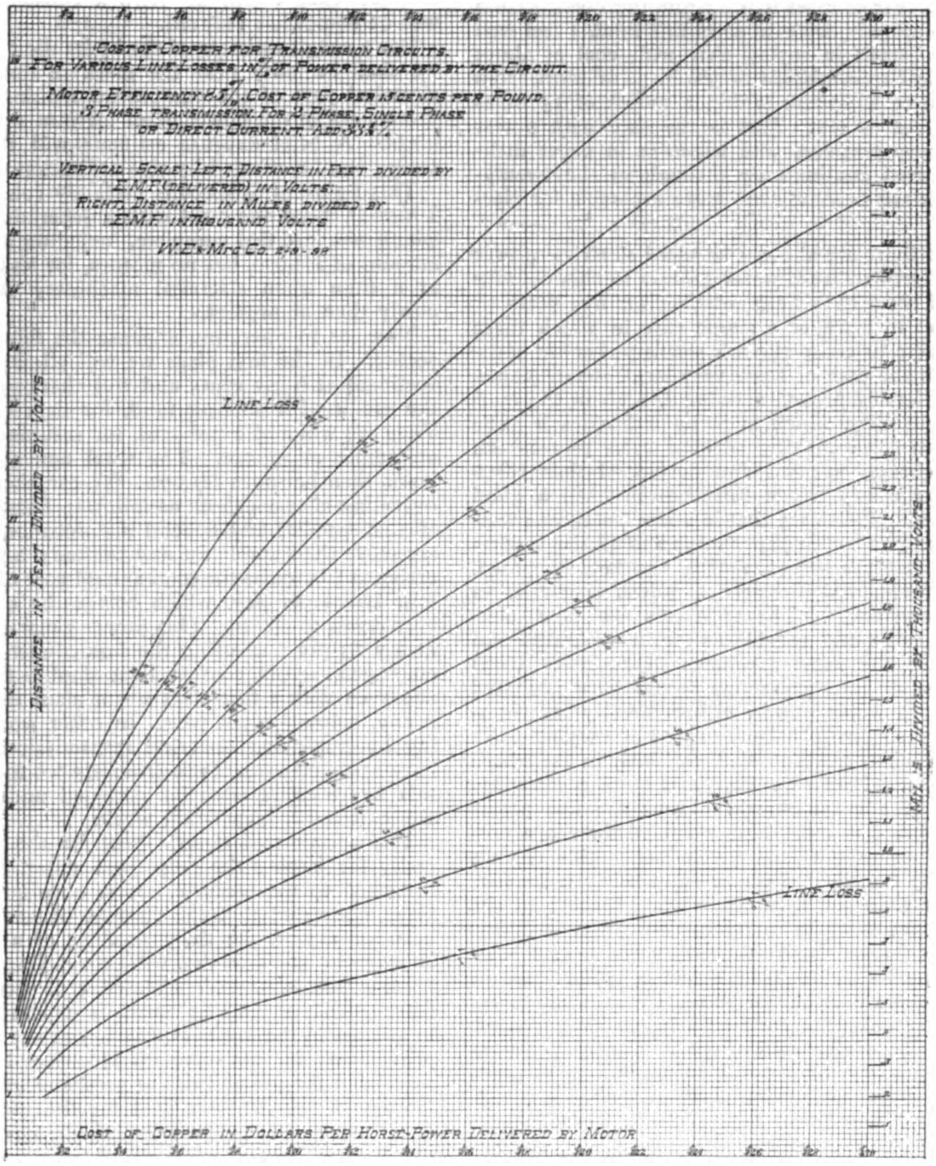
A 108 Mile Transmission.

The one-hundred-and-eight-mile electric transmission plant is again under consideration in Southern California. The undertaking involves the erection of a dam across the Kern River, in Kern County, Cal., and the construction of a line to convey the high tension current to Los Angeles. The Kern River drains an area of some 2,345 square miles, and a total of about 12,000 horse-power can be obtained. A pressure of 30,000 volts is proposed for transmission. While this is exceptionally high,

the dry atmosphere and infrequent rainfalls warrant its adoption. The dam will form a storage reservoir, with a volume of about 13,721,400,000 gallons or the equivalent of 42,000 acre-feet. Should the project be carried out, it would be by far the longest electric power transmission line in the world.

Curves Showing Cost of Copper for Transmission Circuits.

IN the course of a very interesting and highly instructive lecture on "Electricity in Paper Making," before the American Paper and Pulp Association, Mr. Charles F. Scott, electrical engineer of the Westinghouse Elec. Mfg. Co., presented the curve given below, which is both novel and useful. It enables one to find the cost of copper for transmission circuits with any given percentage of line loss, the distance in feet or miles, and the voltage. The lecture was a very exhaustive résumé of the principles and practice of power transmission, with special reference to the application of electric power to the paper-making industry. The curve is, of course, useful in any branch of the application of electrical power for transmission purposes.



CURVE GIVING COST OF COPPER FOR TRANSMISSION CIRCUITS.

MOBILE SHIP CHANNEL.—Capt. R. D. Evans, chairman of the Lighthouse Board, favors electric lighting for the Mobile Ship Channel, but proposals have been asked for Pintsch gas distribution.

Use of Electric Motors in Paper Making.[1]

BY DR. LOUIS BELL.

NUMEROUS paper mills have to face the dilemma of paying heavy freight bills on their raw material or producing their power by steam where the cost of coal is high. Inasmuch as steam is needed in the process of manufacture it is quite usual to drive part of the plant, particularly the Fourdrinier machines by engines, using the exhaust steam for heating purposes.

Now, at the risk of being accused of "teaching my grandmother to suck eggs," I am going to enter a vigorous protest against this practice. It is most emphatically not true that steam thus obtained is cheaply obtained. It implies in the first place very uneconomical use of the engines, and, in the second place, it virtually amounts to generating steam for heating at a high pressure and reducing this to 8 or 10 pounds by the use of a very expensive reducing valve. It is well within bounds to say that the fuel bill for the power is doubled by thus working the engines non-condensing with considerable back pressure, and the cost of the steam used for the heating is thus really a most unpleasant item. For example, take a plant requiring 10,000 horse-power hours per day, and 50,000 pounds of steam for heating purposes. If worked in the common way there will be required for power not less than 300,000 pounds of steam, de-

[1]Extract from a paper read before the New York meeting of the American Paper and Pulp Association, Feb. 17, 1898.

manding burning, say 20 tons of coal under the boilers. Working condensing the same power can be obtained for about 180,000 pounds of steam, say for 12 tons of coal, while the extra 50,000 pounds of steam for heating call for about 3 tons more, making a total of 15 tons daily. A demand for heating capacity so great as to render the power generation a mere accessory would only show very bad utilization of the heat.

In my opinion the first and greatest use of electrical apparatus in paper making is in supplying cheap motive power from waterfalls, enabling the mills to be located at points favorably situated with respect to cheap raw material and easy shipment of product. These advantages once gained the power can be delivered from the nearest available waterfall at a cost generally lower than the local cost of steam power.

It must be distinctly remembered that power thus transmitted electrically is not at all necessarily cheaper than steam power, but in a very large number of cases it is. From the investigation of probably several hundred propositions of this kind, I feel well within the bounds of truth in saying that with coal at about $3 per ton the electrical transmission of 500 h. p. or more from an average water power anywhere within a radius of 15 miles will pay nine times out of ten. This is the case with power transmitted for ordinary purposes, and when, as in paper making, power is often used continuously throughout the twenty-four hours, the conditions become even more favorable for electric working.

At the present time there are above a hundred electrical power transmission plants operated from water powers in this country alone. A number of them have been working for five years or more, and I have yet to learn of a single case in which these plants have been unable to compete with steam power on satisfactory terms, save in the case of some very large steam plants. Transmission has uniformly proved successful, both in the matter of cost and in reliability, which in many industries is quite as important. And in paper-making regions water powers can generally be more cheaply secured and developed than when they are located near a city which furnishes in itself a good market for power. I am glad to say that in a few instances transmitted power is actually in use in paper mills and all the reports received seem to indicate the success that was to be anticipated. There is nothing experimental in electrical power transmission under ordinary circumstances. The apparatus as now constructed is as manageable and reliable as steam apparatus and may be installed with the same assurance of success. Until within the past three or four years one would have hesitated to advise driving from water power, either directly or indirectly, any machinery requiring uniform speed at varying load. Now, however, water wheel governors are regularly in use which are able to hold the speed with an exactness quite comparable with the governing of a good engine. There are few places where uniformity of speed is more highly valued than in a cotton mill, and there are now a half dozen large mills relying entirely on electrically transmitted power—and using it because it is actually cheaper than steam power, although some of the very best steam practice is to be found in the cotton industry.

I can in no way better emphasize the dollar and cent side of the problem than by making an estimate for a typical case of the kind. Let us assume that one of you has a mill which requires, say, 1,000 h. p. delivered continuously for all purposes. Near the proposed site of the mill there is merely a stream big enough to supply water for general purposes, but 10 miles away is a good water power which can be secured without unreasonable expense. What will be the cost of the power transmission plant necessary to do the work?

To begin at the power house, we must allow, say, 1,000 kilowatts in capacity, with preferably a generator in reserve, say three 500 kilowatt direct-connected machines, if the speed of the wheels will allow. The market price of such machines, complete with station equipments, and wound for 5,000 or 6,000 volts, including installation, will not exceed $10,000 each. It is almost unnecessary to state that for a transmission of this length one of the polyphase systems would always be installed. The present tendency is toward high voltage generators, connected directly to the line for such cases, although low voltage generators with raising transformers can be obtained for not far from the same price. In any event, reducing transformers for 1,000 h. p. would have to be installed at the mill, in large units of which the aggregate cost would not exceed $5,000 to $6,000. The 1,000 h. p. in motors would be needed for driving the various parts of the mill, and assuming units of 100 h. p. or more the probable cost of these motors would be $15,000 to $20,000, depending somewhat on the size and speed of the various units. This completes the necessary electrical machinery. The line, assuming say 6,000 volts delivered and 10 or 12 per cent. drop, could be erected with all copper up for less than $20,000. Altogether, the machines at both ends of the line and the line itself could be installed, including a suitable station, for about $80,000; under favorable conditions for somewhat less.

The cost of the water privilege and the necessary hydraulic work is the most uncertain factor in working out any assumed case of power transmission. It may fall even to $25 or $30 per horse-power, and it may rise to $150 or $200. Taking the general average of powers in regions where they have not yet acquired an artificial value by proximity to towns, one may say without being widely astray that $75 per horse-power will cover the necessary expense. With a considerable head this figure will be somewhat reduced.

For a rough estimate of the hydraulic cost in the case in hand, we shall be fairly near the mark in doubling the cost of the electrical part of the equipment, making $160,000 as the total investment in the power plant for furnishing 1,000 h. p. day and night. A brief expense estimate will show how important a saving can be effected by this utilization of electric power.

This figure of $160,000 is certainly conservative enough, since I have in mind one plant with a generating station of 1,000 h. p. which was installed complete, including distribution lines to the amount of $15,000, but no motors, for less than $125,000 and this at a time when electrical machinery was considerably more costly than at present.

Now, as to operating expense the figures are not difficult to secure. In the first place we will allow for interest on the investment at 6 per cent., and will charge annually 4 per cent. to the credit of a sinking fund, for depreciation or replacement. Then we will add 2 per cent. for insurance and taxes—certainly an ample allowance. The total annual charge due to these items then becomes $21,600. We can then make up the regular operating charges about as follows: Labor, eight men and team, $6,500; supplies and general maintenance, $5,000. These figures are more than ample for any ordinary case. Summing them we arrive at $33,100 as the total annual cost of 1,000 h. p. for twenty-four hours per day, which brings the charge per horse-power year down to $33.10. This power generated by steam, with coal at say $3 per ton, using the non-condensing engines too often employed, would cost at least double the amount mentioned, and even with a first-class steam plant the cost would fall little, if any, below $50 per year. In other words, the net yearly saving by employing electrical transmission in such a case as we have assumed amounts to from $15,000 to $30,000 per year. And this figure could often be exceeded under the conditions actually existing in paper-mill work.

The question of electric heat for the drying rolls, and generally for freeing the pulp from water, has been several times broached to me recently, It is only fair to say right now to those interested that the amount of power required to furnish heat for drying the daily product of a modern paper mill is enough to stagger the wildest-eyed and longest-haired electrical crank who ever claimed that electricity was in its infancy. That drying by steam is expensive is painfully evident to anyone in the business, but if you are minded to seek for improvements do not take up electrical heating until you have exhausted the possibilities of producer gas.

To sum up, the best field for the use of electric motors in paper manufacture is in reducing the cost of power, by utilizing the now well-tried methods of power transmission. By this means a mill can be located so as to obtain its material and ship its product economically, without foregoing the advantages of cheap water power. With the transmitted energy at hand, power can be economized by the skilful use of motors in its distribution. There is no cut and dried rule or formula by which the best equipment can be at once determined. Each case has to be considered on its merits, and by the light of common sense, for in the last resort the best equipment is the one which enables you to turn out a given grade of paper at the lowest price.

GERMAN ELECTRICAL STANDARDS.—The "Frankfurter Zeitung" announces that, during the present session of the Reichstag, the draft of a bill regulating electrical standards will be presented for consideration.

LITERATURE

PRACTICAL CALCULATION OF DYNAMO ELECTRIC MACHINES. By Alfred E. Wiener, E. E., M. E. New York, 1898. The W. J. Johnston Company. 683 pp. 6 x 9 inches. Cloth. Price, $2.50.

To criticise a book that gives evidence of so large an amount of labor, applied in so painstaking a manner, is a very unwelcome task. The book is evidently intended for that large class of young men that is making strenuous efforts to learn how to design, in the hope of improved positions and a better class of work; hence, to allow a work so full of errors, misconceptions, and false methods to go to these men, in most cases unable to differentiate the incorrect from the correct, without disclosing its defects, would be almost a crime.

Its author appears to have collected a heterogeneous mass of data from all available sources, and then tabulated the results, without having stopped to discriminate between the good and the bad. This raw, undigested mass he has thrown into book form, with a few connecting reflections of his own, many of the latter showing a misconception of the principles involved. This he has offered to the public with an assumption of authority likely to give those not conversant with the subject the idea that he is master of it.

The very title itself is misleading, since it includes much more than is treated of in the book, wherein only direct current dynamos and motors are discussed, defining thus only a small part of the field included in the title. Many general statements are made without qualification that can, in fact, be applied only to one of the classes of machinery treated; for instance, the first paragraph on page 34, which applies to smooth core machines alone; incidentally, it is incorrect for them also.

The method of design recommended is empirical, and is based on given tables, furnished by the author, as having been tabulated from the data of a large number of machines. Most of these tables, so far as I have examined them, are more or less inaccurate. For example, those on pages 52 and 54 are not in accordance with the best modern practice. Table VI., page 54, is especially impracticable, inasmuch as densities do not increase with the size in regular gradation as there shown; furthermore, the densities in many cases are much higher than is therein stated.

The length of inductor, which is the first part of the design settled on, is determined by these tables and their inaccuracy accordingly renders the whole design uncertain. The length of inductor should not be based on such tables in any case, but is dependent on considerations of armature reaction, heating and sparking limit and economy of design. Many other incorrect laws, tables, and statements might be cited, but space and time do not permit me to point them out. I will mention only one or two of the most obvious, taking them at random.

The law stated on the first page of Chapter III., in the fourth paragraph, should not include the length and cutting speed of the conductor, since the e. m. f. is proportional to the number of lines of force cut in a unit of time entirely independently of the length and cutting speed.

On page 35, second paragraph: "The extra bars are properly cross-connected to the active bars." Such bars are generally not cross-connected, and, in any case, they are all active, and none of them is extra. Nearly the whole of paragraph 18, page 53, is incorrect.

As to the last paragraph on page 30, commutation has no effect whatever on magneto-motive force, and if the lead required for reversal is meant, instead of commutation, the effect on the magneto-motive force of generators and motors is exactly the opposite of that stated. The statement at the bottom of the page, beginning: "Iron is very sensitive to slight increases of magneto-motive force," is not true.

Enough, however, has been said to show that the book is wholly unsuitable for students by reason of its errors and false methods. There doubtless may be much that is valuable in the book, but the busy man has not time to test the data given, and, on the other hand, the student has not the necessary knowledge and experience. As to printing, plates, and binding, the book is well gotten up. THORBURN REID.

STANDARD WIRING FOR ELECTRIC LIGHT AND POWER. By H. Cushing, Jr., electrical inspector for the Fire Underwriters' Tariff Association, of New York. Published by the author. 116 pp., 30 illustrations. Flexible leather. Price, $1.00.

The 1898 edition of this handbook has been completely revised to date and contains the National Electrical Code explained and illustrated with new engravings, illustrating the safest and best methods of installing dynamos, motors and all styles of inside and outside wiring for light and power. One of the most attractive features of the book is its simplicity and clearness of wording, together with its numerous wiring tables for ascertaining just what size of wire should be used for any class of wiring without having to resort to any calculation whatever or to the use of formulæ. This work is now regarded as among the authorities for safe and economical wiring and should recommend itself to electrical engineers, central station men and contractors throughout the country.

MUNICIPAL OWNERSHIP VS. PRIVATE CORPORATIONS. By M. J. Francisco, Rutland, Vt. M. J. Francisco & Son. Paper, 150 pp. Price, 50 cents.

This is the fifth edition of a remarkably interesting book. The author's attitude as a defiant opponent of municipal ownership is well known, for he goes the full length of his feelings and convictions. He gives plenty of reasons, however, for the faith that is in him, and presents a most formidable array of data, as well as many records of municipal plant failure. The book is one which can often be distributed with useful results.

ALGEBRA MADE EASY. By Edwin J. Houston, Ph. D., and Arthur E. Kennelly, Sc.D. Published by the American Technical Book Co. New York, 1898. Price, 75 cents.

The title of this little volume may be somewhat misleading, in that it is not a general treatise on algebra, but has rather a special mission to perform, and contains besides algebraic instruction, chapters on trigonometry and differential and integral calculus. The book has been prepared for the purpose of elucidating the mathematical formulæ appearing in the pages of Prof. S. P. Thompson's "Dynamo Electric Machinery" and "Polyphase Electrical Currents." We believe that the authors have succeeded in presenting the matter in such form as to enable a non-mathematical reader to read the two books intelligently. It only seems a pity that it is necessary to compile such a key to books which contain topics of such vital interest to all electrical engineers as those named above.

HOW TO BECOME AN ELECTRICAL ENGINEER. The Electrical Review Publishing Co., New York. Pamphlet size. Price, 25 cents.

This little brochure is a reprint of a series of prize essays contributed to the columns of our esteemed contemporary, "The Electrical Review." The ideas embodied in these essays ought to be of great value to aspiring electrical engineers, and the suggestions as to the proper course to pursue may save much time and trouble. Appended to the essays is a list of colleges in the United States giving electrical engineering courses.

ELECTRICITY AT THE COLUMBIAN EXPOSITION. By John P. Barrett, chief of the Department of Electricity. R. R. Donnelly & Sons Company, publishers. Chicago, 1894. Price, bound in cloth, $1.00.

This book contains eigthy-four handsome full page illustrations, sixteen of which show exterior views of the buildings at night. The brilliant illumination of the buildings by both incandescent and arc lights made it not only possible to photograph them after nightfall, but also gave unique and artistic results. Seventeen of the full page illustrations are general views giving pictures of the fountains and statuary and there are also fifty full page pictures of the various exhibits. The paper used in this book is finely finished enamelled book paper which allows for the best effect in printing illustrations. The text is generally descriptive of the various exhibits and of the buildings and also contains several reports on the expenses and the operation of the intramural railway, and several short historical introductions to the descriptions of the various departments of electricity. The Western Electric Company has bought up the entire edition left on hand, and is now disposing of it at the above price.

[Entered as second-class matter at the New York Post Office, April 9, 1888.]

Vol. XXV. NEW YORK, MARCH 3, 1898. No. 513.

The Use of the Electric Motor in Paper Making.

A VERY interesting and timely series of papers was read before the American Paper and Pulp Association at their annual meeting held in New York, February 16 and 17, 1898. They dealt with the use of the electric current in paper making and in pulp manufacture, and presented many novel and useful phases of the subject. Steam, water and electric power were compared by men of competence and experience in a broad-minded and unbiased manner, and the papers by Drs. Bell and Emery and Mr. Scott constitute by themselves a complete treatise on the use of electricity in the above-mentioned arts. We present in another part of this issue an abstract of Dr. Louis Bell's very interesting paper on the use of electric motors in paper making, wherein he enters a vigorous protest against the use of exhaust steam for heating purposes in paper manufacturing establishments. He claims that it implies, in the first place, very uneconomical use of the engines and, in the second place, it virtually amounts to generating steam for heating at a high pressure and reducing this to 8 or 10 pounds by the use of a very expensive reducing valve. However, in support of the practice of locating paper mills near waterfalls he says: "In my opinion, the first and greatest use of electrical apparatus in paper making is in supplying cheap motive power from waterfalls, enabling the mills to be located at points favorably situated with respect to cheap raw material and easy shipment of product." Mr. Chas. F. Scott, in his paper on "Electricity in Paper Making," made the astonishing statement that nearly 1,000,000 h. p. is being employed in the manufacture of pulp and paper in the United States and Canada. The common sources of power are waterfalls and steam, both having other functions to perform besides supplying power. Regardless of this fact, however, there is a distinct and useful field for the electric motor, whose adaptability for paper and pulp factories is so apparent that it is rapidly replacing direct power derived from steam and falling water. The machine which cuts the rags in the preparation of rag stock, the slowly rotating boiler in which the rags are cooked, the sawing, barking and cutting wood into chips, the driving of revolving stones, are all operations performed in different processes of paper making which can evidently be operated by electric motors. The quantities of power required vary from a few horse power to several hundred horse power, and there are no exacting requirements as to variation in speed; there is, therefore, nothing novel nor peculiar in the application of electricity to such work. In the paper mill proper power is used from start to finish, and in the larger and best arranged mills must be distributed over a very considerable area, which requires in general heavy shafting, many gears and much belting. Mr. Scott then referred in detail to the advantages in the use of electric motors for these operations and especially to direct-connected motors for the machinery in paper mills, citing in support of his arguments in favor of the use of electric power several large and successful establishments. The plant of S. D. Warren & Company's Cumberland Mills, for example, shows an efficiency of 77 per cent., that is, for every 100 h. p. mechanical output of the turbines the motors deliver 77 h. p. to the machinery at the mills. The alternating current using induction motors seems to be the one most commonly employed. Several interesting tables showing the approximate power required for different pieces of apparatus used in paper mills are included in the discourse, which, after having shown to what uses electricity may be put in the manufacture of paper, concludes by enumerating the uses of paper in the manufacture of electrical apparatus.

Mr. Scott also presented at that meeting the very useful curves for calculating the cost of copper for transmission circuits, which we print on another page of this issue. Certainly no better steam authority could challenge the arguments presented by the above speakers, and expound the economical use of steam in the manufacture of paper, than Dr. Chas. E. Emery. After giving an exhaustive treatise on the generation and utilization of steam, Dr. Emery desired to warn his hearers that "for all ordinary purposes, electricity is a luxury. Still we Americans like luxuries and can afford them;" and regarding the use of the electric current he says: "Local electric transmission has its advantages where the points at which power is to be delivered are widely separated, and it is practicable by means of high tension electric currents to transmit power, for instance, from a waterfall for long distances, utilizing at the end of the line generally more than one-half the power generated. Where water power is cheap and abundant this is desirable, as the annual cost will only be the interest on the installation added to the cost of maintenance. Under other conditions, hold fast to what you already know to be good." To determine this, it is safe to turn to the opinions of those who have made a thorough and exhaustive test of all existing methods and be guided in the selection of a system by the experience gained by these men. One of these is the Hon. Arthur C. Hastings, the general manager of the Cliff Paper Company, at Niagara Falls, who refers to the electrical operation of his plant in the following words: "I believe it would be economy for any new mill to equip itself with a central station for the development of its power electrically and distribute it through the whole plant by motors, thereby saving putting in shafting and belts, and ofttimes losing power through running a great deal of useless shafting, besides saving in other ways, such as oil, fuel and attendance." Altogether the meeting of the Association may be declared a pronounced success and the papers presented of great value to the electrical and paper making industries, for in the words of Dr. Emery, "People must get away from the humdrum of everyday life once in a while, see what others are doing, hear what others have to say, and then determine for themselves as they would for another individual what it is for their best interest to do; and do it."

Victimizing Great Inventors.

ONE of the neatest epigrams ever coined in regard to a newspaper has been that which says: "When you see it in the 'Sun,' it's so." A complementary but uncomplimentary phrase might well be applied to many other of the daily journals to the effect that "When you see it in the ——, it is not so." The recent war scare is but one example of the manner in which the absurdest lies and wildest exaggerations can be given out to the public as truthful news; and it is creditable to the press in general that such disreputable instances of yellow journalism are few and far between. The enterprise of these sensational papers is their saving virtue, but even their large expenditure of money and men they do not know how to handle to the best advantage.

But it is not alone in "war news" that the worst productions of these papers have lately been seen. The field of new invention is particularly interesting to them, and the personality of a great inventor offers peculiar charms to them as a theme around which to weave imaginative yarns. Of late Mr. Edison and Mr. Tesla have suffered greatly from the efforts made to describe their work in the lurid columns of the Sunday issues; and the effect of seeing a thing in print is such that we have no doubt both of these inventors have suffered in the estimation of the respectable public from the manner in which their names have been associated with all kinds of foolish and crazy stories. Sometimes the articles have a genuine interest, but even then the points are made so vaguely, it puzzles people to find out just what the real idea is.

All this might not be so bad, however, but when a man is made responsible for long, "continued" stories, patience is at an end, and thus it was that recently Mr. Edison felt called upon to issue a public denunciation of the use of his name in connection with a fiction running in a New York evening journal and other papers, describing an attack from the earth on the planet Mars. But the story went on appearing all the same. Mr. Edison has always been known among the reporters as an "easy mark," he is so obliging and willing to help them satisfy, if possible, the orders of the city editor; but when his good nature is abused in this fashion he is likely to become less approachable, especially as the liar keeps shifting his energies from one subject to another. Only a week or two ago, a story went around the papers circumstantially as to the remarkable qualities possessed by Mr. Edison's magnetic ore; and an English contemporary has just been sarcastic over it at Mr. Edison's expense. We are now informed that, as was suspected, it is another newspaper lie made out of whole cloth.

An equally flagrant case is that of Dr. Elisha Gray, so well known for his many electrical inventions and the organizing president of the International Electrical Congress of 1893. It has been given out with the fullest circumstantial detail that this distinguished man had gone all to pieces financially, and was in the sorest straits. The public was invited to gloat over his agonizing struggles to keep the wolf from the door. Then as a fine touch it was added that he was dying of it all. The whole thing is a most outrageous lie. It is true that Dr. Gray suffered from the panic of 1893 and the prolonged depression, but that has not been an unusual or exceptional experience, and the Doctor is not "stripped of everything," nor has he been cheated and swindled of every dollar; nor is he living in abject poverty, nor has he had to sell his art treasures, nor is he now taking boarders for a living. Dr. Gray occupies the same house that he has been living in for 26 years at Highland Park, Ill.; he is still surrounded by all his "art treasures," and his library is intact and just as sacred to his own use as it ever was. We believe the "boarders" are his own daughter, her husband, and a grandchild, in whose company and sunshine the Doctor takes natural delight.

The whole miserable story appears to have sprung out of a wish to boom some literary work that Dr. Gray had done upon invitation, for the newspapers, dealing with electrical questions in a series of articles. The "scare head" way to interest the public was to write up, or rather "write down," the author, in a sensational and vulgar style, no matter how indignant he might be or how severely his friends' feelings might be hurt. We have no doubt Dr. Gray has protested vigorously against such abominable methods in the proper quarter; and we now venture to offer our own comments, merely adding in conclusion that one benefit of such annoying episodes must be to help prove to a man that if he is really undergoing trials there are some who will hasten to stand by him.

Welsbach Electric Incandescents.

AN item is going the rounds of the press to the effect that Dr. Welsbach, of Welsbach lamp fame, is now at work on a filament intended for electric incandescent lamps, in which the rare earths of the Welsbach mantle are applied to increase the illuminating power. No details have as yet been made public, nor have the results of any tests been vouchsafed. While we have never been numbered among those who believe that the Welsbach gas lamp can seriously interfere with the progress of the electric incandescent lamp, we are always glad to note any attempted or proposed improvement on the latter, which may enhance its economy. As far as the application of the rare earths to incandescent electric lamps is concerned, the idea has been harbored for a long time and has led to experiments at the hands of several workers. Indeed, we have seen such lamps burning. The economy of these lamps was very high, taking into consideration candle power for energy expended; but their life was uncertain and they developed defects which made their use in practice inadvisable. The lamps being experimental, the cost of manufacture on a large scale was not determined. But even if the cost were higher, the efficiency shown by the lamp would counterbalance an appreciable augmentation in this respect. As to the cost of the rare earths themselves we do not believe that this will stand in the way of their application to electric lamp filaments. The demand created by the Welsbach gas mantle is sufficient proof that these materials can be obtained in commercial quantities at commercial prices. We need hardly point out, in this connection, that the actual cost of manufacture of the present Welsbach mantles bears but a small ratio to their present selling price. Notwithstanding the non-success of the rare earth filaments, which have thus far taken the shape of a deposit on a carbon filament, it does not follow that Dr. Welsbach's new filament labors under like disadvantages; indeed, it is to be hoped that he has successfully solved the problem as to cost and life. The plain carbon filament incandescent lamp has been brought to a high state of perfection, but the limitations of temperature to which it is necessarily subject, must preclude any radical improvement in the future. If, however, without increasing the temperature, or even at a lower temperature, we can act upon other incandescent bodies such as the rare earths, a distinct step forward will have been made.

On Antiquated Data.

WE are printing the reply of Prof. Commons to Mr. R. R. Bowker's article against municipal ownership chiefly because it is right to let both sides be heard. But it seems to us it would be better if Prof. Commons could give the public modern facts instead of antiquated data. It is complimentary to us, of course, to have him quote the Foster statistics compiled for The Electrical Engineer four years ago, but since Mr. Foster is still bringing new material to light, and since other material has been available it would be better to use it. For example, Mr. Francisco's book is now up to its fifth edition, but Prof. Commons hardly appears to be aware of the march of events in this or other respects.

It will be noted that Batavia and Dunkirk, N. Y., again crop up, those moss-grown examples of wonderful cheapness. We would like to direct Prof. Commons' attention to the recent data of Mr. Foster in regard to those two plants, which is unchallenged. The city of Tonawanda, N. Y., on that report has just decided to take service from the local company at $.0195 per lamp per hour, instead of putting in a municipal plant. The wisdom of the taxpayers, voting against municipal ownership about 5 to 1 is shown by the data from wonderful Batavia and Dunkirk, in Mr. Foster's very careful report. They compare thus:

	Per lamp per hour.
Tonawanda (private)	$.0195
Batavia (municipal	$.0204
Dunkirk (municipal)	$.0213
To which may be added:	
Braintree, Mass. (municipal)	$.0455
Danvers, Mass. (municipal)	$.0329
Marblehead, Mass. (municipal)	$.0239
Middleboro, Mass. (municipal)	$.0400
Peabody, Mass. (municipal)	$.0220
Reading, Mass. (municipal)	$.0553
Wakefield, Mass. (municipal)	$.0752

Such data as this, which is all in the more recent records, and official at that, goes to show once again that it is better policy for a municipality to hire service rather than try to supply itself.

Equipping the Brooklyn Elevated.

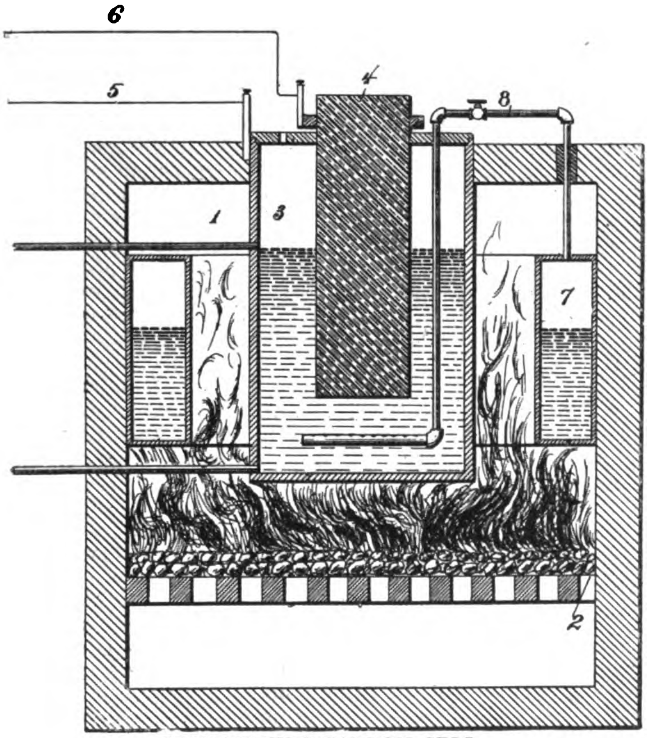
IT must be a source of satisfaction to every electrical engineer to see that at last the elevated roads of Greater New York are to be equipped with electricity. The start is made in Brooklyn, but it begins to look as though nothing would be done in the Borough of Manhattan until change by the chapter of accidents removes the chief obstructionists from power. The foolish nonsense talked by some of the owners of the Manhattan system as to electricity being still in the experimental stage may perhaps be attributed to ignorance. That at least is a charitable view. Meantime the value of the property is relatively, and we think actually running down.

Brooklyn is certainly to be congratulated, and felicitations must also be extended to those who have captured this big initial contract. It is interesting to see the departure made from apparatus of the time-honored locomotive type. Each car is to be equipped with its own motors, and the train can be built up with from one to ten units, indifferently and without regard to end relation. The apparatus has already been put through its paces in Chicago, and the method of control has also been tried there.

MISCELLANEOUS

The Blumenberg Carbon Consuming Cell.

THE problem of transforming potential energy of carbon into electrical energy is one of such universal interest to the electrical engineer of to-day, and the number of competent men engaged in the development of cells and furnaces for accomplishing this result economically and practically, is so large that every improvement, every new device is followed with curiosity and may throw new light on the solution of this great question. A recent process, which we are about to describe, is the invention of Mr. H. Blumenberg, Jr., of New York, for which a patent was granted February 15, 1898. The invention consists of supplying an excess of oxygen to the fused electrolyte by means of superheated steam. In order to hold the oxygen within the electrolyte either chemically or mechanically a fused electrolyte, consisting of lime, cryolite and caustic soda is used which gives excellent results, when they contain oxides or oxygen bearing compounds and steam is injected when it is fused. The position taken or assumed by the metallic oxides or oxygen-bearing compounds seems to be the following: They



BLUMENBERG CARBON CELL.

give up part of their oxygen to the carbon, or, in other words, combine with the carbon, forming carbonic oxide or carbonic dioxide, as the conditions will permit. They then seem to absorb or combine with the oxygen produced from the decomposed steam.

Referring to the figure, the apparatus devised by Mr. Blumenberg consists of a combustion chamber 1, in which there is a grate or burner 2, designed for heating the chamber, and an electrolyte-containing pot 3, perferably of either cast-iron or copper. An anode 4, of carbon or carbonaceous material, is placed in this pot, care being taken that the anode is not in contact with it, to prevent short circuiting. The electrolyte, bath, or conveyer and the oxygen-bearing compound are also placed in the pot. One of the conductors 5 is attached to the pot and the other conductor 6 to the anode 4, preference being had not to introduce the steam until after the conveyer is fused. The steam may be introduced from any suitable generator; but it is preferred to provide a jacket 7 or other suitably shaped reservoir within the combustion chamber 1, in which steam is generated. 8 indicates a steam pipe leading from the jacket 7, preferably into the bottom of the pot 3. The carbon will when heated combine with oxygen, forming carbonic oxide or dioxide, as conditions will permit. The injection of superheated steam to all appearances decomposes into oxygen and hydrogen and at the same time agitates the fused electrolyte, thereby increasing the electrical energy.

As an oxygen-bearing compound the natural ores in lieu of the oxygen-bearing compounds previously referred to have been used. If the temperature of the electrolyte be raised sufficiently, the metals from the ores may be reduced at the same time the electrical energy is produced and at one and the same operation. Care should be taken that the ore does not choke or clog the electrolyte or that the reduced metal will not short circuit the carbon anode with the pot. In this double continuous operation the metal is tapped from the electrolyte at intervals. The superheated injected steam is here continuously introduced after the electrolyte is fused. Of course this is only applicable to such ores as are easily reduced.

In using a hydrate or nitrate of an alkali for a fused bath, electrolyte, or conveyer in which the oxygen-bearing salt is the oxychloride or subchloride of copper, the electrolyte-containing pot should be of copper, because better results are obtained electrically, especially in electromotive force—that is to say, a higher voltage is obtained.

In using the metallic oxides or oxygen-bearing compounds it has been noticed that if enough surface is given by the electrolyte, bath, or conveyer which contains the above named metallic oxides or oxygen-bearing compounds to the air large quantities of oxygen seem to be absorbed from the surrounding atmosphere. This is especially noticeable if copper oxychloride, or subchloride, or barium oxide, or barium hydrate is used. The last named chemical is on heating transformed into the oxide.

The bath electrolyte or conveyer in this case can be preferably an alkaline hydrate or nitrate. A water heating chamber is placed within the furnace and a pipe is led from it into the electrolytic cell, by means of which the furnace is made to generate the superheated steam and force it into the electrolyte.

Whittemore's Coal Solution for Primary Batteries.

THE combinations and mixtures of solutions tried for primary batteries are endless, and new ones are still constantly suggested and applied. The most recent is that of Mr. J. B. Whittemore, of London, who in a recent patent describes the application to primary battery solutions of ordinary coal prepared in a special manner and mixed with water. He also discovered that the specially treated coal has another remarkable property, and that is that when added in a small quantity to the acid solution of an ordinary battery cell it increases the quantity and strength of the current therefrom in such a manner that iron may be used in place of zinc as the positive element in the cell. The cost of treating the coal is insignificant, and as the coal is itself inexpensive, Mr. Whittemore claims that considerable economy will be effected in an ordinary battery by using ordinary water as the liquid of the cell in place of an acid solution and by adding thereto coal which has been treated in the manner described below.

The hard or soft coal is treated in the following manner: A block of convenient shape and size and, say, of about four or five pounds weight is taken, and on the top of this is placed a small piece—say of about ten grains weight—of sulphur, camphor, pitch or of any other inflammable substance which when burned in the open will ignite, and allow it to burn itself out on the top surface of the coal. When the inflammable substance has burned away the block of coal is at once adaptable for use in a water liquid cell or as a means for augmenting the electrical properties of an acid solution cell.

Mr. Whittemore has made and tested three double fluid cells, each having carbon and iron elements, the liquids being water drawn from the ordinary domestic service pipes, to which has been added coal treated in the manner above described. For the first of these cells the coal had been perpared by burning a small piece of sulphur thereon, for the second camphor had been used instead of sulphur, and for the third pitch had been used instead of sulphur or camphor. The coal is preferably added to the cell containing the carbon electrode; but it may be added to both. Each of these cells when kept at a temperature of about 60 degrees Fahrenheit gave, when tested, a current of one volt and 0.5 ampere. The current of the cells is observed to vary. As

much as one ampere at one volt has been obtained. One-half ampere at one volt has been frequently observed, but often no more than one-quarter ampere at three-quarters volt and sometimes less, depending, perhaps, upon the temperature or on the atmospheric influences. The current has been observed to continue in diminishing volume for weeks.

From these results it would seem that the burning of a small quantity of an inflammable substance on coal effects a change of some kind in the molecular structure of the coal, rendering it after such treatment advantageous for use in an electrical battery; but whatever the theoretical effect on the coal may be it is certain that an electrical current of appreciable quantity and strength is produced by the use in a water liquid cell of the coal treated in the manner before described and that no such result is produced when ordinary coal not so treated is added to the water liquid cell. Mr. Whittemore has also tried the effect of the addition of the specially treated coal to an acid solution cell. For this purpose he took an ordinary Bunsen cell of three pint capacity, and to this added about six ounces weight of the specially prepared coal in small pieces to the nitric acid solution, and substituted an iron element for the zinc. When tested, this cell gave substantially the same voltage and ampere measurements as the original Bunsen cell from which it was made.

Questionable Economy of Changing Primary Pressure.

BY BINGHAM HOOD.

WITHIN the past few years there have been a number of stations that have, in order to reduce the line losses, due to increased load that has not been provided for in original construction, changed their primary pressures from 1,000 to 2,000 volts.

Some have taken this step by the advice of competent engineers or through managers, but a large number simply because some similar plant has effected a large saving by the change. Fortunately a large number of this latter class have been able to decrease their running expenses by making the change, but a considerable number have found that, after expending a considerable amount of capital, the saving does not begin to cover the interest on the investment.

There are two questions that will be asked any one suggesting such a change. First, what alterations are necessary, and what will it cost to make them? Second, how much can be saved by making the changes?

Whether the answer to the first question is greater or less than the second, will determine the advisability of making the necessary money outlay. Taking up the first question the necessary changes would be: All converters must be rewound for the higher pressure, or, more practically, replaced by new ones; all switchboard instruments depending on the potential for their operation, must be either altered or new ones substituted, and dynamo armatures must be rewound for increased potential, and, if of compound field type, the field shunts or series converters must be changed in order to keep the compounding factor the same.

Presuming that an accurate record of all converters has been kept, with their respective capacities, the determination of the cost of material is comparatively simple. To this must be added the cost of labor to make the changes. The old converters, unless of very recent type, will be of very little value; probably about sufficient to cover the labor cost of removing them and substituting the new ones. It is well to consider while making a change of this kind, whether or not it is advisable to put in new two-phase machines, and reduce the number of periods of alternation, with a view of obtaining a power load. In small stations, however, it is seldom advisable to attempt running a day service unless the conditions are unusually favorable to obtaining a considerable number of motor customers.

Taking up the second and more complicated question, the first step would be to determine the number of kilowatts expended in the line per year. Some stations keep an accurate record of this amount, but by far the greater number do not. If no record is available, it would be necessary to determine an average by taking the switchboard readings for a few days or weeks, and then approximating this amount for the year.

A very simple way of doing this is to take half-hourly readings of each amperemeter, and the difference of pressure between the switchboard and centers of distribution. If such center is connected by a pressure wire it is only necessary to take readings from the two voltmeters on the board, one connected to pressure wire and the other directly across bus-bars.

If there is no pressure wire, the second voltmeter will necessarily have to be connected directly at the distribution center; readings being taken at pre-determined intervals by an attendant at this point. Just here a word of warning will not be amiss. Do not assume that the voltmeter readings are the true pressures; the readings must be multiplied by the ratio of convertion of the transformer to which they are connected.

After having obtained these readings for a time sufficient to give a fair average record of the load (one full week would probably be sufficient), the product of the amperes and voltage difference of the two points will give the watts expended in the line. It is now necessary to determine the cost of furnishing this amount of power. The running expenses will remain practically the same, with the exception of fuel, and possibly water, if same is purchased by meter. Unless an accurate record of this amount, per unit at switchboard, has been taken, it will be necessary to determine the cost at the same time previous readings were taken. After obtaining this cost per unit, the number of units expended in line must be multiplied by it.

From the well known law we find that if we double the pressure, the same amount of energy can be transmitted with one-fourth the line loss. Therefore, by raising the pressure from 1,000 to 2,000 volts, three-fourths of the energy previously wasted in the line will be saved, thus giving the answer to second question.

Comparison between the result thus obtained and the interest on the cost of making the change will determine at a glance whether it will result in profit or loss. The cost of making the change will be very nearly the same for any two stations of the same size, but the saving may vary greatly; depending entirely on local conditions. For instance, one may have a fairly constant load factor, while the other may have one varying from full load for a few hours to nearly no load for the rest of the running day. Again, one may pay a high price for fuel, while another may obtain it for nearly the cost of mining; or may use water power, in which case the saving would be practically nothing. It is therefore evident that each station must examine the conditions governing its own particular case, and not use data obtained from any other plant, as the saving is directly affected by either of the above stated conditions.

In some cases the line loss can be reduced to the same extent by a judicious application of feeders, with booster converters or regulators at their switchboard end, at a cost not exceeding that necessary to change the system to a higher voltage, thereby saving much of the confusion and inconvenient interruptions of service, unavoidable where a general change of apparatus is carried out.

Acetylene Gas Lamp Factory For Niagara.

A new factory now being built on the property of the Niagara Falls Power Company, at Niagara Falls, is to be used for the manufacture of portable lamps, in which the fuel will be acetylene gas generated from carbide stored in cartridge form in the lamp. When the lamp needs "refilling" all that will be required will be to take out the old cartridge and insert a fresh one. The carbide for charging these cartridges is to be obtained of the Acetylene Light, Heat and Power Company, whose plant is situated close by the new factory, so that there will be no expense of transporting it from one plant to the other. The factory building will be of frame, two stories high and 50 by 110 feet at the foundation. It is being erected by the Electro Gas Company, of New York, for another body of men who will put the experiments and theories of the first-mentioned company into practical use. It is understood that experiments extending over a period of several months have been made in burning acetylene in all styles of lamps, from those used for household purposes to the bicycle and carriage lamp, as well as lanterns, and that the experiments have been so successful that the company are eager to get their plant in working order in order that they may get their wares on the market in great quantities. Gas is well known as a very clean illuminant, but in many cases the owners of buildings have been deterred from using acetylene by the fact that they would have to pipe their houses the same as though they were about to use coal gas. With the use of the portable gas lamp this expense will be saved, and if as successful as predicted, the lamps may come into quite general use.

New Type F Wagner Transformers For Lighting Work.

THE new types of transformers recently placed on the market by the Wagner Electric Manufacturing Company, of St. Louis, are the results of many years of labor in experimenting with transformers and in gaining experience in transformer design. The new transformer illustrated and described below is called the type F transformer and differs from their well known type G only in that it has a slightly lower efficiency. It is intended for night service stations and is specially constructed and recommended for this class of work. Both types of transformers are designed to afford a degree of economy in transformer service in excess of that heretofore possible with transformers built by this or any other company. It furthermore embodies many decided mechanical improvements.

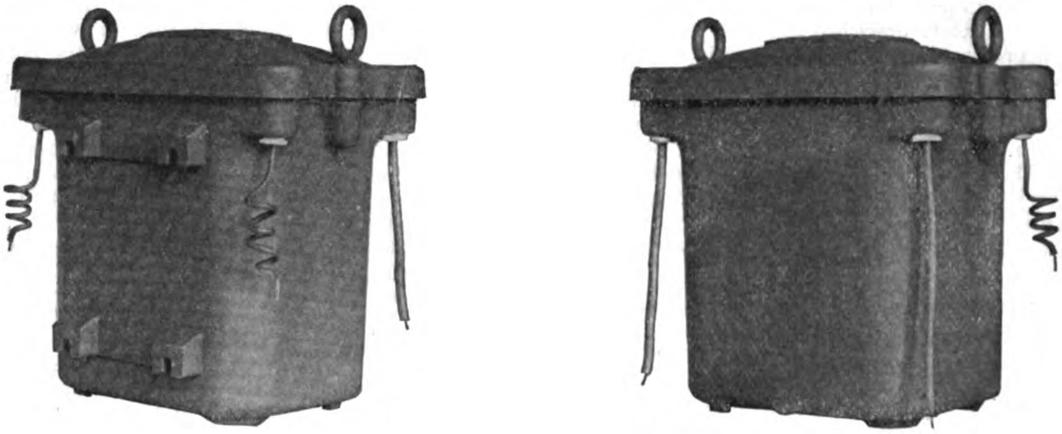


FIG. 1.—WAGNER TYPE F TRANSFORMER WITHOUT FUSE CUT-OUTS.

The general design is clearly shown in the illustrations, but the following special features are worthy of mention: First, the leads, both primary and secondary, are brought out vertically through most substantial porcelain bushings, and are of extra flexible standard cable. The cable used is of the very best high tension quality, and its flexibility greatly facilitates connection to line wire when erecting. The general character of bringing out the leads is such that surface creepage of current to the case is an impossibility. Second, the covers to the cast-iron cases are held down by the eye bolts in place of small screws as heretofore, and a broad lip comes down over the top of the box, assuring the effectual draining off of all water, whatever the atmospheric conditions. Third, the hanger irons are no longer bolted to the cases, but now slip into receptacles cast upon the boxes (see Fig. 3) greatly facilitating erection, from the fact that the lineman requires no tools whatever in the operation. The sizes of hanger irons have furthermore been decreased greatly in number, one size of iron fitting four or five sizes of transformers, where heretofore each size of transformer has required its special size of hanger iron. No improvement in any direction will be more appreciated than this of simplifying the work of erection. Fourth, there are but two secondary leads, instead of four, the connections for 50 or 100 volts being now made on an interchangeable block inside the case instead of by cross connections on the outside, with the single exception of the 500 watt size. In this size the standard is wound invariably for 100 volts, although both 50 and 100 volt ends will be provided where especially ordered. Fifth, two types, one with and the other without attached fuse blocks, are built. The attached fuse block is that form built in independent box form. The fuse is carried in a completely closed tube within a removable porcelain plug. This construction is shown quite well by Fig. 4.

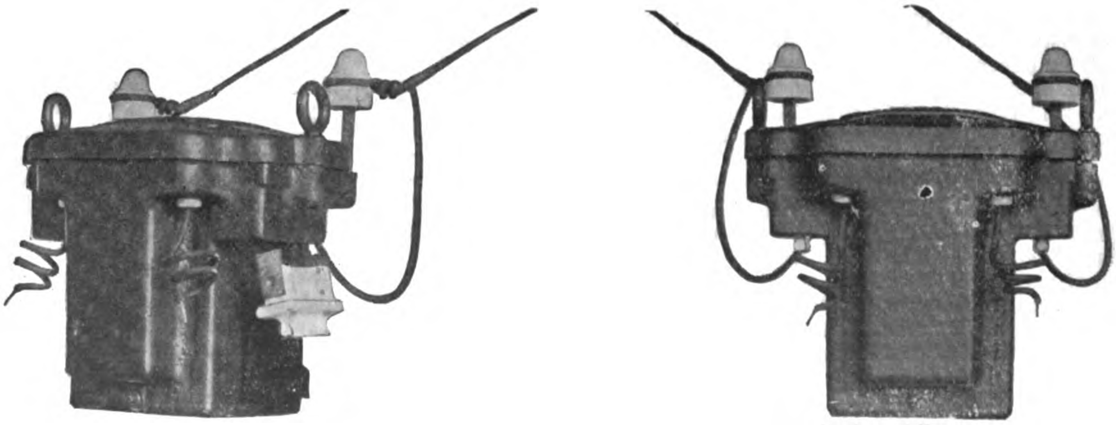

FIG. 2.—WAGNER TYPE F TRANSFORMER WITH ATTACHED FUSE BOXES.

The principal features of the interior construction of the transformer are: First, the coils are placed horizontally so as to increase the safety of the windings. Second, all ends come out without crossing. Third, the transformer proper slips into the case in a new way which provides against mechanical displacement. Fourth, all 2,000 volt transformers, with the exception of the 500 watt size, are provided with an interchangeable device enabling the connections to be easily changed for operation on either 1,000 or 2,000 volts as desired. This same interchangeable principle is employed upon the secondaries, enabling them to be run on either 50 or 100 volts. Small copper links serve the purpose of completing the connections of the transformer coils to the outside leads. Simple changes in position of these permit the change of voltage. Fifth, the type has been designed for use dry or oil filled. Transformers for 1,000 volts may be used in either manner, at the selection of the purchaser. For all 2,000 or higher voltage coils, oil is recommended. No mechanical changes in the cases are necessary to adapt them to either dry or oil service. They are ready for use in either manner when shipped from the factory. The plug seen on the front side of the case, near the bottom, serves merely for the draining out of the oil when it is desired to shift a transformer from one place to another. This opening also remains closed when the transformer is used dry.

Special attention has been paid to the insulation of the transformers, and no better evidence of the thoroughness of the insulation of the windings could be given than in the following specification for testing, which every transformer built must meet:

	Alternating voltage required to withstand Dry.	Oil-filled.
Insulation between primary and secondary..	6,000	10,000
" " primary and case........	6,000	10,000
" " secondary and case......	6,000	10,000

Furthermore, every transformer is guaranteed to safely withstand, as an insulation test, the application to the primary of twice the voltage upon which it is to operate. In other words, 4,000 volts may safely be sent into every 2,000 volt transformer, and no harm will result. Such tests preclude the possibility of a defective transformer leaving the factory.

The exclusion of the air from the windings, the assistance afforded in cooling and the very high insulating value of properly selected oil are its especially valuable qualities. Safeguards in the use of oil are quite essential, however, and for this reason the guarantee on Type F transformers only holds good when oil is furnished by this company. The practice is rigidly followed in the Wagner Co.'s factory of treating and testing by a special process all oil used for transformer purposes. This practice insures a quality of oil that can be depended on, whereas were they to permit the purchase of oil by the customer in the open market there would be no way of knowing anything about the quality of the oil he might secure.

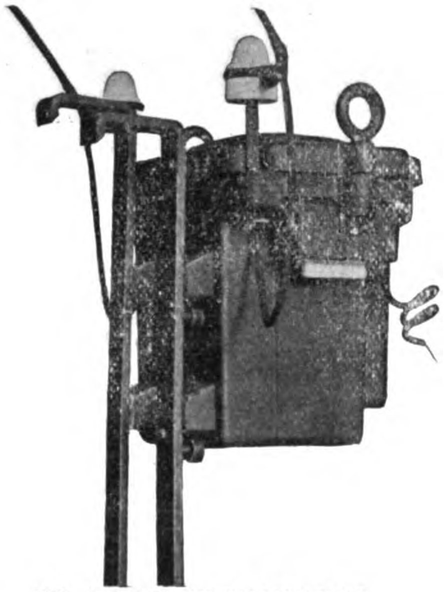

FIG. 3.—METHOD OF HANGING.

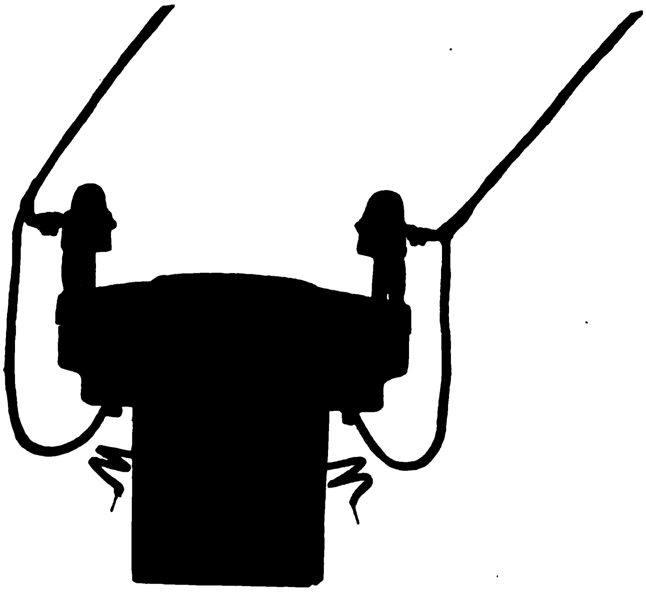

FIG. 4.—FUSE BLOCK WITHDRAWN.

Much has been said of late relative to the "ageing" of the iron in transformers. This phenomenon has been under investigation by the company for several years, conducting many series of tests through that interval to determine the extent of the ageing going on in their transformers. These tests have demonstrated that the ageing taking place in the Wagner apparatus is an almost inappreciable one, guarded against as it is by a most thorough maintenance of those special properties of the material which minimize the effect.

While no good station superintendent makes it a general practice to overload his transformers, nevertheless occasionally circumstances arise making it inevitable to load a specific transformer beyond its rated capacity for a limited period. The Type F transformers can be safely overloaded 25 per cent. for a period of three hours, without incurring damage to the insulation. In some instances, engineers who do not desire to depend on the very high insulation between primary and secondary windings, specify the insertion of a metallic shield for the secondary coils. This shield is grounded to earth, and in case of any puncture of the insulation of the primary winding, all leakage current escapes directly to earth instead of to the secondary coils should their insulation also give way. Where such extra precaution is required, the Type F will be so constructed, the general design adapting itself excellently to this end. Such ground plates are not, however, recommended where their use can be avoided.

Mr. Wagner has always advocated the close testing of all transformers. Every central station should have a record of the performance of its transformers. Such a record can be easily maintained, as the essential tests to be made are such as adapt themselves readily to station conditions and equipments. The instruments required for these tests are those frequently used on other kinds of testing about lighting and power plants, and the time required is relatively small. The most important test is the measurement of the "core" loss, or "leakage" loss. This is the loss constantly going on in the transformer, whether the customer be using current from the secondary mains or not. Next in importance is the "regulation" test. These two tests at once disclose the electrical characteristics of the transformer, and will enable the station man to determine for himself the relative excellence of various makes of transformers offered him. Finally he should test the insulation of each transformer on its receipt from the factory. The instruments required for the core loss test are an indicating wattmeter and a voltmeter. The Wagner Co.'s Type H instruments are admirably adapted to this purpose. For core loss measurements a wattmeter reading up to 300 watts is recommended. For the voltage measurement a voltmeter with scale of from 90 to 120 volts. The method of test is to send into the secondary the rated secondary pressure, leaving the primary ends open. The source of current is usually the ordinary station lighting circuit, providing this is supplied from the generator on which the transformers are to operate or from another machine which generates the same frequency of current. By means of an adjustable rheostat the pressure at the terminals of the transformer under test is brought to exactly the rated amount. The wattmeter will, when connected in circuit according to instructions that are furnished with it, indicate the watts lost. It must be understood that the core loss on any two transformers of the same size is not necessarily the same, and that the results shown by any given transformers are not necessarily indicative of results to be expected from that make in general. Every transformer should be tested for core loss. The regulation test is not so easily made. However, it is not necessary to make it upon every transformer. It is only recommended when the station superintendent desires to compare one make of transformers with another. The three things to be determined are: 1st—The ohmic resistances of the transformer windings. 2d—The voltage necessary to send the full load current through the transformer when the secondary is short circuited. 3d—The "leakage" current in amperes. The ohmic measurements should be made with the Wheatstone bridge or with direct current instruments, employing direct current instruments in preference to the bridge on account of the low resistance of the secondary windings of transformers. The second factor, commonly called "impedence" voltage, calls for an ampere meter in addition to the voltmeter and wattmeter. An instrument reading up to 10 amperes is recommended. The Type H ammeter will serve nicely for this purpose. The third factor can be determined by

dividing the core loss in watts by the factor 65. This is not strictly accurate, but is a sufficiently close approximation for general work.

The Wagner Co. have also placed on the market within the last few months large astatic transformers for high voltage power transmission. They are prepared to construct the apparatus in units of any size required, and for any ratio of voltage transformation desired. Many of these large transformers have already been installed in Western power plants and are giving excellent service.

Temperature Coefficient of Resistivity of Graphite.

BY JOSEPH W. HARRIS.

IN February, 1897, Mr. J. W. Howell read a paper before the American Institute of Electrical Engineers on "The Conductivity of Incandescent Carbon Filaments and of the Space Surrounding Them," in which he gave a curve showing change of temperature coefficient of resistivity of graphite from negative to positive. I wish to call attention to the fact that the temperature at which this change takes place in graphite is not very different from the temperature of recalescence in a high carbon steel, and think that the change in graphite must also be accompanied by a change in its chemical properties, on account of the corresponding change in the properties of steel when suddenly cooled from temperatures above or below the temperature of recalescence.

TELEPHONY AND TELEGRAPHY

The New Electrical Factory of DeVeau & Co.

THE rapid development of telephony in this country and the construction of numerous "independent" exchanges has naturally opened up a large and remunerate field for the manufacture of telephone apparatus and appliances. The older concerns, whose apparatus has been used for years and has been

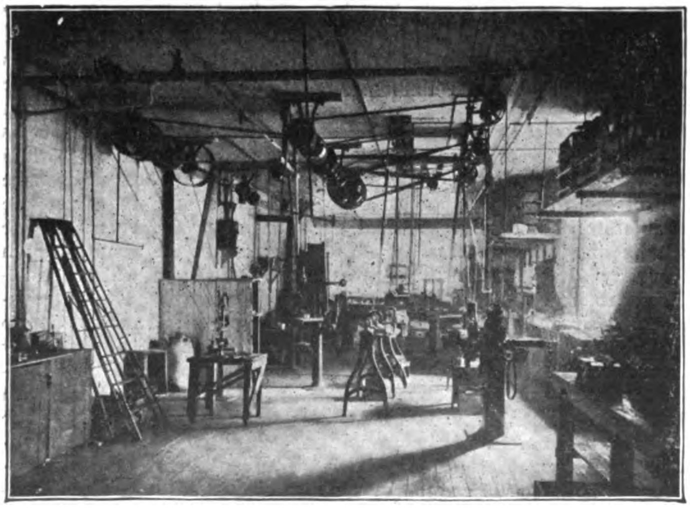

FIG. 1.—NEW MACHINE SHOP OF DE VEAU & CO.

thoroughly tested and constantly improved, are finding a more extended market for their goods and are forced to seek larger quarters. One of the best known manufacturing concerns of telephone and other electrical supplies in the country, De Veau & Company, found their factory inadequate for filling the orders which were constantly increasing in number and size due to the above conditions and have lately moved into very commodious quarters at 27 Rose street, New York City. The factory covering an area of 135 by 250 feet consists of a spacious and well-equipped machine shop, shown in Fig. 1. It contains numerous planers, engine lathes, automatic machines, millers and drill presses. Then there is the assembling room, shown in Fig. 2, where the transmitters, receivers, magnetos, etc., are assembled and tested, the superintendent's desk being shown in the foreground; the inspection department, where every telephone set is thoroughly tested before it is shipped from the factory; the forging depart-

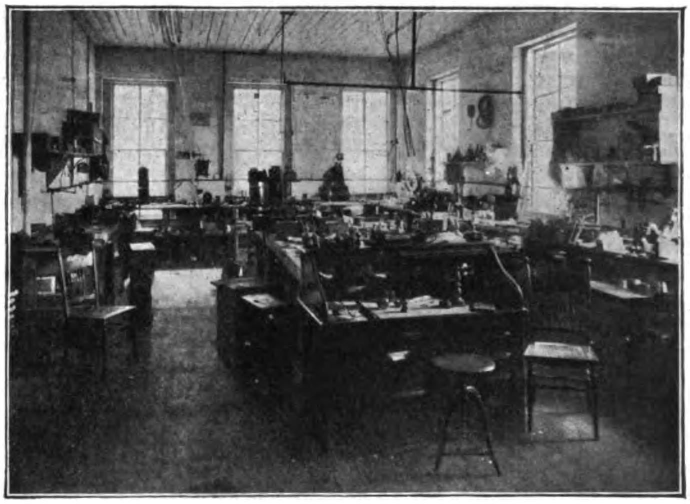

FIG. 2.—ASSEMBLING ROOM IN DE VEAU & CO.'S NEW FACTORY.

ment, where the magnets for the magneto-generators are shaped; the shipping department and the business offices of the executive officers of the company. Over fifty hands are employed in the establishment, which number will probably be increased at an early date.

The goods manufactured by this company, which have frequently been illustrated in The Electrical Engineer, are of the best quality and every small feature receives the most careful attention. Tests are made continually to see whether some detail cannot be improved or whether a change of material will not produce better results. The De Veau transmitter is guaranteed not to pack, nor to get out of adjustment. The packing is prevented by stretching a piece of oiled silk between the mouthpiece and the small contact point, to keep out the moisture. The diaphragm is pressed against the shell by a couple of large flat springs bearing against it in four places. A small canvas receptacle filled with powdered carbon is supported on a delicate spiral spring which serves for the final adjustment of the instrument. This also prevents sticking and is a novel feature in this transmitter. All parts are interchangeable and the best material is used throughout. The coils are silk covered, the magnets in the receivers are shellaced and the binding posts possess admirable features. The magneto-generators have a clear ring. The crank has to be pushed inward before a signal can be given. This enables special calls to be transmitted between private subscribers, which is often a great convenience. The magnetos have specially long switches insuring good contacts and the woodwork on all the apparatus is of very high quality.

The company manufacture long distance telephones, combination sets, intercommunicating telephones, desk and interior telephones, special hand telephones, transmitters, receivers, magnetos, switchboards and telephone supplies of every conceivable variety.

The apparatus of the company has been installed in U. S. Government offices and by numerous large corporations as well as many well known business houses in this city and throughout the country, and export orders are constantly being filled.

The company was formed in 1892, by Mr. A. S. De Veau, and to his indefatigable energy and extensive experience the success of the firm is mainly due. Mr. De Veau was employed by the Western Electric Company and other telephone concerns for over ten years in every conceivable capacity from mechanic in the shop to line constructor and operator, and has mastered the business in every detail. The superintendent of the factory is

Mr. Charles Auth, who has had a long experience in the construction of telephone apparatus.

The company have never had an infringement suit or any legal interference and have won by the merits of their apparatus the confidence of the profession and the general public.

The Budapest Talking Newspaper.

A SMALL diamond-shaped board screwed on to the wall of my room, and provided with a couple of hooks from which hang two tiny, round telephone earpieces connected by two wires. That is all. But my hotel proprietor has been singing its praises for the last twenty minutes, and as he confidentially assured me that it will not play any part in my hotel bill at the end of my stay, there is no earthly reason why I should enter any protest against his profuse encomiums. "This," said he, "is the Telephonic Messenger or talking newspaper—the only thing of its kind in the world. It has now been established in Budapest about three years. It differs from the ordinary telephone in the fact that the latter is directly connected with the central office, whereas we are able to connect from 200 or 300 subscribers in one circuit. The city is divided into thirty circuits. All day long news is spoken into a specially constructed apparatus at the central office, varied with entertainments, the opera and linguistic lessons. It is not a telephone in the strict sense of the word, and therefore, does not infringe the telephonic rights of the government. It combines the functions of your tape machines and electrophones, while it is ten times cheaper. That buzz you heard just now was to prevent subscribers talking to each other on their own account."

"It seems strange that such an excellent idea as this appears to be should not be introduced in other towns than Budapest," I ventured.

"The answer is very simple. Of course, the newspaper feature would be impossible in London, where time is everything, and a man could not sit the whole day with the apparatus to his ear, waiting for some particular news or exchange prices. Then again, other towns are not so advantageously situated in this respect as Budapest, where the law empowers the company to introduce the apparatus into any house in the city in spite of the objections of the landlord. We have here six thousand subscribers, and each pays only eighteen florins a year. With us it is as in England with a certain soap—our families don't feel happy until they get it. It is so cheap that many of the rooms in my hotel are fitted up with it. If the visitor finds it inconvenient to go to the opera, all he has to do is to put this apparatus to his ear, and he can be entertained the whole evening. The general public, too, can have news in advance of the newspapers. Why, a few weeks ago, when the German Kaiser gave that celebrated toast of his to the Hungarian nation, thousands of families were listening to its recital half an hour later. Without this apparatus they would have had to wait until next day."

"Have you a regular daily programme?"

"Yes, it is announced in the morning, and changes every half hour or so. The greater part of the morning is taken up with prices on 'change, a summary of the news in the dailies. At noon we begin to get a report of the doings in Parliament. Telegrams of importance are communicated at once, the Telephonic Messenger being in direct connection with a leading Budapest newspaper. At about 2 o'clock the morning news is in part repeated, then come exchange prices, telegrams, law reports, a short, entertaining story, theatrical items, and sometimes a concert, and for an hour in the evening we get a lesson in English, Italian and French. You have no idea what a benefit this is to the young generation, and how popular these lessons are among them. A complete set of graduated exercises has been published in these languages. Each telephone subscriber who cares to listen holds a copy of the book in question before him, and the teacher speaks into the double microphone transmitter at the central office."—Pall Mall Gazette.

THE UNION TELEPHONE COMPANY has been organized at Portland, Me., for the purpose of acquiring and operating telephone lines and dealing in telephone and electrical supplies. The papers of incorporation call for a $10,000,000 capital stock, of which $300,000 is paid in. The officers are: President, Frederick H. Gorman, of New York City; treasurer, George A. Beaton, of Detroit, Mich.

Fifteenth Annual Report of the Erie Telegraph and Telephone Co.

THE fifteenth annual report of the Erie Telegraph and Telephone Company will show as follows: The principal assets consist of sixty-five per cent. of the $2,000,000 capital stock of the Cleveland Telephone Company, seventy per cent. of the $2,400,000 stock of the Northwestern Telephone Exchange Company, seventy per cent. of the $4,000,000 stock of the Southwestern Telegraph and Telephone Company. These companies operate under American Bell license in Cuyahoga County, O.; in North and South Dakota and Minnesota, except the Black Hills district and the city of Duluth, and in the States of Arkansas and Texas. These three sub-companies show consolidated income and expense accounts as follows for the year ended December 31:

	1897.	1896.	Increase.
Income	$1,412,023	$1,206,147	$205,876
Expenses	871,167	706,135	165,032
Net earnings	$540,856	$500,013	$40,843
Surplus account Dec. 31, previous year	203,806	165,456	38,350
	$744,662	$665,469	$79,193
Dividends	532,000	461,663	70,337
Surplus account Dec. 31	$212,662	$203,806	$8,856

The income and expense account of the Erie Company shows:

	1897.	1896.	Increase.
Income, dividends	$364,550	$314,914	$49,636
Int. and exec. ex.	137,903	106,274	31,629
Net income	$226,647	$208,640	$18,007
Dividends paid, 4 per cent.	192,000	192,000	......
Year's surplus	$34,647	$16,640	$18,007
Surplus from previous year	198,646	182,006	16,640
Total surplus, Dec. 31	$233,293	$198,646	$34,647
Proportion of sub-company's surplus due Erie Co.	146,155	140,164	5,991
Total surplus	$379,448	$338,810	$40,638

Assets and liabilities of the Erie Company, December 31, 1897, were:

Assets—		
Stocks and bonds		$8,507,266.93
Accounts receivable		131,712.29
Cash		119,182.72
		$8,758,161.94
Liabilities—		
Capital stock (issued)	$4,800,000.00	
Bonds and notes	3,630,500.00	
Reserve	94,369.08	
Surplus	233,292.86	
		$8,758.161.94

The report says that the quarterly earnings for the year 1898 may be estimated safely to be at least equal to the last quarter of 1897. Upon this basis the net earnings in 1898 will increase $110,000. Of this amount the Erie Company will receive about $70,000. During 1897 the number of subscribers increased by 3,198 and total number connected December 31 was 24,587, of which 5,421 were at Cleveland, 7,196 in the Northwest and 11,970 in the Southwest; total exchanges in operation, 65; total number of cities and towns connected, 510; expended on plant and equipment during the year, $1,591,305.72, of which $1,171,521.31 was for new construction, $231,284.41 was for maintenance, and $188,500 was for real estate. From 1883 to 1897 inclusive, number of subscribers has increased by 18,596; in that period, a total of $6,436,756.68 has been spent on the plant exclusive of original cost; fifty-seven dividends have been paid by the Erie since organization. The sub-companies own land and buildings valued at $578,500. They have 15,630 miles of wire underground, an increase of 3,822 miles in 1897. Wire mileage has increased 13,819 in the year and the total in operation is 55,851 miles. Estimated construction and real estate expenditures for 1898 are $1,000,000 As funds are needed for growth of the business the capital stock

of the sub-companies is increased from time to time, the Bell and the Erie taking their proportions at par, pro rata. The Erie has a five per cent. bond issue, $4,000,000 authorized, to provide funds for taking its proportion of sub-companies' new stock, all of which bonds have been sold, deliverable as the company needs the funds; $2,000,000 have been delivered, making total outstanding indebtedness of the Erie $3,630,500; the sub-companies have no outstanding debt. Earnings of the long distance service increased thirty-six per cent. for the year.

A Swiss Telephone Joke.

A telephone story from Switzerland: A well-known cattle dealer in Berne telephoned to the slaughter house there that he had sent a goodly number of calves thither. At the central station an error was made in the word, as, instead of "Schlachthaus," the word "Rathhaus" (City Hall) was used, and the telephone was placed in communication with that institution, just previous to an important debate. Herr Weibel Häubi, responding to the telephone signal, had his usual serenity ruffled by the inquiry, "Have all the calves arrived yet?"

Government and Private Telegraphs in Mexico.

Consul General Donnelly, writing from Laredo, Mexico, says: "An interesting phase of government ownership of public utilities is being presented in Mexico, where the Government operates a telegraph line of its own in competition with the lines of the several railroads. Advocates of government ownership would doubtless expect the government service to be the cheapest and best. Such, however, is not the case. The railroads give the promptest service and generally at lower rates. The following table shows the government and railroad telegraph rates on ten words from Nuevo Laredo to the cities named:

Nuevo Laredo to—	Government rate.	Railroad rate.
Monterey	$0.40	$0.26
Saltillo	.60	.51
San Luis Potosi	1.20	1.16
Mexico City	1.60	1.61

"As a natural consequence, the railroads have done the great bulk of telegraph business, both foreign and domestic."

NEWS AND NOTES

The Omaha Exposition.

The illumination of the grounds and buildings of the great exposition, for which Omaha is now preparing, will be made on a scale of magnificence unexcelled even by the wonderful effects obtained at Chicago in 1893. Mr. Luther Stieringer, the lighting expert of the World's Fair, is consulting electrician for the Omaha Exposition Company. Not less than 2,155 kilowatts in dynamos and transformers have already been ordered from the General Electric Company, for purely illuminating purposes. In detail, the contract covers four 125 2,000 candle power Brush arc dynamos, of the multi-circuit type; four 120 kilowatt and two 180 kilowatt alternating current, high periodicity dynamos, operating at 1,040 volts, together with 840 kilowatts in type H transformers of different sizes. Current for various power purposes will be supplied from a generator of 225 kilowatt capacity operating at from 500 to 550 volts.

The arc lamps will number 600, of 2,000 candle power each. These are to be of either the double or single carbon type at the option of the General Electric Company, but, if the latter are used, they are to be arranged for fourteen hour service. The contract also calls for the necessary exciters and all the switchboard appliances for the operation of the above machines.

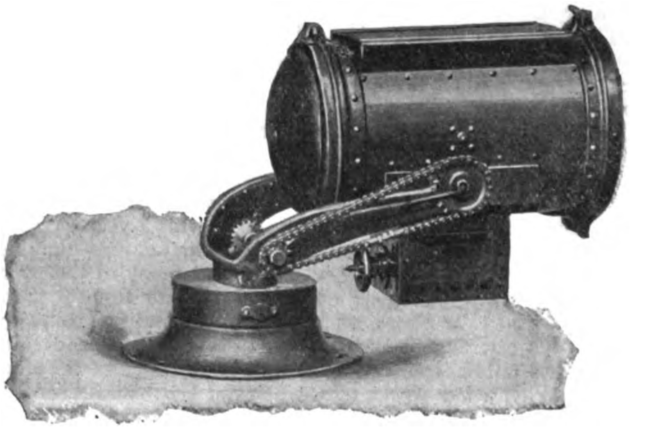
NORRISTOWN, PA.—Falkenau Electric Company, of Philadelphia, have a contract for a city plant to be furnished at a cost of $41,191.

ELECTRIC LIGHTING

New Rushmore Marine Projector.

We illustrate herewith a new type high power lens mirror projector lately brought out by the Rushmore Dynamo Works, of Jersey City, N. J., who, as is well known, make a specialty of marine equipment. This little light is intended for the smaller class of yachts of 100 feet or under, and is not too large for the smallest boat that can float a dynamo to supply the current. The lens is 9 inches in diameter and the total height 15 inches and weight 40 pounds. It throws a clear round solid beam, and with 8 amperes will show up a buoy about one-half mile away on a dark night. The first projector of this type was installed on the racing yacht "Presto," built by Mr. Chas. D. Mosher for Mr. Wm. Mollenhauer. The beam is controlled by two distant controllers, one in the pilot house and the other aft on the bridge.

The Rushmore works are building projectors in all sizes up to 72 inches diameter for all classes of naval and commercial service. They have cut free from the foreign lens makers and now claim to have the finest lens-making plant in the country. They not only grind and polish the lenses, but prepare the special glass required and have lately installed a large sweating furnace heated with crude oil vaporized by heated compressed air. Selected pieces of the prepared glass are placed in fire clay moulds of the shape of the rough lens, and the heat is gradually increased until the glass "sweats" down between the halves



RUSHMORE LOW BASE MARINE PROJECTOR.

of the mould and the surplus oozes out from the sides. As soon as the "sweating" is completed, the mould is placed in an oven and buried in red hot sand and the temperature is gradually reduced over a period of two weeks. The glass when cold has become thoroughly annealed and will stand the severe heating and chilling to which it is exposed in the searchlights without risk of breakage.

The grinding is done in large machines which sweep out the true parabolic curve with an accuracy that has heretofore been considered impossible, and were it not for the fact that the crater of the positive carbon from which all the projected light comes is of considerable size, instead of being an infinitesimal point as is the focal point of the lens, the beam would not spread at all, but would appear to an observer near the light to run to a point and disappear. The inevitable spreading due to the crater is in practice just the amount required to equal the parallax and thus to the operator the beam appears perfectly parallel.

The Rushmore works have during the last week sold over fifty projectors for all classes of service. Seven 14-inch projectors are being shipped to San Francisco, and four of the same size to Portland, Ore., for a steamer fitting out for Alaska. They also sold a complete plant consisting of one 6 kilowatt and one 30 kilowatt direct connected generating sets, switchboard and a 45 ampere projector for the Alaska steamer "Cartina," now fitting out at Elizabethport for the Boston-Seattle Company, and on the same day they closed a contract through their Baltimore agents, D. E. Evans & Co., for a 12 kilowatt

generating set and a 25 ampere projector for the steamer "Susquehanna."

Electric Lighting Consolidation in Philadelphia.

Formal announcement was made on Feb. 15 that a controlling interest in the stock of all independent electric light companies of Philadelphia had been acquired by the Pennsylvania Manufacturing Light and Power Company, incorporated under the laws of New Jersey, with a capital of $15,000,000. The announcement is made by Mr. Martin Maloney, president of the Pennsylvania Heat, Light and Power Company, which absorbed the local Edison Company through the medium of a collateral trust two years ago. The new company will issue $15,000,000 collateral 5 per cent. gold bonds in exchange for the stock of the minor companies.

No organization of the new $15,000,000 enterprise has been effected yet, but Mr. Maloney will be made president.

MARRIED

Hayden—House.

We are glad to record the marriage, at Marion, N. C., on February 22, of Mr. Hobart D. Hayden, superintendent of the Suburban Electric Light Company, Scranton, Pa., to Miss Edith E. House, of that city.

SOCIETY & CLUB NOTES

National Electric Light Association.

The next meeting of this association will be held in Chicago, Ill., June 7, 8 and 9 next. The headquarters will be at the Auditorium Hotel. The rates for accommodation at the hotel will be from $3.50 to $5 per day on the American plan, or $2 to $4 on the European plan. The hotel gives the association the use of the banquet hall for the meetings. Announcements of papers to be read will be made later. All communications should be addressed to Geo. F. Porter, Secretary, 136 Liberty street, New York City.

Electrical Engineers of the Twin Cities at Dinner.

THE electrical engineers of the Twin Cities, to the number of thirty-five, sat down to a banquet at the Windsor Hotel, St. Paul, on Washington's Birthday. It was an annual feast of the fraternity, the second of its kind, the first having taken place in Minneapolis last year.

Morgan Brooks, of Minneapolis, presided and officiated as toastmaster. Others from that city were Prof. George D. Shepardson, Charles W. Gilchrist, Adolf Wagner, H. F. M Dahl, William Robertson, C. F. Wyman, George W. Hayford, A. M. Laird, James T. Boustead, W. F. Clarke, C. H. Edwards, P. A. Clisdell, W. W. Dokin, F. W. McKellip, Frank E. Reidhead, Robert D. Valentine, W. J. Chapman, James Reardon, J. S. Webster and C. H. Chalmers.

The city of St. Paul was represented by A. Wilford Zahm, F. D. Varnum, John Gorman, J. H. Whitaker, Joseph King, C. E. N. Howard, J. G. Robertson, S. A. Jones, E. J. Larkin, Robert W. Clark, J. J. Schoenleber and E. L. Hart, of the Edison Company. B. B. Downs, of the Electrical Appliance Company, of Chicago, was also a guest.

It was a quiet, pleasant, sociable feast intended to emphasize the sentiment of good fellowship between the representatives of the profession in the two cities.

Mr. Brooks, as toastmaster, began the speech-making in a cordial address. He was followed by Prof. Geo. D. Shepardson.

Mr. Whitaker, of St. Paul, spoke of "The Uses and Abuses of the Telephone.". P. A. Clisdell responded to the toast of the General Electric Company, and J. S. Webster to that given to the Walker Company. John Gorman made some remarks on "Electric Wiring Ten Years Ago and To-day." Mr. Zahm read several letters of regret received from those who were unable to be present. The evening was enjoyed by those who attended as an incident affording recreation and instruction, and it was decided to give these dinners quarterly instead of annually as heretofore, the next one to occur in Minneapolis.

American Institute of Electrical Engineers.

The 122d meeting of the institute was held at 12 West Thirty-first street Feb. 23 and was called to order by President Crocker at 8.30 p. m. About seventy-five members and guests were present. A paper on the "Single-Phase Induction Motor" was read by Mr. Steinmetz and was discussed by Prof. W. S. Franklin, Dr. A. E. Kennelly, Messrs. E. E. Ries, Townsend Wolcott and others.

At the meeting of the Executive Committee in the afternoon the following associate members were elected: Frank Broili, electrical engineer, California Elec. Works; residence, 823 Geary street, San Francisco, Cal. Samuel Byington Libby, superintendent N. Y. & S. I. Electric Co., West New Brighton, N. Y. Otto T. Louis, manager of New York Branch, Queen & Co. Inc.; residence, 340 East 119th street, New York City. James A. Mortland, professor of physics, Faculty State Normal School, 2502 Walnut street, Cedar Falls, Iowa. Chas. H. Schum, electrical engineer, Ideal Electric Corp., 216 Third avenue, New York City. C. E. Sedgwick, agent at San Francisco office, General Electric Co., 15 First street; residence, Berkeley, Cal.

Mr. William Goltz, of Milwaukee, was transferred to full membership.

LEGAL NOTES

Decision on Electric Heaters.—The McElroy Patent Sustained.

The U. S. Circuit Court of Appeals for the First Circuit, at Boston on Feb. 18 rendered a decision sustaining in full both claims of the McElroy patent entitled Electrical Heater, No. 500,288, June 27, 1893. The claims of this patent read as follows:

1. In an electrical heater, a wire wound in the form of a spiral spring extending in a spiral path about a cylindrically formed non-conductor, in such a manner that each spiral shall come into contact with the non-conductor at one point only and the layers of spirals shall be separated from each other, substantially as described and for the purpose set forth.

2. In an electrical heater, the combination of an insulating substance, a wire coiled in the form of a spiral spring extending in a spiral path about said insulating substance, a non-conducting material placed between the adjacent layers of the said spring, substantially as described and for the purpose set forth.

This suit was brought originally against the West End Street Railway Company, of Boston, and defended by the American Electric Heating Corporation, the manufacturers of the car heaters used by the West End Company. On Aug. 27, 1897, Judge Putnam, of the U. S. Circuit Court, rendered a decision holding the heaters to be an infringement on the second claim of the McElroy patent, which he sustained, but denying the validity of the first claim on the ground of its identity with the second. Both sides appealed the case, which has now resulted in the U. S. Circuit Court of Appeals fully sustaining both claims.

The American Electric Heating Corporation inform us that this decision applies to car heaters furnished by them to the West End Street Railway Company some years ago, which were a close copy of those made by the Consolidated Car Heating Company, the American Company at that time believing that the patent in question was not valid. They also inform us that this suit has no bearing whatever on any of the present product of the American Electric Heating Corporation and has no reference whatever to the car heaters which they have been selling for the past three years.

INVENTORS RECORD

Classified Digest of U. S. Electrical Patents Issued February 22, 1898.

Alarms and Signals:—

FIRE ALARM BOX. J. H. Hayes, Appleton and C. Fisher, Chicago, Ill., 599,654. Filed January 21, 1897. Comprises an electrical circuit, a switchboard, electrical conductors leading from different contacts of the switchboard, a switch lever pivoted to the board, an arm connected to the switch-lever, and a starting lever for actuating the switch operating arm.

Batteries, Primary:—

ELECTRIC BATTERY. C. P. Shrewsbury, London, and J. L. Dobell, Modbury, Eng., 599,405. Filed December 24, 1895. Consists of a metallic cell containing an electrolyte, a chamber therein, a pipe leading from the chamber into the electrolyte and suitable means for keeping the electrolyte in a fused state.

ELECTRICAL PRIMARY BATTERY. Joseph Bruce Whittemore, London, Eng., 599,411. Filed September 8, 1896. See description on page 240.

Batteries, Secondary:—

SECONDARY BATTERY. W. A. Crowdus, Chicago, Ill., 599,315. Filed January 25, 1897. Process of forming negative elements in secondary batteries, consisting in immersing plates coated with lead oxide in a solution of sulphate of an easily-oxidizable metal and sulphuric acid, and passing a current to the plates immersed therein.

Conductors, Conduits and Insulators:—

ELECTRIC WIRE HOLDING APPLIANCE. H. A. McCoy, Cambridge, Mass., 599,346. Filed September 30, 1897. Consists of a support carrying parallel fingers pivoted to each other, having means for holding a line-wire, the fingers being held parallel by a spring, and adapted to be depressed by the weight of the line wire and to grip the same.

STRAIN INSULATOR. J. Clegg, New York, 599,493. Filed December 30, 1895. Comprises metallic parts having their abutting faces insulated from each other and connected by an interposed layer of silica vitrified by means of a flux.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. O. B. Skinner and G. M. Bacon, Cleveland, Ohio, 599,480. Filed August 27, 1897. Enclosed arc lamp; details of construction.

SUPPORT FOR INCANDESCENT ELECTRIC LIGHTS. J. Whitaker, Schenectady, N. Y., 599,543. Filed June 19, 1897. Comprises a plurality of separate fractional sections enclosing a spring coil whereby they are held in close contact with each other.

ELECTRIC ARC LAMP. H. J. Sage, Rochester, Pa., 599,635. Filed March 10, 1897. An arc lamp provided with a carbon-socket supported by rods from the base of the lamp and a threaded lower extension; an inclosing casing below the base provided with clips embracing the rods, a globe, and a globe-holder screwed upon the threaded extension.

Measurement:—

DRIVING GEAR FOR ELECTRIC METERS. G. A. Le Fevre, New York, 599,508. Filed April 21, 1897. Comprises a registering device, a motor, and an operative driving connection between the register and motor whereby the register is moved constantly forward without reference to the direction of the motor's rotation.

ELECTRIC IGNITER FOR GAS ENGINES. F. E. Culver, Chicago, Ill., 599,316. Filed February 15, 1897. Combines two relatively movable chambered contacting parts adapted to carry the electric current, and means for supplying the chambers of such parts with fluid.

ELECTRIC IGNITER FOR EXPLOSIVE ENGINES. H. F. Probert, Chicago, Ill., 599,354. Filed April 8, 1897. Details of construction.

Miscellaneous:—

ELECTRIC RESISTANCE CONDUCTOR. H. G. O'Neill, Brookline, Mass., 599,351. Filed January 4, 1897. A resistance conductor for electric heaters, consisting of an oxide compound cast in the form of a rod, having metallic terminal connections attached to each end.

ELECTRIC RESISTANCE CONDUCTOR. H. G. O'Neill, Brookline, and H. B. Gale, Boston, Mass., 599,352. Filed January 4, 1897. Comprises a non-conductive support having a layer of conductive oxide applied to it while in a fused state.

APPARATUS FOR PRODUCING OZONE. M. Otto, Paris, France, 599,455. Filed June 15, 1897. Comprises a casing, electrodes therein, one being movable in relation to the other and adapted to produce and extinguish gradually the discharges at short intervals, means for moving the movable electrode, inlet and outlet openings and electrical connections with a high-tension transformer.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. J. McL. Murphy, Torrington, Conn., 599,344. Filed September 24, 1897. Magnetic switch for surface contact systems.

TROLLEY FOR ELECTRIC RAILWAYS. E. K. Landis, Philadelphia, Pa., 599,393. Filed March 5, 1897. A pivotally mounted guard to retain the pole when the trolley wheel leaves the conductor wire.

ELECTRIC RAILWAY SYSTEM. J. D. Gibbs, Chicago, Ill., 599,604. Filed March 14, 1896. Embodies a supply conductor, a series of contact rails arranged in insulated sections and adapted to be enlivened when forced in contact with the line conductor, the rails overlapping at their ends, and a trolley having two contact-wheels, each provided with a double tread.

Telephones:—

INDIVIDUAL TELEPHONE CALL. T. C. Drake, Malta, Ohio, 599,322. Filed July 31, 1894. For party lines; details of construction.

TELEPHONE SWITCHBOARD APPARATUS. C. F. Dunderdale, Chicago, Ill., 599,553. Filed July 31, 1896. Comprises a hinged lever connected with the subscriber's line and constituting a line-terminal, which lever is capable of vertical and lateral movement, terminals for auxiliary circuits adjacent to the lever and means for holding it out of use.

OBITUARY

Dennis Doren.

Dennis Doren, general superintendent of construction and repair of the Western Union Telegraph Company, died suddenly on February 25 at Norwalk, Ohio. Mr. Doren, who celebrated his sixty-eighth birthday on February 13, was visiting his nephew, Mr. Pitt Curtis, in Norwalk, when death overtook him. He and his wife had just breakfasted and he was about to leave the house to take the train for Washington when he was overcome by an attack of apoplexy. Death was almost instantaneous. Mr. Doren was born on a small farm in the vicinity of Worcester, Ohio, and began telegraphy in 1850. When Superintendent now President Thomas T. Eckert of the Western Union was put in charge of the military telegraph in the Department of the Potomac he appointed Doren superintendent of the construction corps of that army.

Since the war Mr. Doren has acted as superintendent of construction and repairs of the American Telegraph Company, the Western Union Telegraph Company and the Atlantic and Pacific Telegraph Company.

GARDANIER.—We regret to record the death of the wife of Mr. George W. Gardanier, of the electrical engineering staff of the Western Union Telegraph Company, this city.

PERSONAL

MR. T. A. EDISON has begun vigorous litigation against the numerous infringers of his kinetoscope patents.

MR. F. W. HAWLEY. Two receivers have been appointed for the estate of this well known promoter, etc., who has been actively engaged in a large number of enterprises, and is vice-president of the Cataract General Electric Company.

THE STOCK MARKET

The Effect of War Scares.

Wall street was a faithful index last week of the uneasy feeling prevalent throughout the country as to the possibilities of war with Spain, as the result of the Maine disaster. On the whole, the market was wonderfully steady. Uncertainty is always a discouraging feature, and it is likely that prices will advance whatever is finally settled. There is a general and wholesome desire to avoid war, but if it comes, there will be but one result, arrived at swiftly; while the large purchases of all kinds of supplies would meantime greatly stimulate industry. The condition of trade at present is excellent and improving in every respect.

During the week, Western Union sold off from 90¾ down to 86¾ on sales of 47,515 shares. General Electric sagged from 34¾ to 32¼ on 19,420 shares. New York Edison dropped from 133 to 131. American Bell Telephone was weak, and fell from 265 to 251 on sales of 852 shares.

Copper, New York, Feb. 22, was 11.50, an advance of .25 over the preceding week. It bids fair to continue strong. Heavy steel rail is steady at $18.

TRADE NOTES & NOVELTIES

A New Queen Portable Testing Set.

THE convenience and accuracy of a well designed portable Wheatstone's bridge recommend it highly for general resistance measurements. Its chief advantages, outside of the accuracy attainable and its portability, are its extremely wide range of measurement, and its freedom from error. But these advantages are lost unless the instrument is correctly designed in every detail and constructed with the greatest care. A portable Wheatstone's bridge should be compact and complete. It should require no adjustment and have practical immunity from accident or derangement. The range of measurement should be wide and the accuracy as high as will be required in commercial work.

Economy demands that it shall be designed and constructed with due regard to each of the constants, such as sensibility and resistance of the galvanometer, e. m. f., and resistance of the battery, accuracy of adjustment and values of the resistance coils, in order that they may bear such a relation that no

QUEEN-ACME PORTABLE TESTING SET.

one of them shall so influence the result as to unduly diminish the effect, toward securing a high degree of accuracy in the values sought.

Queen & Co., of Philadelphia, have had on the market for several years their Queen Acme portable testing set, designed to meet the above requirements. How well this result has been secured may be judged from the fact that they are supplying them to telephone companies and electric light stations in this country, South America, Canada, Russia and Japan. Their set is in use on all of the vessels of the U. S. Navy, being approved by the Government for that purpose. Recent improvements of such value have been made in the Queen-Acme as to warrant the manufacturers in calling the attention of the electrical public to their added advantages. The illustration shows the instrument in its new form. A most important improvement has been made in the galvanometer whereby the sensibility has been increased sixfold, greatly extending its range of measurement and correspondingly adding to its accuracy. Another improvement has been an alteration in the construction of the galvanometer, so as to enable it to withstand transportation without injury. The galvanometer is of the D'Arsonal type, deadbeat, requiring no adjustment previous to using, and unaffected by external magnetic fields or mechanical vibrations.

As to the range of measurement, the theoretical limits are from 1-1000 of an ohm to 11,110,000 ohms. Practically the range is from 1-100 of an ohm to 5,000,000 ohms. In the case of the lower limit it gives a result accurate to one per cent. When measuring five megohms the accuracy is two per cent. For intermediate values the accuracy is much higher, being throughout most of the range nearly one-fifth of one per cent.

Owing to the long galvanometer scale and the flexible arrangements of its connections, the range may be considerably extended beyond that given above. For example, a battery of high e. m. f. and a direct deflection method permits of insulation comparisons as high as 20 megohms. The coils are of special wire, carefully seasoned and adjusted to a considerably higher degree of accuracy than heretofore. By suitable connections, the galvanometer or battery may be used independently of the rest of the set or they may be used jointly in series with the rheostat.

A comprehensive pamphlet descriptive of the Queen-Acme set is about ready for the press and will be mailed to all interested parties on application.

Current Economy Due to Change of Car Controllers.

The high economy obtained with the General Electric K2 type of series parallel controller, while fully appreciated wherever the new type of controller is installed, has not, it is claimed, been shown in such concrete shape as to bring conviction home to managers of railway systems using the older rheostatic controllers. The following data from a road which has changed its controllers without material change in its other apparatus will, therefore, prove interesting. In April, 1897, the San Antonio (Texas) Street Railway Company, which had previously used rheostsatic controllers on its cars exclusively, began to substitute the K2 series parallel controller. The cars are equipped with Thomson-Houston F 30 and Edison No. 6 double reduction motors, and were formerly controlled by rheostatic controllers. To supply current to the twenty-six cars in operation required four 125 h. p. Armington & Sims engines driving two 10 k. w. Edison bipolar, and two T. H. M. P. 80 railway generators. The load varied from 450 to 650 amperes and considerable difficulty was experienced in maintaining the pressure at the station at 500 volts.

When K2 controllers were substituted, the load at the station decreased to an average of about 350 amperes, ranging between 270 amperes and 400 amperes, and with so much less rapid variation that with three engines and three generators only, the load is carried with ease. Were it not for several grades of 5 per cent. and 6 per cent. at the extreme ends of the lines, the twenty-six cars in service could as easily be operated by two engines and two generators, but the propulsion of the cars up those grades causes the load to rise above the capacity of the two units. It is worthy of note, however, that when the three units are in service, the use of the K2 controllers allows an increased load of from eight to ten additional cars.

A further benefit derived from the use of the K2 series parallel controllers is the economy arising from repair expenses on the armatures and fields of motors. Mr. W. R. Weiss, president of the San Antonio road, who has kindly given out these facts, says: "No road can afford to continue the old style of controlling apparatus, and, had we known the saving we should make, we should have adopted the series parallel controllers long ago."

Safety Conduit Co.'s Loricated Conduits.

The Safety Conduit Company, Rankin Station, Pa., are the manufacturers of the "Loricated" electric conduits, unlined, and made from standard gas pipe, to which they exactly correspond in thickness of wall and all other dimensions. They are enameled inside and outside with a tough smooth coating which does not crack when the conduit is bent. The tubes are in 10 feet lengths, with a coupling on one end and a thread on the other. The interior of the tube is highly smooth. If need be, light wall tubing can also be furnished, when specially called for. This Loricated conduit, it is claimed, excels all others, in regard to the ease and economy with which it can be installed, and its quality is attested by the fact that it has been approved for use by the National Board of Fire Underwriters. Mr. Robert Garland, the treasurer, informs us that the material has recently been installed in the following important buildings: Post Office,

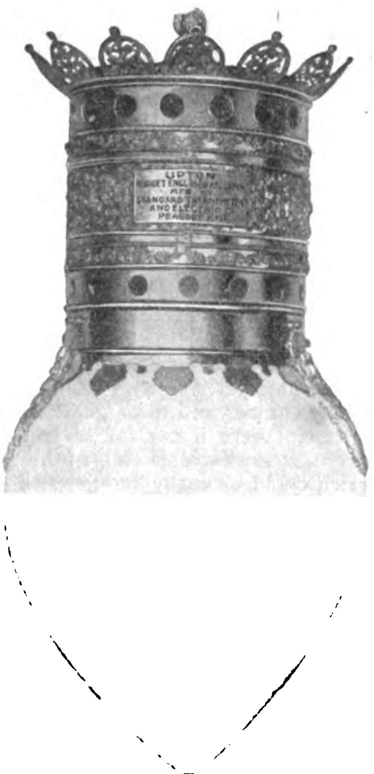
Washington, D. C.; Carnegie Library, Homestead, Pa.; Carnegie Library, Lawrenceville, Pittsburg; Commercial National Bank, Monongahela National Bank, Jos. Homer & Company Building, Pittsburg Leader, all in Pittsburg; and the Eleventh Ward School, Allegheny City. The company is busy on a variety of contracts, and will be glad to receive inquiries and give estimates or other information.

The "Midget" Long Burning Alternating Current Lamp.

THE success which has attended the introduction of enclosed arc lamps for use on low tension direct current circuits, immediately created a demand for an equally good lamp to be used on alternating circuits. In fact a lamp for this purpose, which would meet the requirements in every way, seems to have an unlimited field. In many places where low tension direct current circuits were not feasible, and especially for store lighting, by electric light stations, incandescents have been used, as the old style alternating current open arc lamps were not desirable and made more or less noise. Some manufacturers have recently placed enclosed arc lamps on the market to burn on alternating current, among whom are the Standard Thermometer and Electric Company, of Peabody, Mass., makers of the "Upton" midget lamps.

The accompanying cut represents their lamp designed for indoor service. Elsewhere in The Engineer will be found their outdoor type.

It is claimed that this lamp combines all the elements of simple



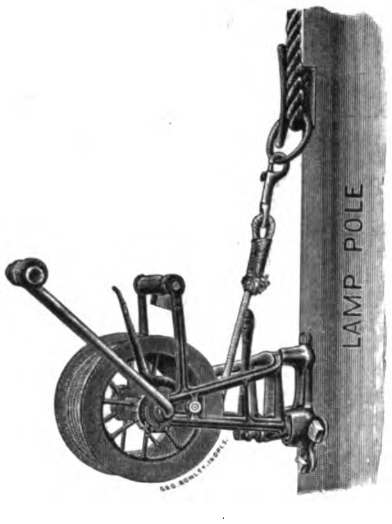
INDOOR TYPE OF "MIDGET" LONG BURNING ALTERNATING ARC LAMP.

mechanism, steady and perfectly noiseless burning with economy of operation.

On circuits of 16,000 alternations the lamp operates direct from a secondary of from 100 to 125 volts without any transformer or resistance at an average consumption of 360 watts per hour. For circuits of 7,200 alternations an induction coil is placed in the cover of the lamp, which otherwise operates like the high frequency type, showing an average consumption of 400 to 425 watts per hour. The makers guarantee for their lamp a life of from 100 to 125 hours at one trimming.

The "Midget" lamp has given the best of satisfaction wherever tried and the "Standard" people claim their lamp has proven successful thus far in all competitive tests. A new catalogue has just been issued which can be obtained by writing either to the main or branch offices of the Standard Thermometer and Electric Company.

Carr's Detachable Windlass.



THE windlass shown in the accompanying illustration is designed to raise and lower electric street lamps for trimming. Only one windlass is required by each trimmer, and it can be attached or detached in a second's time. Each lamp pole is provided with a pole socket or support for the windlass, which is permanently and securely fastened to the pole by three lag screws, and when the windlass is once attached to socket or support it cannot become loosened by accident, making it as safe as if it was bolted directly to the pole. It is very light, strong and neat, being nickel-plated and enameled, and all parts liable to wear are adjustable. The low cost in fitting a street lighting plant with this windlass, makes it within the reach of all, and as the lamp can be raised or lowered without the breakage of globes, suspension wire and the liability of throwing the lamp out of adjustment, this saving alone would soon pay for the windlass. The apparatus is manufactured by E. M. Carr, New Castle, Ind.

Spencer Trask & Co.

This well known New York firm of bankers is one of the largest of its kind and does an extensive investment business. It makes a specialty of dealing in the bonds and stocks of the Edison Illuminating Companies of New York and Brooklyn, the firm having been closely identified with both these properties from their inception. Mr. Trask has been president of the New York Edison Company for fourteen years.

Those desiring information concerning electrical securities, or who wish to invest in them, will be given the closest attention by this representative firm, at 27 Pine street, New York.

When the Wind Blows.

In advertising the Victor split insulator and swinging tree insulator, the Western Electric Company has issued a neat little circular, the cover of which says, "When the wind blows, protect your lines." It is certainly good advice as there is nothing more aggravating to the central station manager than to have the lines break down and cut off the supply of current to the customers.

Red Heat Resistances.

A new type of resistance suitable for sudden overload, and which can be run at almost red heat for an indefinite time, is offered by the Ward Leonard Electric Company, Bronxville, N. Y. This type of resistance is especially suitable for use in connection with motors on cranes, elevators and printing presses, and general motor starting service. It is said to be very compact and of large heat absorptive capacity, while it is well provided with exterior blades for rapid cooling.

C & C Special Motors.

A great deal of work is being done now by the C & C Electric Company, of this city, in the line of special types of machines for special purposes. Among their present orders of this kind is one from the Pope Manufacturing Company, of Hartford, for a big lot of special motors of very light weight and high efficiency to be used in propelling new Columbia motor carriages.

C & C motors have always been well and favorably known for their exceptionally high efficiency, excellence of design and construction and satisfactory operation; and those well known facts have gone a long way in attracting toward the C & C Company many manufacturers of machinery desiring special types of motors for mounting in connection with their own product.

The Wagner Electric Mfg. Co.

A number of changes have recently been made in the management of the Wagner Electric Manufacturing Company, of St. Louis, the general managership of which has been placed in the hands of Mr. S. B. Pike, secretary of the Missouri Edison Electric Company.

Mr. Pike will be seconded by Mr. W. A. Layman, assistant general manager, who will take personal direction of the details of the business in all matters of an executive nature.

Mr. Eugene H. Abadie will devote his entire time and efforts to the sale of the company's products, and Mr. Fred. Schwedtmann, who has so ably conducted the design and manufacture since the company's inception in 1892, will continue as superintendent of the manufacturing department.

Mr. H. A. Wagner, being one of the company's board of directors, will continue his active interests in an advisory capacity.

The Buchil Power and Irrigation Co.

THE Buchil Power and Irrigation Company, of Cuero, Texas, has been incorporated with a capital stock of $50,000. The company has built a power house on the Guadelupe River, whose power can be utilized to the extent of 700 h. p. by the building of a stone and concrete dam giving a 10 foot head. The power house is built of wood on a concrete and brick foundation and has a corrugated galvanized iron roof. At present only one 180 kilowatt generator and apparatus of the Stanley two-phase a. c. type with Stanley transformers have been installed, and the current is to be used for both light and power service.

The power is transmitted over three No. 2 wires from the dam to the city of Cuero, a distance of 3 miles; and there will be 16 miles of circuits for lights. Current will be supplied to a large number of small fan motors, printing presses, etc., and several 50 to 60 h. p. motors to run cotton gins and machine shops will soon be installed. There is no other electricity supply company within a radius of many miles of Cuero and the company is supplying current at a very reasonable rate. The presence of cotton gins as well as cheap power seems to make Cuero a splendid location for the opening of a cotton spinnery. The officers of the company are: Otto Buchil, president, and C. Aug. Buchil, vice-president.

CATALOGUES.

G. E. Decorative and Candelabra Lamps.

ALTHOUGH a very large number of series candelabra lamps are still in use, a growing tendency exists to employ these lamps in multiple on ordinary circuits, with the result that the wiring of fixtures is much simplified, and the renewal of burned out lamps rendered a much easier task. A full line of multiple candelabra lamps, as well as series lamps is now made by the Edison Decorative and Miniature Lamp Department, which has just issued a handsomely illustrated catalogue in which all the styles of series and multiple candelabra lamps, multiple sign lamps, series decorative lamps, and lamps for special uses, such as bicycle, telephone, dental, surgical lamps, and many others, are described. The department has also illustrated in this little work a complete line of receptacles and sockets for candelabra and miniature lamps.

The catalogue is of interest not only to all central station managers and dealers, but also to general customers, whether experimenter, physician or others using or likely to use lamps of this character. The catalogue may be obtained from the Edison Decorative and Miniature Lamp Department, General Electric Co., Harrison, N. J.

ELBERTON, GA.—Pearl's Cotton Mill, Beverly, Ga., is in the market for 10 miles of telephone wire and five instruments complete. Mr. R. A. Field, superintendent of Swift's Cotton Mills, Elberton, Ga., can give details.

Catalogue of the Pawtucket Brass Foundry.

A very handsome and useful catalogue has just been issued by the Vulcan Foundry Company, proprietors of the Pawtucket brass foundry, at Pawtucket, R. I. It contains illustrations and prices of electric railway supplies, line devices, motor bearings and everything in the line of overhead material manufactured by this company. These special and standard productions have been so long and favorably known that they do not require any extended remarks. Mr. D. L. Goff, president, and Mr. Gardiner C. Sims, treasurer, are both well known by the steam and electrical engineering professions.

Montgomery & Co.'s 1898 Tool Catalogue.

One of the most complete and artistically gotten up tool catalogues which has been issued of late is that of Montgomery & Company, 105 Fulton street, New York. It is of a convenient size, contains over 500 pages with thousands of illustrations of all classes of tools and a complete eight page index. Price lists, tables and a discount sheet are included in the catalogue which will be sent to any address for the small sum of 25 cents. In no better manner could the firm give proof of the fact that they are trying to serve the public than by the following statement in the catalogue: "If you are not perfectly satisfied with the way we treat you, write your complaint and 'kick,' and then if we don't straighten the matter out to your satisfaction, get mad; but don't get ugly until 'you know'; 'we know' what is wrong. Sometimes things go wrong and mistakes happen that we never know about until the customer tells us."

The Safety Insulated Wire and Cable Co.

A VERY artistic pamphlet has just been issued by the Safety Insulated Wire and Cable Company, manufacturers of seamless insulated wires and cables. The pamphlet is so folded that the first thing confronting the fortunate receiver is a facsimile of a coil of wire, to which a tag is attached bearing his name and the number of feet and size of the wire. To illustrate the various uses to which their wires and cables are put, the company present half-tone illustrations of a telephone exchange, a telegraph operating room, an electric light station, an electric street railroad, a marine view, the Niagara Falls power station, a police patrol station, buildings at the World's Fair and the following New York buildings: R. G. Dun, Standard Oil, St. Paul, Syndicate, Bowling Green, Postal Telegraph, Mail and Express, Mills Hotel and Singer. Besides these, the pamphlet contains prices and illustrations of wires and cables, wire tables and a large number of testimonials. The typography is excellent, and the pamphlet does credit to the company and its general manager, Mr. L. F. Requa.

Western Electric Arc Bulletin.

A second edition of the Bulletin of Arc Lighting Dynamos has been issued by the Western Electric Company. On the cover is a handsome cut of a dynamo installed in an electric light plant in Detroit, and there are six handsome half-tone engravings which show in detail the various parts of the dynamo. An illustration of an arc light switchboard as built by the Western Electric Company is also given. A complete table is incorporated in this Bulletin giving the number and type of dynamos, the ampere capacity, the size of pulley, the height of the machines, the floor space, and the approximate shipping weight. This Bulletin should be in the hands of everyone interested in arc lighting. It is numbered 1002.

MR. R. LEWIS, of the Telegraph Construction and Maintenance Company, London, arrived here from Bermuda last week on his way home from laying the Jamaica cable. An interesting piece of news about the company to which Mr. Lewis belongs is that they are making preparations for the great Cape and Australian cable; this cable with its various connections will probably be in the neighborhood of 15,000 miles! A new ship is being built for the purpose which is greater than the combined capacity of their two largest boats and will carry 6,000 tons of cable.

MR. GEO. A. McKINLOCK, president of the Central Electric Company, has been in New York recently making business and social calls.

ADVERTISERS' HINTS

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., are doing an excellent business, a proof of which is shown in the list of installations appearing in their "ad."

HENRY W. BUCKLE, St. Paul Building, New York, the sole manufacturer of the Buckley condenser will send a descriptive pamphlet containing useful information to steam users.

A CIRCUIT BREAKER that cannot be closed on a short circuit is quite a novelty. Write to the Ward Leonard Electric Company.

THE NATIONAL CONDUIT AND CABLE COMPANY, New York, present two excellent letters testifying to durability and reliability of their cables.

DESK CLAMPS FOR DESK LAMPS are offered by the Crouse-Hinds Electric Company, Syracuse, N. Y. Switches, switchboards, panel-boards, socket handles and specialties are some of the other goods they call attention to.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, Pa., are of course prepared to supply anything and everything required in power, lighting and railway work.

THE C & C ELECTRIC COMPANY, 143 Liberty street, New York, are in the field with special motors for operating sub-marine boats and torpedoes, blowers and exhausters. Also ammunition hoists and conveyers, ship steering gear and gun carriages.

SOME INDUCEMENTS ARE OFFERED on BB double galvanized iron wire by the Central Electric Company, 173 Adams street, Chicago. It will pay to learn of them.

THE BALL ENGINE COMPANY, Erie, Pa., say, "If you buy the Ball engine you buy the best."

H. B. COHO & COMPANY, St. Paul Building, New York, are always ready to supply complete electric equipments at immediate notice.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, Ill., have just issued a very neat little catalogue of electric shade lamps showing some new and attractive goods in this line. Let them send you a copy.

THE FULLER COMPANY, Russell street and Grand boulevard, Detroit, Mich., manufacture all styles of electrical ventilating apparatus.

THE WALKER COMPANY, Cleveland, Ohio, call attention to the contract they have secured for the electrical equipment of the Brooklyn Elevated R. R. The types of motors and trucks are more fully described on another page of this issue.

THE DEARBORN DRUG AND CHEMICAL WORKS, 29 Rialto, Chicago, manufacture a vegetable compound for boilers which has proven most satisfactory where tried.

G. M. ANGIER & COMPANY, Boston, Mass., say the story of the Paragon arc lamps is one long tale of success.

THE DUNCAN ALTERNATING CURRENT INTEGRATING METER is recommended as the best on the market by the Fort Wayne (Ind.) Electric Corporation.

A HOT TIME is out of the question where the Bates electric fans are installed. So say D. L. Bates & Brother, Dayton, O., who manufacture them for any voltage, direct or alternating current.

THE HART & HEGEMAN MANUFACTURING COMPANY, Hartford, Conn., say the words "Hart Switch" represent a profit to the user.

DE VEAU & COMPANY, 27 Rose street, New York, are better prepared to furnish their telephone apparatus and supplies. An account of their new factory may be found elsewhere in this issue.

THE ROBBINS & MEYERS COMPANY, Springfield, O., are out with their 1898 type of ceiling fans.

WHEELER REFLECTOR COMPANY, Boston, Mass., advertise special shaped reflectors for special purposes.

THE NATIONAL CARBON COMPANY, Cleveland, O., illustrate their No. 2 style of battery and suggest the trial of a few.

"DON'T TRAVEL—TELEPHONE," is the advice of the New York Telephone Company.

DIRECT-CONNECTED POWER GENERATORS of all sizes and voltages are advertised by the Crocker-Wheeler Electric Company, New York. Motors from 1-12 h. p. up.

GENERAL ELECTRIC COMPANY, New York, present a variety of enclosed arc lamps to suit the very requirements of service.

STANDARD THERMOMETER AND ELECTRIC COMPANY, Boston, Mass., show an outdoor type of the "Midget" enclosed arc lamps.

WESTERN NOTES

THE CENTRAL ELECTRIC COMPANY, Chicago, are carrying complete stocks of Insulac and Armalac, for the insulation of generators, motors and all kinds of high potential work. These two compounds are fast establishing a reputation for permanency and absolute reliability.

CENTRAL ELECTRIC COMPANY, of Chicago, is prepared to furnish from stock India or Amber mica, cut or uncut, in rings, washers or any other standard form, a specialty being made of standard shapes for commutators.

WESTERN ELECTRIC COMPANY is at present recommending an electric spud as a serviceable construction tool. This spud is in the nature of a digging bar provided at one end with a braid of open hearth crucible mining steel, and on the upper end an iron tamper, thus combining a digging bar and a tamping bar in one tool. The length of the spud is 9 feet and it digs three times as fast as an ordinary bar and is only half as heavy. The company are carrying in stock a large supply of Simplex friction tape and Simplex splicing compound. They are also pushing the Tuerk alternating current ceiling fan, for which they have recently received orders from Japan and inquiries from Australia.

WESTERN ELECTRIC COMPANY'S desk fan motors of 1897 were received by the trade with such approval that a strong demand already exists for their improved fans of 1898. They manufacture desk and bracket fans for 110, 220 and 550 volts, also ceiling and column fans. The column fan has two speeds, while all the other fans have three speeds. The 12 inch desk fan for 1898 requires less current to operate it than is used by a 16 c. p. incandescent lamp. This economy over fan motors of the past three or four years shows a great improvement in mechanical detail as well as electrical design. The Western Electric Company will soon issue a 32 page fan motor catalogue listing direct and alternating current fan motors, also battery fan motors, and those interested in fan motors will do well to write for a copy of this catalogue.

THE IOWA TELEPHONE COMPANY celebrated on February 11, in connection with the American Telephone and Telegraph Company, the extension of the long distance lines connecting Cedar Rapids with the principal cities East of the Missouri River.

ST. LOUIS, MO.—The Mississippi Valley Elec. and Mfg. Co. has been formed, with a capital stock of $100,000, half paid up, to make the electric railway appliances and inventions of Mr. John R. Farmer, who has a system to dispense with overhead wires.

"SHADE LAMPS" is the title of a very dainty little catalogue just issued by the Electric Appliance Company, covering their special lines of Espersen, Klemm and Dale electric portables and shade lamps. It is a valuable catalogue for any user or dealer in these goods and will be sent on application.

CINCINNATI STREET RAILWAY COMPANY has closed a contract with the General Electric Company amounting, it is said, to over $100,000. It covers the necessary electrical apparatus to enable the Cincinnati company to change over that portion of its system now driven by cable, the Walnut Hills line, to an electric system. The Boston Elevated Railway, has also placed a contract with the same company for electrical apparatus amounting to the same sum.

MR. R. C. FOSTER, of the Cornman Company, of Cleveland, was a visitor at the Chicago office of The Electrical Engineer last week.

MR. W. R. GARTON has located at 414 Ashland Block, Chicago, where he will represent the Garton-Daniels Electric Co., the Pittsburg Steel Hollow Ware Co., the Massachusetts Chemical Co., and other Eastern manufacturers. He will also sell B. & S. drop forged commutator bars and electric railway

supplies in general, but will not give any attention to minor supplies or repair parts. He is interested in the Raster Carbon Rheostat Co., and is also consulting engineer for that concern. At the last meeting of the Garton-Daniels Co. he was elected general manager.

MILWAUKEE, WIS.—The Edward P. Allis Company are building a huge engine to drive the big new General Electric generator of the Louisville, Ky., Railway Company. It is a vertical, round column cross compound machine, with cylinders 40 x 78 x 48, and wheel 25 feet in diameter, weighing 160,000 pounds. The engine shaft is 27 inches in diameter. It is similar to four supplied to the Metropolitan West Side Elevated Road about three years ago.

PORT HURON, MICH.—The St. Clair Tunnel Company is contemplating converting the motive power for the tunnel from steam to electricity. Ever since the awful casualty of Nov. 28 the officers of the tunnel company have given the subject of electrical propulsion considerable attention, and they have now about decided to equip the tunnel with electrical power at as early a date as practicable. Joseph Hobson, of Montreal, chief engineer of the tunnel company, who has charge of the matter, has visited the tunnel with representatives of the General Electric Company, and a thorough survey was made.

CRESTLINE, O.—Mr. R. C. Foster, president of the Cornman Company, of Cleveland, O., has just taken a ten years' contract for an electric lighting plant at Crestline. The Cornman Company have the contract for the electrical apparatus, and station buildings will shortly be erected. The People's Electric Light and Power Company of Crestline is to be the name of the new local corporation.

LOS ANGELES, CAL.—The Edison Electric Illuminating Company has made a contract with the Alcatraz Company for the construction of a complete conduit system. It is said that the cost will reach $150,000.

KANSAS CITY, MO.—C. S. Sweetland, Benjamin Friedberg and R. J. Ingraham have applied to the city council of Kansas City, Mo., for a franchise to operate an electric lighting plant. They would, if successful, probably enlarge the plant in Kansas City, Kan., where Mr. Friedberg is at present operating. They offer 20 per cent. of the gross receipts to the city.

THE NICHOLASVILLE, KY., TELEPHONE COMPANY, Incorp., has recently been started with a capital stock of $10,000. It has equipped a 100 drop exchange, with apparatus of the American Electric Telephone Company, and has started with 35 subscribers. The rates are $1.50 per month for dwellings and $2 for offices, etc. J. A. Kelly is president, of Lebanon, Ky., and R. Y. McElroy, vice-president. The exchange is over the Farmers' Exchange Bank. There is an opening in the town for an electric light plant.

CLEVELAND, O.—The Lorain and Cleveland Road illustrated and described in The Electrical Engineer last October is said to be the fastest electric line in the world. Its cars run on some sections of the road regularly at the rate of 55½ miles an hour.

NEW ENGLAND NOTES

KENT ELECTRICAL MANUFACTURING COMPANY. —We regret to note that a fire at the factory of the Kent Electrical Manufacturing Company, Worcester, Mass., on February 18, practically destroyed the place and with it their stock of motors. Since then, Mr. A. A. Kent, the manager, informs us, the company have been at work in temporary quarters, as they have a large number of orders on hand for prompt delivery. "We have," he says, "been pushing things since the fire in such a manner that we think, from the shipping standpoint, we shall be back where we were in about two weeks."

BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., are building a new boiler house roof for the Coe Brass Manufacturing Company, at Ansonia, Conn.

CENTRAL STATION MANAGERS find that by using an enclosed lamp for their series arc circuits for commercial work, quite a saving is accomplished. The Paragon enclosed arc lamp for series circuits is having a very large sale among the leading electric light stations. Messrs. G. M. Angier & Company, selling agents, Boston, report that every mail brings them inquiries in regard to their new lamp.

NEW YORK NOTES

THE WARREN-MEDBERY COMPANY, of Sandy Hill, N. Y., has been incorporated to make and deal in electrical apparatus and supplies of all kinds. Its capital stock is $25,000, consisting of shares of $100 each, and the directors for the first year are H. J. Medbery and S. C. Medbery, of Ballston Spa; H. B. Warren, of Yonkers, and W. H. Cunningham, H. E. Tidmarsh, Lincoln Paris and George W. Wait, of Sandy Hill.

VALATIE, N. Y.—The Columbia Electric Power Company, of Valatie has filed a certificate with the Secretary, setting forth that its capital stock, amounting to $100,000, has all been paid in. Its directors include Charles Wild, William H. Wild and George M. Pinney.

MR. E. P. THOMPSON, and Mr. A. C. Coursen, will in April take a suit of offices in the Market and Fulton Bank Building, at 81—83 Fulton street, to secure more room for their growing business in patent law, general law, and mechanical and electrical experting. They have of late been very busy in patent suits.

THE WARD LEONARD ELECTRIC COMPANY thought they had lots of room when they bought the large buildings in Bronxville, but their circuit breaker business has grown so rapidly, the need of more buildings is already felt.

OTIS ELEVATOR COMPANY have been awarded a contract for the electric elevators in the extension to the Bamberger Building, Newark, N. J. There will be five, and the price is said to be $13,000.

MR. F. M. HAWKINS, sales agent for Pass & Seymour and The Crouse-Hinds Electric Company, having found his quarters at 41 Cortlandt street too small for his constantly increasing business, has moved his stock and office to the ground floor store, 23 Dey street, where he has ample room to carry and keep in stock a full line of the above firms' specialties. Mr. Hawkins reports business as good and improving.

THE MICA INSULATOR CO., of 218 Water street, New York; 117-119 Lake street, Chicago, and 12 Camomile street, London, report a heavy increase in the volume of business. Many of the large manufacturers are using their "Micanite" segments in the construction of generators and motors exclusively. The company have made many valuable improvements in their well-known insulation, "Micanite," and are turning out a very fine commutator segment. They would be pleased to send a set of segments for any of the smaller machines, as sample, to electrical manufacturers or repair concerns who may make application. Their M-I-C friction tape and "Empire" cloth are meeting with a large sale. They are used for the winding of fields and armature coils, and ensure the highest possible grade of insulation.

STATEN ISLAND.—The New York and Staten Island Electric Company, in February, 1897, contracted for the installation of about 1,200 h. p. Cahall-Babcock & Wilcox type of boilers in their power station, additional. The company shortly after doubled their order, and now, just about a year later, have given the Cahall people a third order and also a contract to dismantle some other old boilers and rebuild them into Cahall-Babcock & Wilcox type.

MR. W. A. GILES, well known as an electrical and mechanical engineer, has joined the staff of the American Stoker Company, of Brooklyn, whose apparatus is now attracting wide attention and is in great demand.

WARD LEONARD ELECTRIC COMPANY, of Bronxville, Westchester county, has been incorporated; capital, $100,000; directors, H. Ward Leonard, Charles E. Carpenter, Richard H. Mansfield, Jr., and Henry Price Ball, of Bronxville, and H. A. Wise, of New York.

THE COMPLETE WIRING SYSTEM, as established and standardized by the Interior Conduit and Insulation Company, will be installed exclusively in the new Park Row Building, the largest office building in the world. Some 250,000 feet of interior conduit will be used in the installation, which will be made by the New York Electric Equipment Company. The Sprague high speed, vertical, electric elevators will also be used in this building.

THE MACKAY TOMB.—A permit has been granted to the Edison Company, of Brooklyn, to lay wires to the famous Mackay mausoleum in Greenwood Cemetery for the lighting

and heating of the tomb, which is now nearing completion. The wires will be laid in a trench 800 feet long. An altar is to be erected in the mausoleum, and a priest will be assigned to say a requiem mass daily.

ERIE CANAL TRACTION COMPANY held its annual meeting last week and elected, president, Louis A. Von Hoffman; vice-president, Frank W. Hawley; secretary and treasurer, C. T. Lewis, and general manager, Com. P. Vedder. Plans are under consideration from the Walker Company to operate the Short system of electric traction on the Champlain Canal. The Trenton Iron Works have submitted also the Lamb system.

BATAVIA, N. Y.—The Bell Telephone Co., of Buffalo, N. Y., have extended a toll line, connecting Bergen and Churchville, which was opened for service February 5. Batavia has a population of 8,250 by recent enumeration; the Bell Telephone Co. has 225 subscribers, which makes a ratio of one telephone to every 37 inhabitants, a very high percentage.

PHILADELPHIA NOTES

WILMINGTON, DEL.—The Jackson and Sharp Company have shipped eight electric cars to the Pensacola Electric and Terminal Railway Company, of Pensacola, Florida. They are handsome in finish and elegantly equipped. Four of the cars are of the open style, 30 feet long and contain ten benches. The remainder are closed cars, and are 18 feet 6 inches long. All are mounted on Peckham trucks, and are finished in orange on the outside.

THE UNITED ELECTRIC IMPROVEMENT COMPANY have built up a business with their series and multiple lighting incandescent lamps, which has outgrown their present facilities. They are contemplating extensive additions to their works.

PITTSBURG, PA.—The Westinghouse Electric and Manufacturing Company has a contract for three dynamos, with a total capacity of 3,000 lights, for the Bellefield Hotel Company, and the order for engines has been placed with the Ball Company of Erie.

SAFETY CONDUIT COMPANY, Rankin Station, Pa., have installed their "Loricated" conduit recently in the Post Office building at Washington and the Carnegie Library at Homestead. They are busy on a large number of orders.

FOREIGN NOTES

PACKARD ELECTRIC COMPANY, St. Catharines, Ont., E. E. Cary, manager, has started and fitted up an electric club for its members. It is fitted up with books, papers, etc., and there are recreation grounds attached. Mr. Cary is honorary president, Mr. Bingay, president, and Mr. Frank Adams, vice-president.

AHEARN & SOPER.—The contract for all the work in connection with the lighting of the Parliament and Department Buildings, at Ottawa, Canada, has been placed with Ahearn & Soper.

SOUTHERN NOTES

KINGSBURY, SAMUEL & COMPANY.—Messrs. L. L. Kingsbury, S. Herman Samuel and George Reese, who for a long time had charge of the electrical construction department for the Southern Electric Company, have severed their connection with that concern and opened an office at 204 East Lexington street. They will confine their business to electrical engineering and contracting. The Southern Electric Company have abandoned that branch of their business. The new firm have the contract for wiring the new government post office at Washington.

NATIONAL AUTOMATIC FIRE ALARM COMPANY, of Louisiana, 618 Gravier street, New Orleans, has been good enough to favor its friends with a neat box of pencils.

THE CITY OF HARRIMAN, TENN., has sold bonds to install an incandescent light plant of 1,500 lamp capacity. Manufacturers and contractors can obtain information of City Clerk D. W. Thomas.

Vol. XXV. MARCH 10, 1898. No. 514.

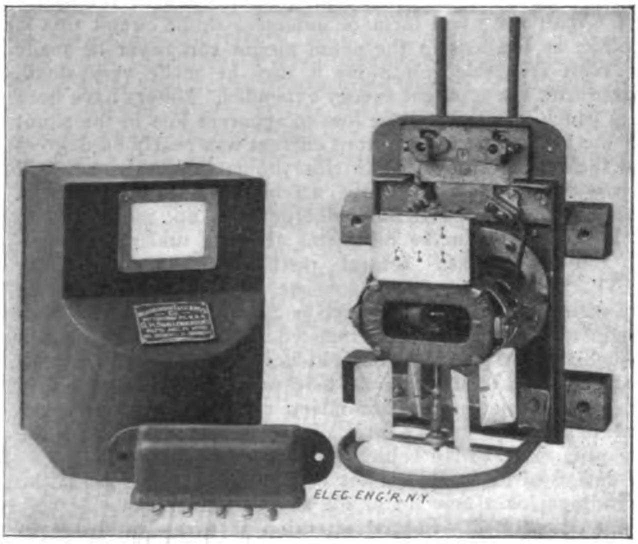
MISCELLANEOUS

The Late O. B. Shallenberger and His Work.

THE recent death of Mr. O. B. Shallenberger removes an inventor who is most widely known through his inventions in electric meters for alternating currents. His current meter, which was developed in the earliest days of the new alternating current system, has never been excelled in simplicity. Over 130,000 have been put into commercial service, and the annual charges for current based on their registration probably exceeds $10,000,000.

This meter was invented in the spring of 1888. It is difficult to appreciate now how little was then known of alternating current phenomena, and how truly those who were producing alternating current apparatus at that time were pioneers. There was practically no literature on the subject, established theories and principles were few, experience was very limited. The only measuring instruments were the Cardew voltmeter and the Siemens dynamometer. To perceive and grasp the underlying facts and fundamental principles in curious and perplexing phenomena, and to apply them to a definite purpose, and construct from them new and useful forms, requires peculiar insight and genius.

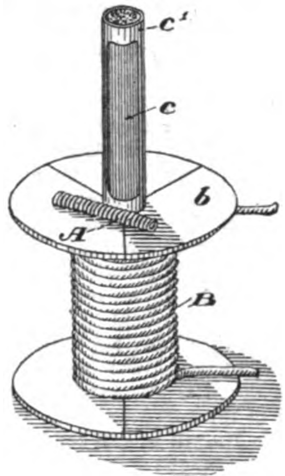
The rotation of a spiral spring which accidentally fell on the top of an experimental arc lamp would have escaped the attention of most people, or would have simply received passing notice as something strange and peculiar. Mr. Shallenberger noticed the action, he investigated the conditions, he foresaw possibilities, he determined the principle, he devised new forms. He possessed to a rare degree the ability to translate ideas into simple mechanical forms. The simplicity and the integrity in the apparatus which he constructed were the legitimate product of his keen and clear-sighted method of thinking.



SHALLENBERGER CURRENT METER.

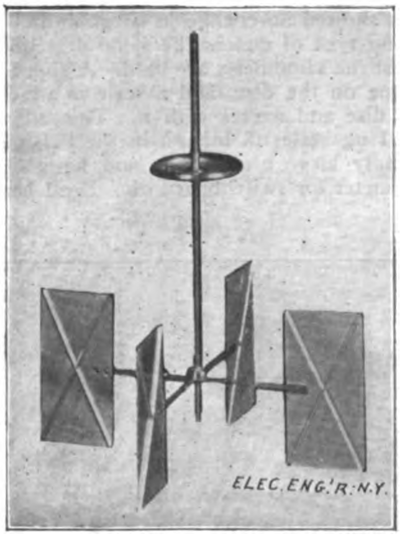
It is seldom that any device stands without change for ten years and without a serious rival. This is particularly true in electrical apparatus during a decade which has seen evolution and revolution everywhere. And yet the Shallenberger current meter, which was invented, experimentally developed and mechanically designed in the short interval of two or three months, had such intrinsic excellence that it has remained unchanged in form or size or other particular, except a few mechanical details. Other successful meters embody elements of design first used in this meter.

Considered simply as a mechanical device the Shallenberger meter is exceedingly interesting. It is a miniature induction or rotary field motor, in which the moving parts, while having no contact with the actuating circuit, are carried around by the rotating magnetic field which surrounds the iron ring armature



COIL, CORE AND ROTATING SPIRAL SPRING WHICH SUGGESTED THE PRINCIPLE OF THE SHALLENBERGER CURRENT METER.

on the meter shaft. This driving force varies as the square of the current, and to make the speed of the meter proportional to the current, retarding air fans are employed, which have a retarding force proportional to the square of the speed. Omitting bearing friction, the driving and retarding forces balance each other at all speeds, and by a simple comparison it is found that the square of the speed varies as the square of the current or the speed of the meter varies as the current. In designing this meter other damping devices were considered and experimented upon, but the simple air fans were found the best. The delicacy



MOVING PART OF SHALLENBERGER INTEGRATING WATT-METER.

of the meter is best illustrated by the amount of power required for the moving parts at full speed. It is only 1-200,000 of a horse power.

In a current meter it must be remembered that the torque or turning force varies as the square of the current, and at starting this is extremely small. As an example: at 1-25th of full load current the torque is 1-625th of that at full load. It is only by very light moving parts and perfect jewel bearings that a meter will start with this current. The form of the lower bearing

enables this delicacy to be secured, and with any other known form the meter would be a failure. The end of the shaft is approximately a hemisphere and rests in an agate or sapphire cup of slightly greater curvature. The weight of the meter shaft, armature and fans is but a little more than one ounce.

Special care is also given in selecting the quality of iron used in the meter discs, as upon this depends the uniform registration with different loads. Hundreds of discs have been measured. Each grade of iron requires a different thickness of disc for the best effect.

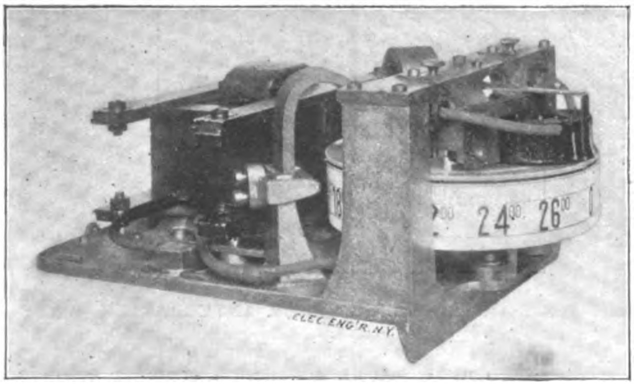
On account of the general introduction of alternating current motors taking currents which may not be proportional to the power delivered, the Shallenberger integrating wattmeter was designed. In this meter lightness of moving parts and the form of jewel bearing which was so successful in the current meter, are retained. It is a peculiar form of two-phase induction motor, in which the rotating part is a plain disc of sheet aluminum. This disc is placed within the shifting field developed by the shunt and series currents, and is carried along by the eddy currents developed within it. There is no connection between the moving parts and the actuating circuits.

The magnetic field derived from the shunt current has such a phase relation to the field of the series current, that the torque on the meter disc is always proportional to the power which this current conveys, independently of any lag which may occur. As the torque is proportional to the power passing the meter (and not to the square of the current) the wattmeter starts with less current than is required in the current meter. With 1-625th full load current the torque is 1-625th of full load torque, and with equal weights of moving parts, the wattmeter has great superiority in starting, over the current meter, which is not due to difference in construction, but in its law of operation.

Retarding force is applied to the disc by two permanent magnets which embrace the disc between the poles. In this way effects of temperature tending to change the speed of the meter are neutralized, since the driving and retarding forces are affected equally. These magnets are of special steel and are artificially aged, by which permanency in strength is secured, which is very important since any change in strength immediately changes the meter speed.

In developing the methods for making these magnets, which occupied several months, Mr. Shallenberger devised a weighing instrument, depending on the force on a conductor carrying a current in a magnetic field, by which the strength of magnets could be measured accurately within 1-10 per cent. In this way any changes in strength could be detected, but magnets were soon made which showed no change in six months.

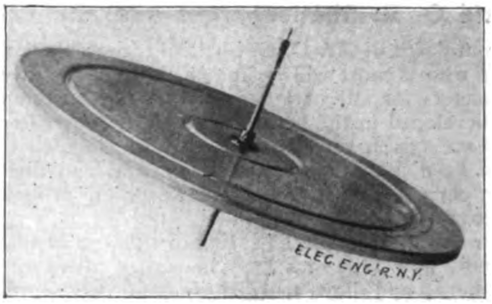
In the indicating type of meters the same principles are employed, and almost the same parts are used. A spiral hairspring opposes the torque on the disc, and a scale is attached to the periphery of the disc and moves with it. This allows the use of an extremely long scale, 18 inches, in the "Niagara Type," and correspondingly large graduations and figures, making a very satisfactory meter for switchboard use. Dead beat qualities



SHALLENBERGER INTEGRATING WATTMETER.

are secured by retaining the magnet used in the integrating meters.

A temperature compensation is required in the indicating meters for variation of resistance in the disc, and Mr. Shallenberger accomplished this in a very beautiful manner by compensating the inductive coil in the shunt circuit, so that more current is allowed to flow as the temperature increases. Other factors remaining the same, the current in the inductive circuit varies as the air gap in the magnetic circuit of the inductive coil, and this change is secured by the difference in the expansion of zinc and iron rods. A variation of only 4-1,000ths of an inch in the air gap of the inductive coil compensates for a variation of 50 degrees Fahr. When this compensating device was



MOVING PARTS OF SHALLENBERGER CURRENT METER.

first made it was found that different instruments were not equally compensated, and the cause was a mystery until it was discovered that in some instruments the zinc strips had been cut with the grain of the metal and in others across the grain.

In order that an induction wattmeter may operate accurately on loads having different power factors, it is well known that the shunt field must be exactly in quadrature with the shunt e. m. f. With the usual form of inductive shunt circuit this is impossible, as the loss in the shunt circuit can never be made zero. With favorable conditions it may be made very small, compared with the apparent energy expended. Meters have been made in which the ratio of true loss to apparent loss in the shunt circuit was .09, or the lag of shunt current was nearly 85 degrees behind the shunt e. m. f. With this shunt circuit a meter will register with fair accuracy on any current commonly met with in commercial practice. Mr. Shallenberger was not satisfied with this. He wished to make his meter accurate under all conditions, and he devised several methods of accomplishing this. That usually employed consists of a small closed secondary within the shunt coil, which is adjustable, either in position or in resistance. Currents induced in this secondary lag in phase behind the magnetic field inducing them, and the new component added to the original field produces a resultant field which, by adjustment of the secondary, may be brought in exact quadrature with the shunt e. m. f. Thus the effective field of the shunt coil is made to lag behind the current in that coil.

The design of these meters has been so systematized that the best windings for a new meter for any particular capacity may be easily determined. Special attention is given to losses in the shunt circuit. While this is small, it goes on constantly when the meter is in service. A smaller loss also implies less compensation to obtain a lag of 90 degrees in the shunt field, and hence less variation due to changes in frequency. Only about three true watts is required in the shunt circuit of any meter, and this decreases as the frequency on which the meter operates is increased. This loss is usually equally divided between C^2R loss in the winding and iron loss in the core of the inductive coil.

In all apparatus made by Mr. Shallenberger there is an admirable completeness in execution. There was usually but a single step from the first model, in which approximate dimensions and laws were determined, to the final working apparatus. There was an absence of successive experimental steps in the development of an instrument, which denotes rare insight into details and foresight in design.

The work of Mr. Shallenberger in connection with meters and electric measuring instruments is that by which he is best known. This was, however, but a small portion of his contributions to applied electricity. In the early days, when there was little theory and less experience on which to base opinions, Mr. Shallenberger, exercising his keen insight and excellent judg-

ment, attained results which have stood the test of time. The design of the early generators and transformers and auxiliary apparatus in the alternating current system, is largely the product of his work. At that time the alternating current system was little known and was the object of intense commercial opposition and the ridicule of many experts. It was in a large measure Mr. Shallenberger's work which gave the alternating current system the initial success which paved the way for its present wide use in this country.

We are indebted to the Westinghouse Electric & Manufacturing Company for thhe above interesting details regarding the late Mr. Shallenberger's pioneer work. We believe with that company that no greater tribute can be paid to the memory of the deceased than to record his work which has accrued to the benefit of the whole world.

An Early Rising Persuader.

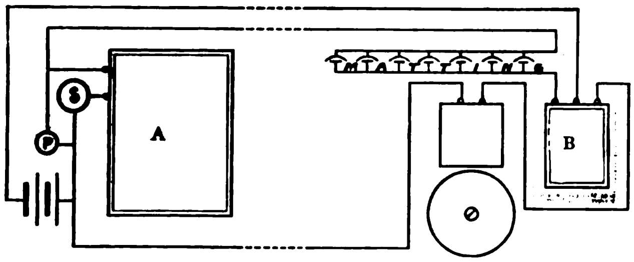
BY RAY D. LILLIBRIDGE.

IN devising an apparatus that will absolutely compel my arising mornings at a regular set time, I believe that I have overcome a difficulty which has never been successfully surmounted before. To be sure we have heard stories and verses of automatic folding beds which, after forcibly ejecting their occupants, snap shut and are only released after the time lock has run down; but it is more often we hear of actual cases where such affairs snap shut without any pretense at delivering their occupants in one piece out into the ambient atmosphere.

Some time ago, after considerable complaint about my failing to respond to gentle entreaties to "get up" mornings, I purchased one of the ordinary electric alarm clocks, which close a bell circuit at any time set and which, with battery and bell, make it necessary for one to arouse sufficiently to throw off the switch.

For a time—till the novelty wore off—this worked very well, and I was declared a "model man," so far as getting up mornings was concerned. But then, notwithstanding that the clock was advertised "a good time keeper," it was very severely affected by changes in temperature, losing or gaining from 20 to 30 minutes as the weather ordained. Besides it had to be wound every day, and when one comes home in the wee hours he hardly feels like giving fourteen screws to an arrangement which is to awaken him in a few hours.

With cold weather came the temptation to crawl back to bed again and have another nap. There is some non-explainable delight, a grim satisfaction, in a few minutes' sleep when you know you are sleeping. Just the dim consciousness that you should be up and around, mingled with the comfort of your situation, that makes you enjoy your stolen nap far more than



(A) CABINET CLOCK. (B) AUTOMATIC DROP.

any other portion of your night's sleep. After once indulging, it is really a task to break off from the habit. It didn't take long to make the "electric alarm clock" obsolete.

My next move was to place an automatic drop away over in the corner of my room furthest away from the bed, and provide the kitchen with a push button. Touching the latter dropped the drop, which in turn threw into circuit a four-inch bell over the headboard of the bedstead. To stop the bell ringing I must lift the drop, and if I chose to go back to bed another push would compel my arising again.

For a long while this arrangement worked admirably. Then we got a girl who couldn't understand why she should push that button more than once (if she thought to do it at all). All the orders, threats or entreaties couldn't make her see that she was hindering the progress of the household by her forgetfulness or maliciousness.

After inconvenience and loss from not being on time in town when I was needed, I conceived the idea herewith illustrated and described. It has been working both summer and winter, and has yet to fail me, notwithstanding that on several mornings I have actually tried my best to "get around" it.

First I took a good cabinet clock that had a mechanical alarm, and connected thereto an electrical attachment, so arranging it that they might work either independently or together. I finished the job up nicely, placing binding posts on the side of the frame and concealing all wires, etc. The clock is an excellent timepiece and has been in actual service some years. For two reasons I left it in its old place on the kitchen clockshelf. One reason was that it might still set the household time; the other that I might not open the circuit at the binding posts in case of a particular lazy spell.

It may be noted in the diagram that all connections, such as battery, switch, etc., are with the clock, two flights downstairs, excepting those on the bell and the automatic drop. These I tightened with a pair of pliers so as to make unscrewing with the fingers absolutely impossible. I then purchased 2½ feet of 36-inch burglar alarm matting, and placed this between the mattress and spring of my bed, putting it in circuit with the automatic drop by means of flexible cord. The pressure of bedclothes, mattress, etc., is not enough to make a contact, but to put one's weight on the bed is sufficient.

The clock may be set to close the circuit at any hour and it keeps it closed for about one hour. At present I wish to arise at seven o'clock, the circuit is therefore closed from seven to eight and open between the hours of eight and seven. Sunday mornings I sometimes like to sleep later than on other days, and by throwing off switch S the night before, I am not disturbed. The button P is, however, easily pushed, but will only work when some one is in the bed. This by itself is a great item. Many times, prior to the installation of the matting, meddlesome fingers had pushed that button, necessitating a trip upstairs when no one was there to stop the bell ringing. Or worse yet; causing the bell to ring till the battery run down. The clock naturally closes the circuit at seven in the evening, but as it is open at the matting the drop does not fall.

I may be retire as early as eight o'clock and will be awakened at precisely seven the next morning by the four-inch gong, to stop whose ringing I must cross the room and lift the drop. Now, should I go back into bed, the contacts in the matting will immediately close the circuit, dropping the drop, starting the bell which will continue its ringing till the drop is again raised.

In practice I find that once knowing that it's "all up" and there is no use trying to get back to bed, I don't make the effort, but at once begin preparations for "business" and soon forget all about sleep. Should anyone install a similar arrangement I will be glad to hear their experience.

The Hargreaves-Bird Electrolytic Alkali Process.

THE experimental plant at Farnworth, near Widnes, England, for the production of alkali and chlorine in the Hargreaves-Bird form of cell by the electrolysis of common salt, was recently inspected by John B. C. Kershaw, F. I. C., who gives the following interesting account in "The Electrician" of the details of the plant and its working results:

The plant has now been running at Farnworth almost continuously for over two years, and many improvements in details of form and working have resulted from the experience gained during this long period of trial. The power at Farnworth is supplied by a gas engine of the well known Otto type, running at 175 revolutions per minute and generating 20 h. p. This engine drives a dynamo made by Holmes, of Newcastle, by belting, the mean speed of the dynamo being 350 revolutions per minute, and the output 2,200 amperes at 5 volts pressure. There is considerable loss of energy occurring in the dynamo at Farnworth on account of the low voltage required. When a large number of decomposing cells are coupled in series it will be possible to utilize currents generated at from 50 to 100 volts pressure, and an efficiency of 94 per cent. will no doubt be attainable. There is also some unnecessary loss of energy in the conductors, a drop of 0.35 volt being observed in the comparatively short lead between the dynamo and the electrolytic cell. Copper conductors of 2¼ square inches sectional area are used. The electrolytic cell in which the whole of the electrical energy delivered by this conductor is being utilized is raised by a brickwork foundation about 2 feet from the ground, and is internally 5 feet deep, 10 feet in length and 14 inches in breadth.

It is divided into one inner anode chamber and two outer cathode chambers, in the manner described in the previous article on this process. The figure represents diagrammatically a vertical end section of the cell with one of the anodes in position in the anode chamber. This inner chamber of the cell is almost filled with the brine, which is maintained in continual circulation through it, and at a constant level. The outer cathode chambers are kept constantly supplied with steam and carbonic acid gas (the exhaust from the gas engine supplies the latter at Farnworth); the solution of sodium carbonate formed on the wire gauze cathodes collects at the bottom of the chambers, and is continually running off by the pipes shown in the diagram. The diaphragms are 5 feet 4 inches by 10 feet 4 inches, including overlap at the edges, leaving 5 feet by 10 feet of active surface inside the margin. Mr. Hargreaves considers these dimensions as large as are practicable at present, but they may, no doubt, be increased when more experience in handling them has been acquired. The cathode area in the cell at Farnworth with two of these large diaphragm-cathodes is, therefore, 100 square feet. The anodes at present in use are compound ones, formed by boring perfectly round 3-inch holes in a number of roughly-shaped blocks of gas carbon, and by fitting these upon a round shaft of lead-copper alloy. A special cement is used to protect this shaft from the action of the brine and chlorine, in parts that would otherwise be exposed. This novel form of anode, the general appearance of which is shown in the figure, is the invention of Mr. Connor, of Belfast, and the patent is now owned by the General Electrolytic Parent Company, who likewise control the Hargreaves-Bird patents. A row of six of these compound anodes connected in parallel extends from side to side of the anode chamber, and they are said to be much superior in every respect to the flat plates of carbon which were formerly used. The chlorine gas produced at the anodes rises to the surface of the liquid, and is led away by the pipe which carries off the overflow of the brine. The brine and chlorine are conducted to a separating well, where the brine is re-saturated with salt, and is returned by a pump to the cell, while the chlorine gas is led to an absorbing chamber or tower, for the production of bleaching powder or chlorate of soda. At Farnworth it is possible to use the chlorine produced in the cell for either purpose, and on the occasion of the writer's visit bleaching powder was being produced. Both the bleaching powder and chlorate manufactured by the plant in operation at this place are stated to have been of excellent quality. The alkaline liquor flowing from each cathode compartment of the cell was sampled in the presence of the writer for the London "Electrician," and found

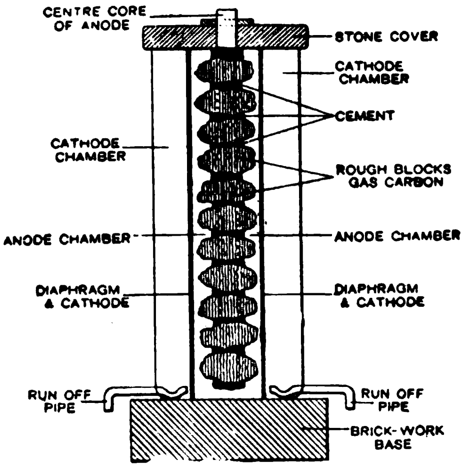


FIG. 1.—DIAGRAMMATIC VERTICAL SECTION OF THE HARGREAVES-BIRD ELECTROLYTIC CELL.

to possess a specific gravity, in one case of 1.125° and in the other of 1.112°, measured hot.

These samples were bottled and sealed, and have since been tested with the following results:

Mean Sp. Gr.	Mean Percentage Na_2CO_3.	Mean Percentage Na Cl..	Molecules Na Cl per 100 Mol. Na_2CO_3.
1.125	10.90	0.94	15.6

The amount of undecomposed salt in these samples was very much higher than that found under normal working conditions. The increase was attributed by Mr. Hargreaves to the use of the diaphragms ten days longer than was customary. Those in use on the occasion of this visit had been in the cell from October 12—that is, for a period of forty days; whereas the diaphragms were not usually worked beyond thirty days, and this was regarded as the limit under normal conditions of work.

In order to obtain further information upon this point, the writer paid a second visit to the works on January 7, and obtained samples of the liquor flowing from the cell as before. The diaphragms on this occasion had only been in use thirty-six hours, and were practically quite new. The samples were bottled and sealed; the tests have yielded the following results:

Mean Sp. Gr.	Mean Percentage Na_2CO_3.	Mean Percentage Na Cl.	Molecules Na Cl per 100 Mol. Na_2CO_3.
1.094	10.44	0.10	1.73

The molecules of undecomposed salt per 100 molecules of sodium carbonate are in this case very low, and the figures therefore support Mr. Hargreaves' statement, that under normal working conditions as regards the age of the diaphragms, the proportion of undecomposed salt in the solution of alkali flowing from the cell can be kept within satisfactory limits.

The current passing through the cell on the occasion of the second visit was 1,800 amperes, and the e. m. f. at the cell terminals was 5.40 volts. It was stated that the e. m. f. necessary to overcome the resistance of the diaphragms would diminish as they became older, and that consequently the amperes of current passing through the cell would increase. Neither free chlorine nor hypochlorite were present in any of the samples of liquor taken from the cathode compartments of the cell.

At Farnworth this alkaline liquor is boiled down and is then allowed to crystallize. Sodium carbonate with 10 molecules of water (the deca-hydrate) is obtained. It is optional whether this form of alkali, soda ash, or caustic alkali shall be produced by the process, and the decision in the case of the larger plants which are about to be built will depend upon the relative market-sale prices of these products.

The quantity of salt decomposed in the cell now working at Farnworth was stated to be about 220 pounds (dry) per twenty-four hours.

The following figures represent the details of the previous run and of the one in progress at the date of the writer's first visit. The cell is run continuously, seven days per week, until the diaphragms require renewal.

Period of Run.	Mean Current Amperes.	Mean E.M.F. Volts.	Salt, Lbs per 24 Hours.	Efficiencies Per Cent.	
				Current.	Energy.
Sept. 15–Oct. 11..	2031.5	4.2	217.3	92.7	50.05
Oct. 12–Nov. 22..	2089.3	4.24	218.06	90.4	48.99

The brine in the inner compartment of the cell is maintained at a temperature of 70° C., partly by the current and partly by the transmission of heat from the steam through the diaphragms. The higher current-density now being employed (from 20 to 22 amperes per square foot) is purposely used in order to obtain a greater output of alkali and chlorine from one cell, and this is held to compensate for the slight increase of voltage that may be traced to this cause.

New Lightship For the Delaware Coast.

Light Vessel No. 71, doubtless the best craft of her kind in the world, has left Bath, Me., for the Edgemoor Buoy Depot, situated four miles above Wilmington, where she will be turned over to the Government. Each mast supports three lanterns, and in each lantern is a light hung with ball and socket joints. There is a flashing device on the dynamo bed-plate which causes the lights to burn twelve seconds between intervals of four seconds, thus showing four times per minute. The electric lights can be seen eleven miles away.

CITY OF MEXICO.—A company has just been organized in London, England, under the name of City of Mexico Electric Power Syndicate, Limited, with a capital stock of $25,000 (gold). The object of the new company is to acquire any rights and grants for producing electricity for lighting, motive and other purposes in Mexico, and to carry on the business of electrical engineers and contractors. The directors of the company are R. J. Price, H. K. Baynes and J. F. Toomer. The company will open an office in the city of Mexico in a short time.

ELECTRIC LIGHTING

The Electric Power Plants in Reading, Pa.

BY N. MONROE HOPKINS.

PROMINENT among the many successful enterprises in Reading, a city destined to become one of the great manufacturing and industrial centres of the country, is the combined power plant of the Metropolitan Electric Company, and the United Traction Company, upon which talent and capital have been assiduously and unsparingly applied. From the inception of the company in March, 1883, incorporated as the

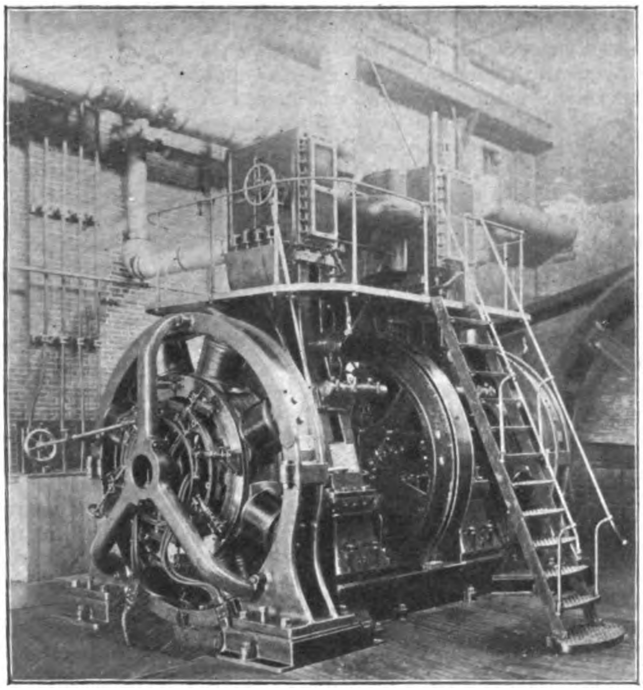

FIG. 1.—INCANDESCENT LIGHTING UNIT.

Reading Electric Light & Power Company, to the present time, the demand for light and power has exceeded the supply, and continues to tax the full output of the station in spite of the fact that it has steadily grown with the city, until it represents one of the largest composite electric plants in operation. With the view of meeting the demands for light, in the suburbs and outskirts of the city, the company has under consideration the installation of a large alternator equipment designed to supply light and power at a great distance. Situated in approximately

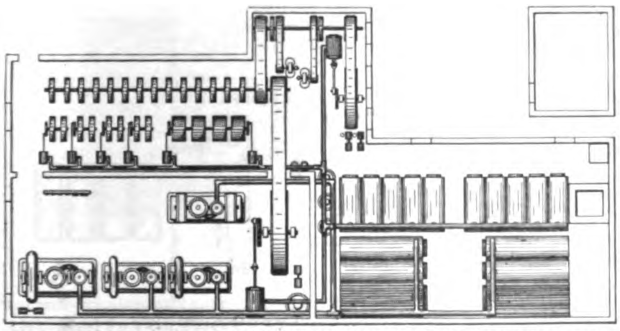

FIG. 2.—GROUND PLAN SHOWING DISTRIBUTION OF BOILERS, ENGINES AND SHAFTING.

the centre of the city, and of the electric railway systems, is the principal steam power equipment, the buildings of which face on Seventh street, between Franklin and Chestnut, convenient to the cars of the Philadelphia & Reading Railroad. From this station nearly 50 miles of electric railroad is dependent for operation, the Reading and Womelsdart line alone being 14 miles in length. Between 15,000 and 20,000 incandescent lamps are maintained, and about 1,000 horse power in motors, located in various establishments where power is required. The arc lights which illuminate Reading's streets are between 500 and 600 in

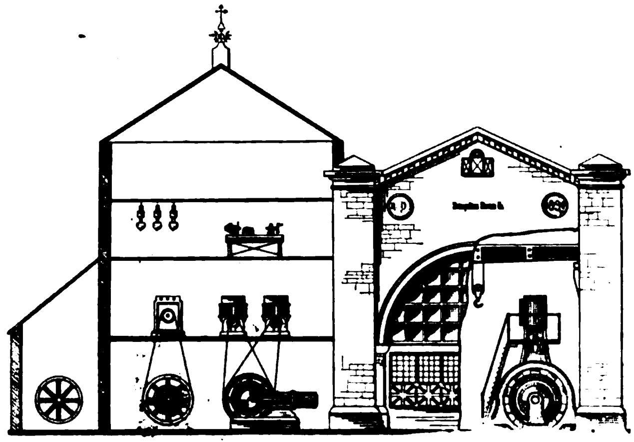

FIG. 3.—SECTIONAL END VIEW, SHOWING OLD AND NEW PORTION OF PLANT.

number, operated from the company's water power plant about three miles below the city on the line of the Reading Railroad. An arc plant of approximately the same capacity is left in reserve at the steam station, having been in service prior to the installation of arc machines at the water power station. It may be of interest before describing the engineering features of these stations, to give a few figures on the cost of light and power in Reading. The arcs are supplied to the city for $105 per year, on a five-year contract. Incandescent lighting is done at the rate of 12 cents per kilowatt, and motors are run for 7½ cents per kilowatt consumption, with a sliding scale of discounts. The earnings of the united plant amount to over $500,000 per annum. The buildings of the Seventh street station are of brick, the new portions having steel girder roofs and concrete floors, being well lighted from above, and allowing ample room for the proper care of the machinery which they cover. A plan view of the Seventh street station can be seen in the second illustration, showing the distribution of the boilers, engines and countershafts, together with the more recently installed direct connected units. The boiler battery is divided into a high and low pressure service, the high pressure steam going to the compound engines of the direct connected units, and the low pressure steam to the

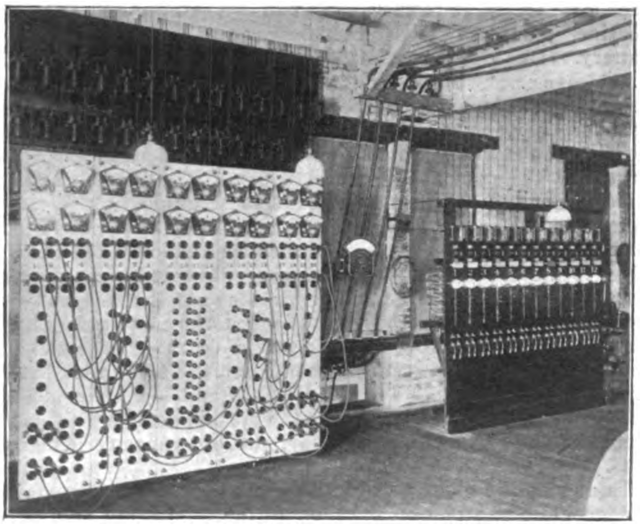

FIG. 4.—BRUSH AND MUNICIPAL SWITCHBOARDS.

high speed belted engines and the simple Corliss. The low pressure battery consists of ten return fire tube boilers of 100 h. p. each, supplying steam at 90 pounds initial pressure. These boilers were built by the Harrisburg Machine & Foundry Co. The high pressure battery consists of six boilers, four of which

are of the return fire tube type, of 150 h. p. each, delivering steam at 150 pounds pressure, built by the Reading Scale & Machine Works, and two "National" water tube boilers of 500 h. p. each, with the same steam pressure of 150 pounds. The piping throughout is of wrought iron, 12 and 14 inches in diameter, 5-16 inch thick, and asbestos covered. No expansion joints are used, the variations in length of the piping being compensated for by means of sweeping copper "ells" at every change of direction. The piping was supplied by Benj. F. Shaw, Wilmington, Del., and the valves by the Fairbank, Pratt & Whit-

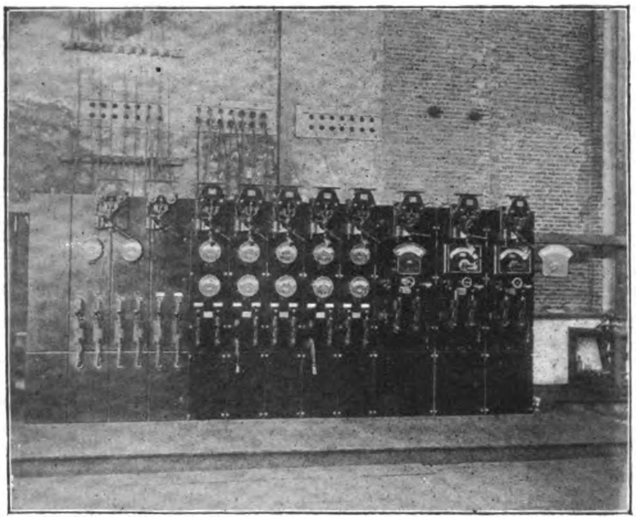

FIG. 5.—RAILWAY AND INCANDESCENT LIGHTING SWITCHBOARD.

ney, and Jenkins Companies. The fuel is anthracite rice coal, mixed with bituminous, one to thirteen, in order to give it life. The price paid for coal by the company is $1.60 per ton, delivered at the boiler house. A brick stack, 125 feet in height, 14 feet square at the base, carries off the products of combustion direct, no economizers being provided. The damper system is that of the Locke Bros., Salem, Mass. The feed water comes from Anteitem Lake and Maiden Creek, and is bought through meters. The combined battery evaporates 2,000,000 gallons of water per month, at a cost of $60. The water from Anteitem Lake contains silica and lime, necessitating the use of boiler precipitating compounds, whereas the water from Maiden Creek contains chiefly vegetable matter. Two horizontal Worthington pumps, each capable of supplying 130 gallons per minute, feed the low pressure battery, and two "Worthington Admiralty Marine" pumps of the same capacity, supply the high pressure battery. This double set of powerful pumps is provided with gate valves, for shutting off the boiler feed, and throwing the supply to fire cocks distributed in efficient places for use in case of emergency. A pressure of 140 pounds may be attained at the nozzles of the hose. This double use of the pumps was introduced by the company's superintendent, Mr. Samuel D. Missimer. Located within a few feet of these pumps is a Westinghouse air compressing equipment, capable of furnishing a continuous blast of air at 75 pounds pressure, which is led through pipes to the dynamo room above, where flexible hose is attached provided with flat nozzles, used for blowing the dirt and dust from the armatures of the various machines. Three large feed water heaters are provided, two being of the "Baragwanath" make, and one of "Berryman" manufacture. The entire battery of boilers is fitted with "Reliance" high and low water alarms. and "Jifferd" injectors. The coal consumption of this boiler plant amounts to 24 tons per day, the bin capacity being 300 tons.

Taking up the older portion of the plant first, with its engines and generators, attention is called to the interesting and rather odd system of countershafts and belts, resultant of a number of changes to the station, and the addition of apparatus. The third illustration accompanying this article, was made to show the ends of these countershafts and their duty on the floor above, together with relation of the new building to the old. Returning to the plan, we find two Corliss engines, directly belted and indirecly belted, respectively, to the long countershaft carrying 14 clutch pulleys. The smaller of these engines, belted to the short intermediate shaft, is of 350 h. p., and is of the Green Corliss type. From this short shaft two 80 k. w., 125 volt, Thomson-Houston incandescent machines are driven, through the medium of clutch wheels. The second Corliss, which is directly belted to the long shaft, is of 700 h. p. capacity, with cylinder 40 by 60, driving a 24 foot wheel, at 60 revolutions per minute. The connection with the countershaft is made by a "Schieren" belt of great weight, which passes through the wall separating the old station from the new, and constitutes a mighty bond between the two sections of the station. The remaining countershafts are independently driven, as shown in the plan, by small high speed engines, revolving the shaft 145 times per minute, against the 285 revolutions of the long shaft driven by the Corliss engines. These high speed engines are of "Ide" manufacture, and are of 150 h. p. each. The friction clutches were made by the Falls Rivet & Machine Co., Cuyahoga Falls, Ohio.

Ascending to the floor above, shown in the sixth illustration, the reserve arc machines and the Edison bipolars are reached. Hand wheels mounted on columns from the floor control the friction clutches below in a most convenient manner. Ten Edison bipolar generators, of 110 volts pressure and 60 k. w. capacity are belted down to the Ide engines, as shown in the third illustration. In addition to these Edison machines, one Edison municipal bipolar generator is installed, wound for 1,200 volts, supplying 500 series lamps for street lighting. It is interesting to note that the switchboard for this municipal machine was originally a 12 circuit arc board, and obtained a first prize at the Philadelphia Electrical Exhibition in 1884. This old board is of slate, and measures 8 by 10 feet, and was reconstructed to meet the requirements of the municipal system, by Mr. Clarence C. Long, the companies' electrical engineer. At present the old board mounts 12 pilot lamps, 12 series of resistances, 12 ammeters, 24 switches and 24 fuses, meeting admirably the conditions for which Mr. Long planned. The ten Edison bipolars of ordinary pattern have their switchboard and controllers in the centre of the group, and are connected on the three-wire system. The arc machines are belted down through the floor to the long countershaft, and are 13 in number. Eleven of these are of "Wood" manufacture, five of 60 light capacity and six of 35 light, the remaining pair being 50 light of Thomson-Houston design. The arc board is of white marble, and is shown in the fourth illustration, with the historical municipal board at the right. This arc board measures 8 by 10 feet, and was built by the Brush Electric Co., according to specifications of Mr. Long. This board has an independent ammeter for each and every circuit, and is protected by 40 Thomson-Houston lighting arresters, located above the board, and shown in the illustration.

The new portion of the station contains the large lighting and railway units, the 3,500 light machine being the first shown in illustration, and the three railway units in the seventh. Two of these railway machines are of 400 k. w. capacity, and one of 800 k. w. These engines are all of the compound type, and were built by the Lake Erie Engineering Co., and are keyed to multipolar railway generators of General Electric manufacture. The frames of these engines are of substantial, heavy duty design, and mount six bearings for each unit, one on either side of each crank, one on either side of the

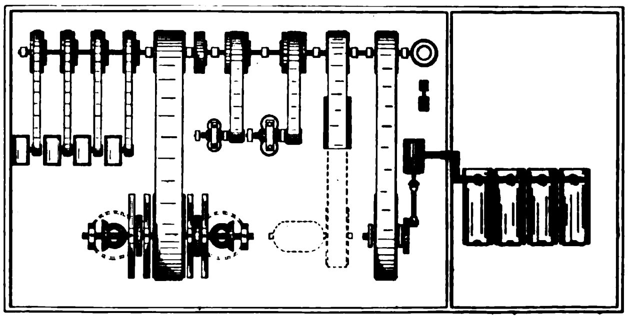

FIG. 8.—PLAN OF COMPANY'S WATER POWER STATION, THREE MILES BELOW READING.
(Showing Auxiliary Steam Plant.)

fly wheel, and one on either side of the generator's armature. The bearings are all water capped, the water being circulated by a Worthington pump, with a capacity of 25 gallons of water per minute. The largest unit has cylinders 22 by 44, with a 36

inch stroke, the normal number of revolutions being 115 per minute. The generators of these engines are wound for 550 volts, but owing to the length of one of the electric roads, the Reading and Womelsdart, through necessity fed from one end, the engines are speeded up until the generators supply the current at 575 volts. The foundation for the largest unit consists of 50,000 hard burned bricks, thoroughly grouted in cement, resting on 18 inches of solid concrete, and capped with an additional six inches of concrete. The two smaller units have the same kind of bed, but made from 35,000 bricks. The fly wheel on the 800 k. w. is 18 feet in diameter, weighs 22 tons, and is mounted on a shaft 18 inches in diameter. All three units are arranged for multiple connection, in response to the demands of heavy traffic due to additional cars, or heavy snow. The lighting unit delivers current at 135 volts pressure, when run at 175 revolutions. The engine carries a heavy fly wheel between the high and low pressure cylinder, and a 100 k. w. generator on each end of the shaft. These generators have double-faced commutators, insuring great life of the machine without repairs made necessary on account of commutator wear. These engines are all run at the present time non-condensing, the exhaust going into the brick stack. Space is left in this building for an additional couple of these machines. The switchboard, shown in the illustration, Fig. 5, is placed opposite the largest unit on the ground floor of the new building. A 20-ton crane is provided, run by hand by means of hanging chains.

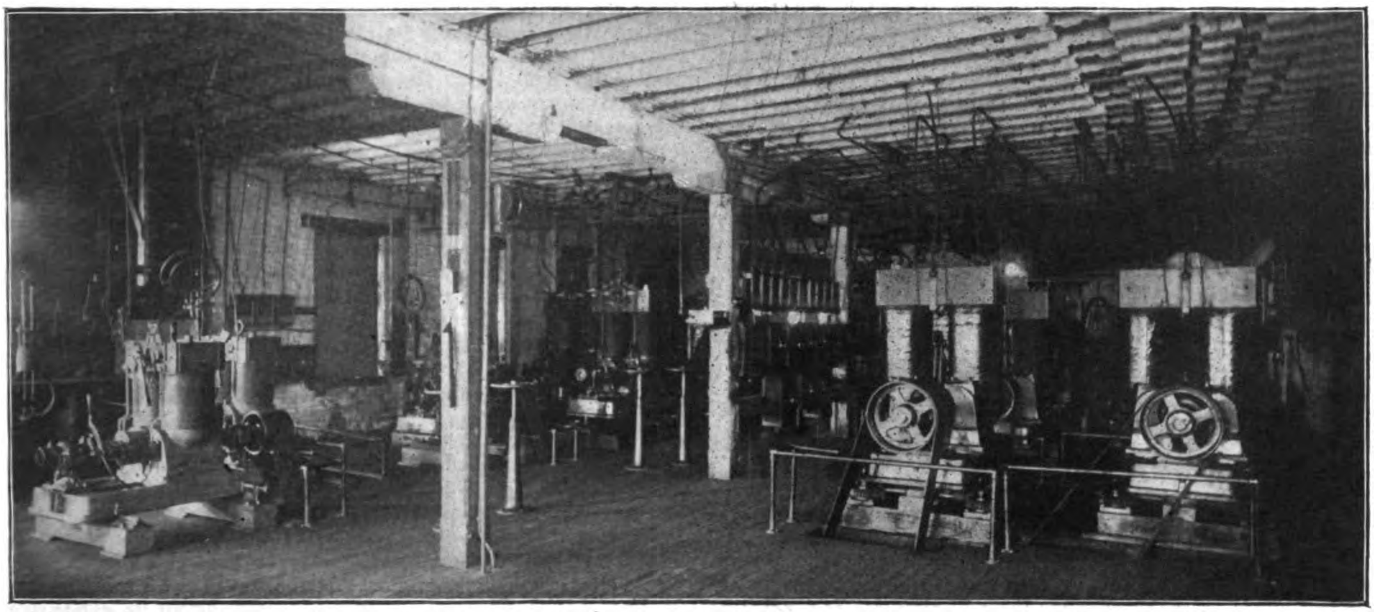

FIG. 6.- RESERVE ARC AND EDISON BIPOLAR MACHINES ON SECOND FLOOR OF OLD PORTION OF PLANT.

The illustration, Fig. 8, is a plan of the company's water plant, known as the "Klapperthal" water power station, although equipped with steam auxiliary, of considerable capacity. The steam portion consists of four 100 h. p. fire tube boilers, built in Reading by the Scott Foundry Co. The engine is a 500 h. p Allis Corliss. The water power is converted into mechanical energy by three wheels. Two of these are upright, 45-inch "Hercules" wheels, acting under an 18 foot head of water, developing 220 h. p. each. They are connected to the large pulley on the main floor as shown in the plan, by means of bevel gears. The third wheel is of "Irwin" manufacture, and is shown under the flooring of the plan in dotted lines. This wheel is

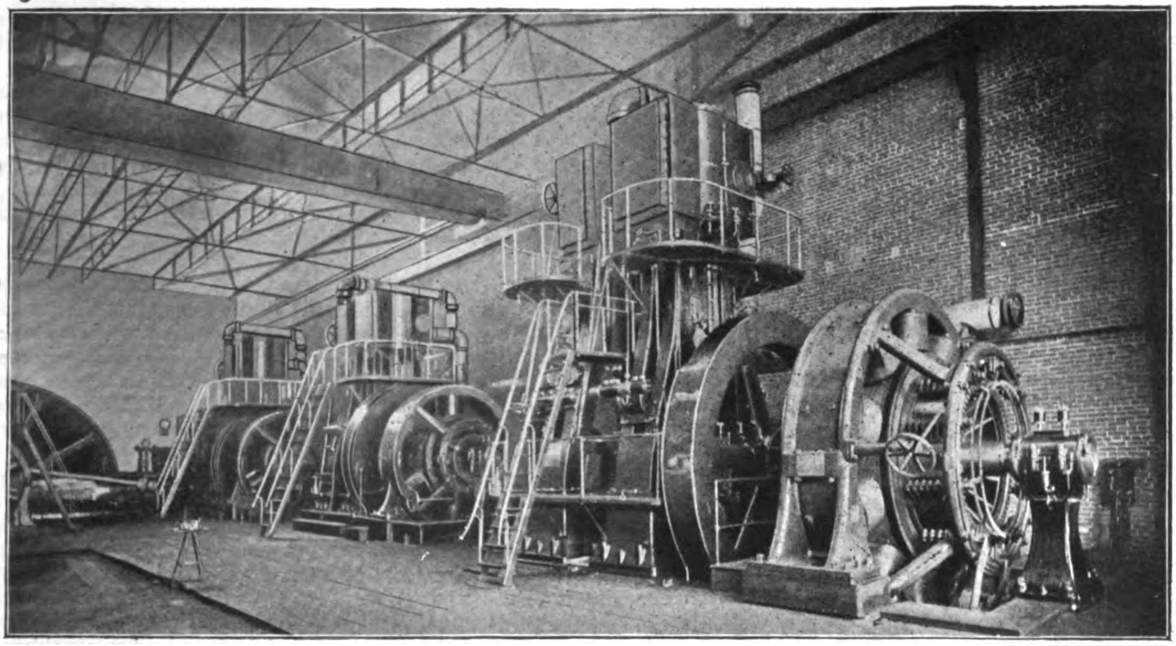

FIG. 7.—RAILWAY GENERATING UNITS.

36 inches in diameter, and develops 250 h. p. The shafting is thoroughly equipped with friction clutches, allowing the instant use of either water or engine power. The generators illustrated in the centre of the plan are 500 volt railway machines, of 200 k. w. and 300 k. w. capacity, respectively. The arc equipment consists of four 125 light Brush machines. The regulation of the water power is effected by the use of electric governors.

The company has for its president, Mr. John A. Rigg, and Mr. K. A. Fichthorn for secretary and treasurer. The directors are Messrs. R. N. Carson, W. R. McIlvain, Geo. H. Valentine, H. C. England, Jas. A. O'Reilly, L. T. Custer, R. L. Jones and R. N. Buckley. Mr. Clarence C. Long is the electrician, and Mr. Samuel D. Missimer superintendent. The writer wishes to express his appreciation of the courtesies and kindness extended to him by Messrs. Long and Missimer, whose thorough familiarity with engineering matters, together with their willingness to furnish data pertaining to the plant which they manage, has been of great assistance in the reporting of this station. Mr. Missimer is well known in Washington, D. C., where, for a number of years, he resided, prior to entering the engineering profession.

The Electric Light Plant in the Small Town—Its Resources and Chances for Extension.

BY J. R. CRAVATH.

I HAVE often seen it stated as an introductory excuse for articles descriptive of electric light plants for small towns that the problems connected with the installation of such plants really required quite a degree of engineering skill and that some little planning was required to get the best results. It is evident that the men who wrote in that way had never been through the trials and tribulations connected with the ownership and management of electric light plants in towns of two to five thousand inhabitants, or they would be aware of the fact that the owners and managers of such plants have more perplexing questions to solve than the officers of the big city companies ever dream of; questions that would be simple enough if the earnings were large and capital readily available for improvements but which under the existing conditions of small earnings are such as to tax the engineering and business ability of the best of men. In this statement I think I have the approval of the several thousand men who are managers and stockholders in plants of the size spoken of.

In this article I do not expect to propose anything radically new. If I did, the manager of the small plant would be justified in reading no further because no small company has any money to spend on experiments. It is simply my idea here to suggest to owners of electric light plants in towns of two to five thousand inhabitants some of the possibilities for increasing business that naturally occur to one who is thoroughly familiar with the conditions existing in many towns of the size mentioned, and who from time to time has been called on to give the matter considerable thought.

A town of the size mentioned usually has an electric light plant, a water works system, a small factory or two, and a dozen or more small steam plants of from one to twenty horse power. Now, there is no good reason why, in the majority of cases, the electric light company cannot supply power to these varied industries cheaper and more satisfactorily than under the present custom of every man for himself. In other words, consolidate the power generation for the community under the roof of the electric light plant; and make the men and boilers and engines there employed earn money twenty-four hours a day instead of two or three. Most men will say in reply to this: "Oh, yes, that's all right for the other fellow, but there's no power business in this town." The writer took occasion to investigate matters once in a town of 4,000 inhabitants, where the manager of the electric light plant expressed similar views. It was found that there were small steam engines in service to the amount of 140 horse power, all dotted around within easy transmission distance of the station. The electric light plant had a maximum winter load of about 175 horse power in arc and incandescent lights. This was not a manufacturing town, but a fair sample of the general run of county seats scattered through the Middle States.

In order to consider this question more intelligently, let us imagine a specific case, taking care that our imagination pictures a set of conditions that prevail in a large number of towns. Take for example a town with a population of 4,500, the heart of a farming district in the Central States. It will have probably a small factory or two, some machine and blacksmith shops, elevators, flour mill, and printing offices, that require power, probably in the aggregate 100 horse power run by small steam engines. The electric light plant if the service is good, the manager energetic and the people are fairly thrifty, will have a load of 40 arc lamps and 120 horse power in incandescents. The incandescents will probably be on the alternating system, and the efficiency of this part of the plant depends very much on the persistency with which the manager has kept small and inefficient transformers off his lines and looked after leaks in insulation on the 1,000-volt primaries. Like every other plant of the kind, it earns money three to four hours a day and loses it the remainder of the time. A few blocks from the electric light plant are the water works, probably owned and operated by the city. Very likely, too, the water supply is taken from a deep well, in which case a most wonderful contrivance known as a deep well steam pump is used. Whatever the supply, it is safe to say that in water works for a town of this size a direct acting steam pump is used. I have never been able to properly appreciate the beauties of the direct acting steam pump except in its smallest sizes; nor have I been able to learn why the designers of the water works plants in our small towns almost invariably put in the most wasteful pumping apparatus they can lay hands on unless it be that they want to give the boiler makers a chance to sell big boilers and the coal dealers a chance to run up as large a yearly bill as possible. The deep well pump found in many small water works is as simple in construction as it is wasteful in operation. The steam piston is directly connected to the pump plunger. Steam is admitted under the piston to raise the load of water and plunger. At the top of the stroke, steam is exhausted at nearly full boiler pressure, and all its expansive power wasted. Two men are employed to run the water works steam plant. Now, it does not require very elaborate reasoning to show that if the electric light plant will put in a power circuit it can afford to bid on pumping the city water by electricity at figures considerably below what the city or water works company can afford to do it for, and that this water works load is a very desirable one for the electric light plant to have; because with the ample standpipe capacity that these water works are provided with, the electric light company can pump the water at whatever hours of the day the light and power load is least and so keep its engines and boilers and men at work on a paying load the whole 24 hours. If the water works have a deep well pump, all that will be necessary to operate it by electric motor will be to counterbalance the weight of the plunger and operate it by a crank geared to an electric motor, and balance wheel. If the supply is not from a well, and direct acting steam pumps are used, it will be necessary to put in double or triple cylinder geared pumps. The steam plant of the water works can be shut down and kept for emergencies, and the two engineers usually hired to keep the water works running can be dispensed with, as all the attendance necessary can be performed by the electric employés.

Taking into consideration the inefficiency of present water works, steam plants and the necessarily high cost of labor per thousand gallons pumped, it is easy to see that there is a chance for the electric light plant to do this work in connection with a power circuit at a fair profit and a reduced cost to the town or water company. It might be said that the electric light plant and water works should on economical grounds be put together in a town of this size, but as the province of this article is to deal with conditions as they usually are, that phase of the question will not be discussed. In most towns they are separate and often the electric light plant is better situated as to coal supply. The important question at issue is how to make the best use of existing plants, as in towns of this size the investment necessary to make any revolutionizing changes is not warranted or at least not forthcoming.

Returning now to our specific case under consideration we find an electric light plant prepared for a maximum load of about 180 horse power. The boiler plant will have, say, three boilers of 75 horse power. The steam engine plant will have probably two engines, both of which are operated to carry the heaviest lighting load, and one of which is run at a very light load from midnight until 6:30 a. m. We have then ample boiler and engine capacity to carry the entire power load of the town for all except about three or four hours in the early part of an evening.

Assuming that there is 100 horse power in small engines in the town, it is not unreasonable to expect that if the rates are low

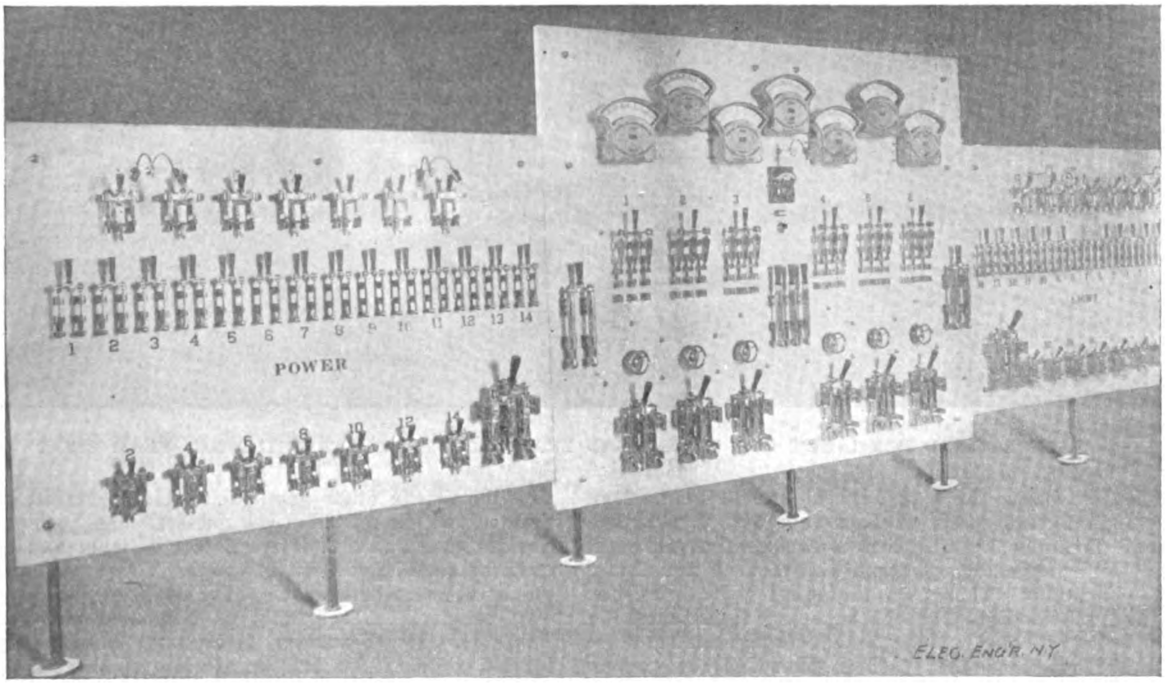
enough, 75 horse power in motor load could be secured, some of which, however, would be intermittent. The securing of the water works pumping work would mean probably 20 to 40 horse power more of power load. The best way to handle this power service would be to put in a 500-volt direct current generator and run a special power circuit around the town. The ideal way might be to put in a two phase alternating system to run power and lights from the same machines and street mains, but this involves the change of all dynamos and transformers, and, as said before, revolutionizing changes cannot be afforded here. Transmission for power at 500 volts direct current involves the least expenditure in such a place, under existing prices, and the service will be practically the same in one case as in the other. The particular arrangement of engines and generators in such a station would necessarily vary with each station, but the general scheme of carrying the load would be somewhat as follows: Going into the plant at noon one would find one engine driving the power generator, the lighting dynamos being out of service. The electric pump at the water works and the other small motors on the power circuit would combine to put a fairly economical load on the engine, probably from 40 to 80 horse power, and one boiler with combustion going on at an economical rate would furnish the steam. When darkness begins to come on, the water works pump can be turned off, and the engine, while continuing to run the power generator for general power supply, has still enough capacity to run an alternator for lighting during the first hour of dusk. At this time the remainder of the machinery in the station will have to be started to take care of the lighting. During the fall and winter, the heaviest load on the plant will be from 5:30 until 6 p. m., when the power load is on and also part of the lights. At 6 o'clock the power generator can be shut down and the boilers and engines made to give their whole output to lighting dynamos, the load on which is a maximum between 6 and 8 o'clock p. m., during December, the heaviest load month. During the evening, as the load falls off, one of the boilers and one of the engines can be shut down, or if necessary the water works pump again started. From midnight until 6 a. m., the time that the plant is operated now at a constant loss, owing to the fact that there is almost no paying load, the engine which drives the alternator can be used to run the power generator to operate the water works pump. At 7 a. m., in the winter the lighting load increases for a brief period, and if necessary the pump can be turned off for a time or more engines and boilers started. From 8 a. m., until noon, the pump and power circuit combine to put a good load on one engine and boiler and still keep the plant earning money.

There is nothing experimental about any of the things proposed. Water works pumps are being operated from electric power circuits and electric light plants are running power circuits. What the writer wishes to emphasize is that in a great many places where electric light companies are doing nothing but lighting, and that at a very small profit, it is possible by combining a power circuit with water works pumping contracts to secure a power load that will considerably increase the earning power of the plant by putting to work machinery and men now employed at a disadvantage because of the few hours per day they are occupied on paying load. There are some places where local conditions will not permit this, but there are many where they will.

There are various engineering details to be thought of in connection with such changes, which I will not discuss here, because each plant presents its own particular problems. Before entering into any such projects the field should be carefully investigated both from a business and from an engineering standpoint. Engineering blunders are usually more serious in small plants in such towns than in large city plants, for in the latter there is possible more reserve machinery and greater earnings to pay for mistakes.

Switchboard for the San Francisco "Examiner" Plant.

THERE is now being installed in the San Francisco Examiner Building in San Francisco, Cal., one of the most complete electric light and power plants in the United States, everything in the building, so far as is possible, being operated by electricity. The accompanying engravings illustrate the switchboard to be used in this installation and we describe it at this time because this switchboard, while intended for use in San Francisco, has been designed and constructed in New York and is now being shipped to San Francisco. In fact, all of the contracts for this plant, with the exception of that for the wiring were taken by local concerns.



SWITCHBOARD FOR LIGHT AND POWER, SAN FRANCISCO EXAMINER BUILDING.—FRONT VIEW.

The board consists of three sections, that on the left being for power, the centre for the generators, and that on the right for lights. It is of polished Italian white marble two inches thick, divided into four panels, one for each end wing and two for the central section. All of the instruments, switches, circuit breakers and other apparatus are mounted directly on the face of the board and, as well as the supporting legs, are finished in polished copper, no nickel or enamel being used, thus giving the board a very rich and finished appearance.

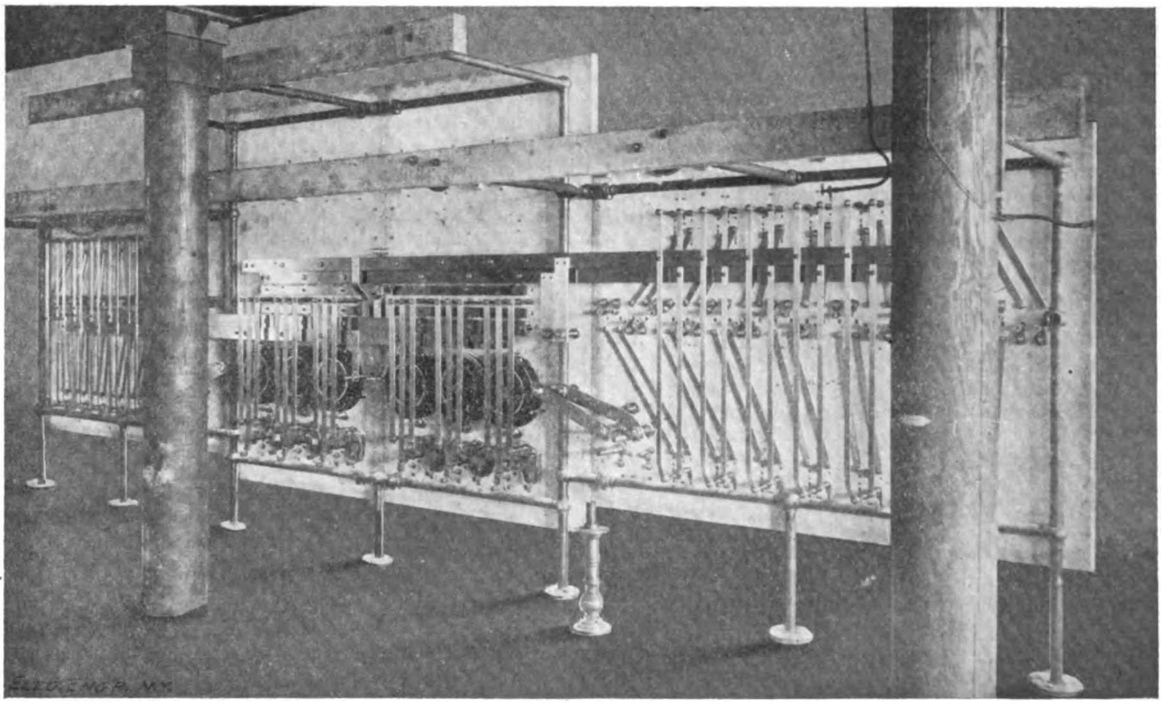
There are fourteen power circuits and fourteen light circuits each controlled by a double jaw double pole Hill switch and a

double pole I. T. E. circuit breaker; no fuses being used upon the board, all circuits being protected by automatic circuit breakers. The power and light circuit breakers are arranged in a double bank above and below the switches and each is numbered to correspond with its appropriate switch. There are two breakdown circuit switches and circuit breakers for connection with separate street service.

On the central section there are six generator circuits each provided with double throw, double pole switches and circuit breakers and one cross connecting switch, so that the power and light busses may be connected together if desired. There are also six handles for controlling the rheostats for the fields of the generators, six ammeters, one voltmeter, one ground detector and one voltmeter switch, all so arranged that the ammeter, main switch, rheostat control and circuit breaker for each generator are in a vertical line one over the other, this avoiding all possible chance for error in manipulation. All of the instruments, switches and circuit breakers are arranged so as to be easily reached by the operator and in such a way that he can operate them with the least possible effort.

The back of the board is finished as perfectly as the front, a noticeable feature being the simplicity of arrangement, there being no complex arrangement of wires and bars crossing one another in all directions, but all being of comparatively straight material and all arranged at right angles to each other and free from all complications. There is a double set of bus-bars, one for power and one for lights, and all necessary interconnecting bars, all of polished copper. The shunts for the ammeter are arranged at the bottom of the board and the field rheostats in the centre. There is also a lighting circuit for illuminating the back of the board.

The whole board is mounted on a supporting frame made of heavy iron pipes united by globe fittings, a construction which is light and strong and admits of great variation in construction. The board is a model of simplicity, practicability and elegance and reflects great credit on its designer, Mr. E. R. Knowles, E. E., who is also the designer and consulting engineer of the Examiner plant, as well as on its constructors, Messrs. Blake and Williams, of this city.



SWITCHBOARD FOR LIGHT AND POWER, SAN FRANCISCO EXAMINER BUILDING.—REAR VIEW.

BOSTON TRAVEL on the suburban steam lines in the last four years is estimated by the State Railroad Board to have decreased about 10 per cent., while the corresponding trolley travel has increased 25 per cent. It runs this way all through New England.

MUNICIPAL AFFAIRS

Municipal Electric Lighting.[1]—III.

BY PROF. JOHN R. COMMONS.

WITH reference to the method of inquiry itself as conducted by the authorities, it must be borne in mind that correspondence and official reports have been mainly relied upon. Mr. Foster, by his own showing, had not personally visited any of the plants concerning which he reports; Mr. Francisco appears to have visited but one of the sixty-four plants tabulated in his pamphlet, and Professor Parsons has apparently visited not more than five or six.

Now, I do not maintain that the correspondence method will fail to give accurate results. It depends upon the care and pertinacity of the investigator. In this respect Professor Parsons excels the other gentlemen. He has taken but little for granted and has made but few guesses. Mr. Foster makes many guesses at the rate of interest, cost of labor and fuel, number of hours burning and candle power. These two writers give the official figures wherever they have obtained them, and then their own estimates subsequently as computed and as printed in Table II. Mr. Francisco gives only occasionally the data for his computations and we are left to infer them from hints vouchsafed here and there. The principal difficulty in the way of securing sound results by correspondence is the impossibility of finding out and weighing the hundred and one local peculiarities which give tone and detail to the enterprise.

These often give a decided turn to the inquiry. Many of them cannot be presented, statistically. For example, the village of Batavia, New York, by providing a council chamber in the building which houses its electrical plant saves $120 in rent each year, equal to $1.20 per arc light. Further, no one can appreciate the sense of relief from the exactions of private corporations and the civic pride and dignity of the citizens who have successfully overcome these exactions unless he visits them, talks with them and learns the history of their movement for municipal ownership.

[1]Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec. Engr.

AGREEMENT AS TO OPERATING EXPENSES.

In attempting to explain the wide discrepancies in these three methods of estimating the cost of municipal lighting we need to divide the cost of production into two parts, operating expenses and fixed charges. Operating expenses are usually stated by the officials of the various cities in the annual reports, and these with the annual output given, make it difficult to arrive at wide discrepancies in estimating the operating costs per lamp.

Table II.
Comparative Estimate of Net Cost to City for Street Lamps—Francisco, Foster, Parsons.

Cities.	Candle Power.	Hours per Year. Francisco.	Hours per Year. Foster.	Cost per lamp hour. Francisco.	Cost per lamp hour. Foster.	Cost per lamp year. Francisco (Computed).	Cost per lamp year. Foster (Computed).	Parsons. Operating Expense.	Parsons. Operating Expense, Interest on Debt, Depreciation 5%.	Computed Interest 4%, and Depreciation 5% on Total Investment.

* Electric works operated in connection with water works
† Profit on entire plant.

This is evidenced in Table I., where the labor costs as given by Parsons and Foster are set side by side. In this item, as well as fuel, repairs and supplies, there is but little opportunity to go behind the returns unless one actually visits the plant and carefully compares item by item the labor, fuel, repairs and supplies actually consumed with that which enters into the published reports. Consequently, we find these two authorities closely agreeing on operating expenses as will be further seen in Table III.

TABLE III.

Fairfield, Iowa	70.39	70.00

Mr. Francisco is an exception to this agreemnet. He vigorously attacks the published reports and discovers malicious attempts to transfer accounts, to misrepresent operating expenses and repairs as new construction, to charge electric light to other departments, and generally to bolster up a rotten business for the benefit of nobody but the politicians. I am unable to follow him in all his figures, as I have not been able to visit the plants whose accounts he criticises. But such evidence as I have been able to get seems to show that he is the wildest sort of a Don Quixote.

Mr. Francisco has also a sliding scale for depreciation. Where he thinks the operating expenses and interest charges of a municipal plant are high and do not need much inflation Mr. Francisco calculates depreciation at five per cent. as in Braintree and Swanton. But when expenses are low and a great cause is at stake, depreciation rises to eight per cent., and so South Norwalk, Detroit and many other places are saved. I mention only those places where he himself states the rate of depreciation. In other cases I am led to infer that it vibrates up and down usually near the eight per cent. pole, by comparing his figures with those of Mr. Foster, who uniformly estimates depreciation at seven and one-half per cent.

Perhaps too much space has been given to Mr. Francisco, but the space seems justified in view of the fact that he is quoted extensively by all who oppose municipal ownership. But the method adopted by Mr. Francisco of comparing the relative efficiency of the two systems on the basis of the candle power per hour furnished for one cent is vitiated by his reckless charges for depreciation and his liberties with the financial reports on operating expenses, as a comparison with Mr. Foster's figures shows in Table II.

BETTER QUALITY OF MUNICIPAL LIGHTING.

It is also to be remembered that there are two qualifications necessary before we can know that the candle power is relatively as great as it appears. These are the quality of the light and the "outages." In every municipal plant, almost without exception, the people of the locality are found on personal inquiry to speak in enthusiastic terms of the superior quality of light they are getting. Unfortunately this field of electric lighting has not been adequately tested, and but few cities, either with public or with private plants, have any record of photometric tests of the efficiency of their lights. The candle power is the "nominal" 2,000 candle power of French standard, which Slingo & Brooker[1] estimate as giving actually only 875 candle power when the current is ten amperes and the voltage fifty, so that this amount of light is produced at a cost of 500 watts. As the usual power varies from 425 to 475 watts per lamp, and municipal officials never as far as I know are provided with photometric appliances, it is within the power of private companies to diminish the candle power below the standard required in their contracts. As long as exact measurements are lacking, we are compelled to depend upon the common opinion of the locality, which is indeed not an accurate judge. This general satisfaction of citizens in their light is one of those local factors which statistics cannot present, but which go far in determining the preference for municipal plants. Dunkirk is given by Francisco as furnishing 718 candle power per hour for one cent, but taking into account the fact that the dynamos there are run at eighteen amperes, and 520 watts are delivered to each lamp, and that the general impressions of citizens and visitors unite in describing them as the brightest lights to be found anywhere in street lighting, it is evident that, in addition to his juggling with costs, his estimate of quality also does injustice to the plant.

[1]Foster gives 132 arcs; Parsons, 210.

LA TEORIA DEI RAGGI ROENTGEN. By Prof. Filippo Re. Palermo, 1898. Alberto Rebers. 64 pages. 6 x 8½ inches. Paper. Price, 60 cents.

The author has undertaken a critical discussion of the various theories propounded to explain the phenomena of the Röntgen rays. This is not intended as a complete or even partial record of work in X-ray experimentation, but the sources of information given by the author supply this purposed omission.

MR. H. B. COX is the subject of an illustrated biographical page article in the March issue of Success. It might be better done, as it is hardly just to Mr. Cox's work and aims, but the matter and cuts are interesting as far as they go.

Vol. XXV. NEW YORK, MARCH 10, 1898. No. 514.

"Made in America."

IN a letter addressed to the "Iron Trade Review," Mr. Andrew Carnegie in a brief but convincing manner shows that a shipyard built in or near New York Harbor and properly equipped and managed ought to be able to compete with any similar establishment in any part of the world. As Mr. Carnegie points out, we can produce steel more than 25 per cent. cheaper than at Glasgow, for example, while as to cost of labor, the most modern appliances, even at higher rates of labor existing here, would reduce this item below that prevailing abroad. Mr. Carnegie is anything but a dreamer, and if confirmation of his proposition be desired, the electrical arts will furnish an excellent example. As to American electric railway apparatus in Europe, that has taken so firm a position that it will be difficult to dislodge our products permanently, if at all, in the future. It may be urged that our experience in electric railway work gave us an advantage of which we have reaped the benefit. Granted for the sake of argument. But how does this explain the continued and increasing shipment of dynamos and motors, circuit breakers, etc., to Europe from our shores? Only recently we were permitted to glance at a list of foreign orders in the works of one of our well known manufacturers,—a list covering page after page of various types of machines and apparatus. But what struck us most was the fact that the machines ordered were not merely for fan motors and the smaller sizes, but ranged all the way up to 60 h. p.! We must confess that the showing surprised us. The meaning of it appears plain when one considers first, the cheapness of our raw material, iron and copper, and secondly the perfection of methods of manufacture, in which machine work is the dominant factor. That this is probably the true solution of the question finds further confirmation in the fact that an able American electrical engineer will shortly leave for Germany to design a line of dynamo electric machinery for a firm in that country, on the American system of manufacture. Reduced to a plain proposition, Europe is still building dynamos, while we have long since manufactured them. We believe that the lead taken by America in this respect will be maintained for a long time to come, while on the other hand, our cheaper raw materials will always give us an advantage which ought to be of a lasting nature.

Mr. O. B. Shallenberger's Work.

COMPARATIVELY few of the large number of electrical engineers and workers now engaged in the electrical field can recall vividly the exact condition of affairs and the state of the art as it existed but a dozen years ago. Up to that period the direct current had held undisputed sway; its main problems had been practically worked out and what improvements have since been introduced have been mostly matters of detail, albeit many of these have left a marked impress on the art. But with the introduction of alternating current work in the United States, there dawned a new era of development entirely distinct in many respects from that which had preceded it. We need hardly recall the bitter controversies and discussions carried on under the generic head of "Direct vs. Alternating Current," which were waged with great energy on the part of the respective adherents of the two causes,—controversies, indeed, the echoes of which are still heard from time to time, though growing fainter at each reverberation. One of the greatest objections urged at the time against the alternating current was the absence of a meter to record the consumption of current. This was, in truth, a serious objection as even at that time the flat rate basis of charge was recognized to be a make-shift arrangement conducive to waste of current, and open to other not less serious fault finding. The demand for an alternating current meter was urgent, and indeed it may be said that its practical accomplishment was of paramount importance to the success of the alternating current industry. We believe that the honor and credit for the first successful meter of this type will be generally conceded to belong to the late Mr. O. B. Shallenberger. Seizing upon a phenomenon accidentally observed, he made it the basis of one of the most beautiful as well as one of the most accurate instruments known in the field of existing electrical measuring apparatus. The record of Mr. Shallenberger's work, the salient features of which are given on another page, proves him to have been a high type of the American inventor, and one who beautified everything he touched. The mere fact that after ten years of practical use the Shallenberger meter of to-day is practically the same instrument that it was when introduced is proof sufficient of its inventor's thorough grasp of principles and their industrial application. "Si monumentum quaeris, circumspice," was never more truly applied than to the inventor just gone from among us. His memory will always live in the annals of electrical work as a pioneer of true genius, one who by his sunny nature and imaginative turn of mind always suggested to those who knew him intimately that relationship between true poet and true inventor which lies under the surface of mere worldly and commercial considerations. The data now presented is but one leaf out of the life book of one who died all too young and all too soon. We desire to acknowledge our indebtedness for this material to the Westinghouse Electric Manufacturing Company, which has hastened to contribute to our columns this memorial of a career spent so loyally and brilliantly in its service.

The Single Phase Induction Motor.

THE polyphase induction motor has met with such rapid introduction in commercial practice, due to the success of long distance transmissions, that it has rather crowded into the background its single phase prototype. We do not propose here to enter upon a discussion of the relative merits of these two types, merely recording the prevailing opinion of those entitled to speak with authority, that the polyphase motor possesses advantages distinctly its own. But the fact that single phase stations constitute as yet the large majority of the work-

ing installations both here and abroad and bid fair to continue as such for an indefinite period in the future, makes it eminently desirable to bring to as high a state of perfection as possible motors adapted for the current furnished by them. For this reason, if for no other, the able and scholarly paper read by Mr. C. P. Steinmetz before the American Institute of Electrical Engineers, on February 23, will be welcomed by all who still regard with hope the future of the single phase motor.

The first portion of Mr. Steinmetz's paper deals with the load and speed curves of the single phase induction motor, and tells us that the motor will not start from rest, but when started in either direction will accelerate with increasing torque and approach to synchronism; that the speed is much more constant in the single phase induction motor than in the polyphase motor. Also that the maximum torque and output of the single phase motor are somewhat greater than those of the three-phase motor per circuit. The second portion deals with single phase induction motor starting devices; and all the methods devised for this purpose are divided into three classes, namely: 1. Phase splitting devices; 2. Inductive devices; and 3. Monocyclic starting devices. These three methods are then discussed in detail and undergo a thorough mathematical treatment, emerging at last with a verdict in favor of the last named, which most nearly reproduces in starting and accelerating the conditions of the polyphase motor.

Unfortunately the paper was but briefly discussed by a number of experts, who seemed to agree, that even admitting the saving of wire attending the use of the single phase induction motor, as well as its high efficiency and no-sparking quality, the low power factor and difficulty of regulation of the motor will prevent it from superseding the polyphase motor in the near future. Mr. Steinmetz's mastery of the subject is unquestioned, and his thorough investigations and exhaustive presentation of this difficult problem entitle him to the gratitude of the profession, but it appears that the subject is sadly in need of a Faradic treatment before it can be brought within the reach of the mental faculties of the average electrical engineer of to-day. But as in the case of the direct current motor, time will serve to crystallize and clarify the theories which now seem so involved to many.

An Electrical Corps for Our Army and Navy.

THE recent organization of the Corps of Electrical Engineers in England and the activity in our own army and navy circles subsequent to the terrible disaster to the Maine has reminded us forcibly of the lack of electrical training of our militia, and recalls the timely warning of Lieut. B. A. Fiske, U. S. N., who over seven years ago advocated the formation of an electrical corps. There is an old German proverb which says that "After the child has fallen into the well they think about covering it up," and similarly finding ourselves ill prepared for a sudden emergency, people are now urging the formation of the much needed electrical corps. Lieut. Fiske in his very able address before the New York Electrical Society in 1890, on "The Civilian Electrician in Modern War," showed by giving a résumé of the manifold uses of the electric current on warships and in fortifications, that electricity has come into use as one of the great factors in warfare, both on sea and shore, not as an adjunct, such as for lighting ships and forts, but as a vital element in the handling of weapons in actual battle and in the construction of new instruments which accomplish things heretofore impossible. Such a corps, he held, could be formed under existing laws, and there would be no difficulty in enlisting members. The qualifications as regards education and intelligence would be greater than those for any other regiment, corps or battalion. Its military and naval usefulness would be acknowledged, and its position in all respects would be one of dignity. The whole electrical influence of New York and of the country would be at its back, and there is no reason why it should not acquire a worthy national fame. We strongly recommend the immediate formation of such a corps of electrically trained army and navy engineers, who would be of invaluable service to our country in time of war. An ounce of prevention is better than a pound of cure.

In this connection our little article on the electrical equipment of the Maine will be of interest. It sums up the work done on shipboard, and shows how large a factor electricity is. Very few uses of electricity are overlooked. Yet strange enough, as was pointed out the other day, thermostats are not included, and we are informed that the hand thermometer prevails. It will be noted that electrical conductors are not run near the magazines.

Telephone "Extortion."

AT the present moment there is a "crusade" in Washington, just as there is in New York, against the local telephone company, by certain persons, but it is based on grounds which are more or less ill chosen. For example, a Dr. R. Kingsman complains of treatment in the Washington "Star" and tells his case. He had a patient whose condition alarmed him, so that he rushed to the nearest telephone station, where, not being known, he informed the operator who he was. Having no small change he could not drop his ten cents in the slot and "was forced to stop long enough to get a bill changed. The latter was the most annoying part as the circumstances were desperate." The doctor asks us to imagine his feelings, and to judge the company accordingly. How foolish! We can all imagine his feelings, but why think harsh things of the innocent company or its operator? The doctor might be in a hurry to take a car or mail a letter, or hire a messenger, but he would have to split his ten dollar bill or his gold coin, and he alone would be to blame for not providing himself with small pieces of money. If he were to try large bills on the New York elevated or street cars, he would run great risk of being bounced, whether the city or private company owned the roads. His deficiency of small coin at a critical moment was very unfortunate, but proves nothing against any company. It is surprising, on the contrary, that such a puerile complaint should come from an educated, professional man. His story reminds us of the doctor out in one of the middle States, who owns some telephone lines of his own and who will not allow any other medical man to use them for professional calls. We hardly know which is the more unreasonable of the two men.

A Novel Convention Plan.

ONE of the most interesting and attractive plans we have ever seen suggested for a convention is that of Mr. J. M. Hill, of Chicago, in behalf of the Northwestern Electrical Association. The idea is to hold the convention on one of the fine steamers plying between Chicago and Duluth, two or three days being spent thus on Lake Superior, and the remainder of the week at Duluth, points of interest being taken in on the way, such as Sault Ste. Marie, the Calumet and Hecla copper mines, Mackinac, etc. It will be remembered that the National Electric Light Association is to meet in Chicago, June 7, 8 and 9; and at the end of that week Mr. Hill proposes that ship shall be taken for Duluth, filling in a second week. A warm welcome awaits at Duluth, and there is, of course, much of interest to be seen there and at the City of Superior.

This is a bold scheme, with attractive features, and if the lakes are calm it ought to be a delightful trip. Probably some of our readers will hardly care to indulge in the three weeks' absence from home and business that it involves, but others may be glad to avail themselves of such an opportunity for seeing the Great Northwest at the beginning of another era of prosperity. Mr. Hill proposes that the beautiful steamer "Northwest" shall be engaged forthwith, and that half-a-dozen notable electricians shall be invited as guests. There is nothing half-way or half-hearted about his plan, and if it is carried out, successful excursion convention methods will have been notably increased.

TELEPHONY AND TELEGRAPHY

The New Telephone Exchange Building, Brooklyn, N. Y.

THE New York and New Jersey Telephone Company enter this month upon the occupancy of their handsome new building, corner of Willoughby and Lawrence, Brooklyn, a most central location. For the present the central exchange will not be transferred, but the offices will at once be concentrated in the new headquarters. When the conditions and preparations are ripe, the exchange transfer will also be made. This new building, one of the finest in the Borough of Brooklyn, is eight stories and basement: The first and second stories are of dark blue Indiana limestone, thence upward the constituent masonry is of pearl gray brick and terra cotta. The building is of the strongest material. The inner foundation supports are massive blocks of heavy concrete, upon which rest systems of heavy iron beams, constituting a grillage base, sustaining steel posts, extending to the roof. The floor construction is divided to best advantage beween hollow, fireproof flat arches and the Columbian fireproof system. Throughout, the interior building work is of the modern steel frame construction.

The most modern plumbing and heating methods go to the

NEW EXCHANGE OF THE NEW YORK AND NEW JERSEY TELEPHONE COMPANY.

equipment, and the protection against destructive conflagration guaranteed by the structural materials is supplemented by effective fire-fighting apparatus, including two hydrants within reach of the fire department, with water capacity for over-reaching not only the roof of the telephone building itself, but the roofs of other buildings within a block of it in any direction.

On the first floor of the buliding will be the supply department, on the second, the repair shop, while on the fourth will be the office of the general superintendent; on the fifth that of the general manager; on the sixth, the office of the treasurer; on the seventh, that of the auditor, while the eighth floor will be the operating room, where there will be one of the largest switchboards in the country.

The New York and New Jersey Telephone Company, whose charter covers Long Island, Staten Island and the northern half of New Jersey, when organized in 1883, and for five years thereafter, had its offices at 397 Fulton street, but since 1888 they have been at 16 Smith street. In its first year, it had thirty central exchanges, and 2,339 subscribers all told, 1,656 of whom were in Brooklyn. At the present time the company has thirteen exchanges in Brooklyn, 18,500 subscribers on Long Island, eighty-six central offices, and a service in every town and village throughout the Island. The service places the subscriber in connection with 40,000 stations in and around Brooklyn and 200,000 throughout the United States.

The New York and New Jersey Telephone Company, which stands in the forefront among the telephone enterprises of this country by reason of the magnitude of its operations, may congratulate itself upon its achievement, not only for what it has done for its subscribers, in giving them an admirable service, but also on the splendid structure it has reared, which may be said to properly represent the character of the enterprise.

The officers of the company are: President, Charles F. Cutler; vice-president and general manager, W. D. Sargent; secretary, Joel C. Clark; treasurer, Henry Sanger Snow; executive committee, Charles F. Cutler, W. D. Sargent, Joseph P. Davis and Joel C. Clark. The board of directors consists of Charles F. Cutler, Alexander Cameron, Joseph P. Davis, Charles A. Nichols, Hugh Kinnard, William D. Sargent, David B. Powell, George H. Prentiss, Joel C. Clark, Felix Campbell, Edward J. Hall and Henry Sanger Snow.

The Telephone Business In Cincinnati.

The annual report of General Manager G. N. Stone of the Cincinnati Telephone Co. shows what work has been accomplished by the company during the past year, and also gives some statistics of considerable interest. No service, except possibly that rendered by the United States Postal Department, which was operated at a loss to the Government, of $8,127,088.44 in 1896, and $11,411,779.65 in 1897, approximates in convenience and cheapness that represented by the business handled by this company, at an average cost to its patrons of only a fraction less than one cent per message, including answers thereto. Many of the subscribers use their telephones more than one hundred times per day, which reduces the cost to them to so small a fraction of one cent per message that it cannot be estimated. The company's business has been highly satisfactory. Many extensions and additions have been made and many new exchange subscribers gained. Toll lines have been extended, local pole lines reconstructed, and underground subways extended.

Making a comparison with the number of exchange subscribers, it is found that within the past ten years the list of subscribers has increased from 3,110 to 5,281. Of the entire number of exchange subscribers 4,285 are connected by copper metallic circuits, equipped with long distance instruments. The record of exchange messages kept during the past year shows the company has made for its exchange subscribers within the Cincinnati exchange district 25,510,752 connections, or an average of 17 calls per day per subscriber. This company now has 258 miles of poles and 1,238 miles of wire in use in its toll line system in the States of Ohio, Indiana and Kentucky. The number of toll and extra-territorial messages handled during the year 1897 was 160,504; during the year 1896 was 140,973, an increase of 19,531. Average number of toll messages per day, 440. The total mileage of wires is 6,910 miles and 490 poles. There are 299,310 feet of underground cable, containing 5,353 miles of conductors in pairs.

Government Telephony For Washington Public Buildings.

In the U. S. Senate at Washington on March 3, Mr. Butler (Pop., N. C.,) introduced an amendment to the District of Columbia Appropriation bill, appropriating $100,000 to be used by the Postmaster General to establish and equip a modern telephone system among the public offices and buildings in the district. The idea is to have a complete exchange system for the public departments, quite independent, it is said, of the regular Bell exchange now serving the district.

Hearing the Children's Prayers By Telephone.

During the early part of a dinner recently given in Washington, the guest of honor, a young married woman who is the proud mother of two very small boys, suddenly paused, with a startled look, in the midst of an animated conversation with her host, and cried: "There, if I didn't forget those boys again! Have you a telephone in the house, and may I use it?" Her host conducted her to the telephone, and presently she returned.

"I do hope you will pardon me," she said; "but you see, I always have Georgie and Eddie say their prayers to me before they go to sleep. In the hurry of getting off, I forgot it tonight, so I have just called up their nurse. She brought the children to the telephone, and they have just said their prayers over the wire, so my mind is relieved."—Argonaut.

Bell Telephone Output.

The American Bell Telephone Company's monthly statement of output of instruments for the month ended Feb. 20 shows:

	1898.	1897.		
Gross output	25,897	19,680	Inc.	6,217
Returned	12,790	8,015	Inc.	4,775
Net output	13,107	11,665	Inc.	1,442
From Dec. 21 to Feb. 20:				
Gross output	51,758	34,117	Inc.	17,641
Net output	28,927	19,701	Inc.	9,226
Outstanding	949,620	791,990	Inc.	157,630

SOUTHERN BELL TELEPHONE COMPANY has recognized in a substantial manner the fidelity of its employés who stood by the posts during the recent yellow fever epidemic.

An Artesian Lighting and Power Plant.

FRED. DONALDSON, YANKTON, S. D.

SIX years ago I decided to sink an artesian well upon my premises for the purpose of grinding feed, sawing wood, ripping lumber, etc., and after it was completed, I found I had power enough to operate a small dynamo. The artesian power being a steady power I did not need the regular appliances used with the dynamo, but simply a voltmeter. I run thirty-five lights with my machine, which light my residence, barn, and place of business, and all this after the machinery was installed costs me about 20 cents a month for electric lights; this cost is for oil.

A few months ago I decided to build a grain elevator, and in this I also placed an electric motor, which furnishes the power to run the elevator and grain cleaning appliances. I run my machinery by the artesian well. The diameter of the pipe is 4½ inches and is 525 feet deep. I have hydrants about my premises and in case of fire, I have 200 feet of 2½-inch hose and I can throw water in a solid stream 100 feet. The power is derived from an undershot water wheel. All I have to do when I want to run my elevator, electric lights, or any of my machinery is to turn a wheel which controls the water, and away she goes. I may add that the dynamo and motor were built by the Sioux City Electrical Company, and have always worked admirably.

Electricity For Turret Turning On American Men-of-War.

IN view of the recent attention directed to naval affairs, it is interesting to note the great superiority which electricity gives over steam, pneumatic and hydraulic power for the extremely important service of turning and controlling the turrets on the battleships which carry with them the guns. A severe comparative test of the steam controlled turret and the electrically controlled turret was made upon the Brooklyn in 1896 by a committee appointed for the purpose, which committee reported to the Secretary of the Navy the result of their test.

In order to test the machinery under the most unfavorable conditions likely to be experienced in service, the ship was heeled to starboard the greatest angle of heel that could be obtained by any means available, and the guns were run out.

For the purpose of testing the degree of accuracy with which the guns could be pointed, at any desired object, distant objects were selected upon which the guns were trained. It was found that the electrically controlled turrets could be turned through any arc, within the limits of the train, and brought to rest with the object previously selected between the cross hairs of the sighting telescope with great facility, the controller being readily worked with the operator's eye at the telescope and the turret having a smooth and regular motion. While it was possible to arrive at the same result with the steam-turned turret, it was only done with considerable difficulty, owing to the fact that the controlling lever cannot be worked with sufficient facility with the eye of the operator at the sighting telescope, and on account of the jerky movement of the turret. The committee reported that the control of the movements of the turrets given by the electrical mechanism was ample and thoroughly satisfactory while the steam mechanism was not so.

The electrical control was that invented by Mr. H. Ward Leonard and is popularly known as the "Ward Leonard System of Control." As a result of the above mentioned test and the extremely favorable performance of the electrically controlled turrets on the Brooklyn, during its visit to England for the Queen's Jubilee, it was strongly urged that the electric mechanism be installed upon the battle ships Kentucky, Kearsarge and Wisconsin. After a long discussion of the matter and further reports to the Secretary of the Navy, the Ward Leonard system of control was finally adopted for the Kearsarge, Kentucky and Wisconsin and is now being installed upon them.

MR. H. S. JACOBS, a prominent mining engineer, is interested in the project of establishing a large electrical power plant in the vicinity of the City of Mexico. He has just returned from the State of Morelos, where he went to look up the subject. He states that he located a place where 25,000 h. p. can be obtained. It is in the Amacuzac river, sixty-five miles from the City of Mexico. The wires would have to be brought to the City of Mexico over the hills, and he is positive that he could deliver 5,000 to 8,000 h. p. He estimates that the plant would cost $2,000,000 Mexican money. It is stated that the electric lighting plant and many small manufacturing concerns have agreed to take power from the proposed plant as soon as it is placed in operation.

Trolley Freight In Massachusetts.

Several of the Massachusetts trolley companies have petitioned for permission to do an express business, and even carry freight. In some instances, the bill presented to the legislature contains a provision that the case shall be submitted to the people of the municipalities traversed. The Northampton Street Railway, which has had a provision for a two-thirds' popular vote to that effect, comes in with a petition to reduce two-thirds to a majority. It has held one referendum and failed to get the two-thirds. Officers in other places who believe that they can get the two-thirds, do not object to it, but prefer to have the whole business done in the legislature, without submission to the people. In one of the bills a provision was inserted for carrying goods to the weight of 100 pounds, and the vice-president of the road said that they expected to stop their cars at houses by the roadside long enough to take off these parcels. It was testified that the Northampton road has carried crates of strawberries, a quarter of beef, and a barrel of flour. A bill was heard for a general law, but it was strongly opposed by corporation interests. There is a feeling that the progress of the times demands that larger powers be given to street railways in respect to express packages.

Electric Fork for Footpads.

An inventive genius in Media, Pa., has rigged up a device which he confidently predicts will put an end to street car holdups. He is a conductor on an electric line, and has lined the interior of his car with wires charged with electricity. Along these wires runs a small trolley device, which is intended to be kept in his hand constantly, no matter where he may be in the car. It terminates in a fork-shaped metallic rod, and with this rod it is proposed to electrocute any daring footpad who attacks the car.

MECHANICAL

The Hunt Coal Cracker.

THE growing demand for and rapid introduction of automatic stokers to be used under boilers of large steam generating plants, have necessitated the coal to be furnished broken up sufficiently small for feeding it through these modern labor and money saving devices. The Hunt Coal Cracker, illustrated and described below, has been designed for breaking the large

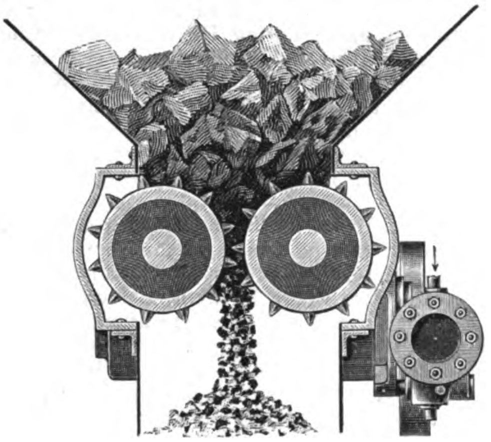

FIG. 1.—HUNT COAL CRACKER, VERTICAL SECTION.

lumps in run of mine of bituminous coal into smaller pieces for the above mentioned purpose. It is believed by many engineers who use hand firing, both in stationary and in locomotive boilers, that it is advantageous to break the larger lumps of coal into smaller sizes, both on account of the easier and more perfect distribution of the coal on the grates by the fireman and a more perfect combustion resulting from an evener fire. The points on the rolls are made of tool steel with hardened points, especially designed to crack and not to crush the lumps of coal so that none of the advantages of lump coal are lost. The fine coal passes through the rolls unaltered.

Figs. 2 and 3 show the cracker driven by a direct connected steam engine having the steam ports and passages all draining continuously downward, the steam entering at the top of the cylinder and the exhaust passing out at the bottom, so that all condensed water is immediately drained off, and every drop of the water from cylinder condensation is swept out of both the cylinder and ports at each stroke of the piston, thus materially

The rolls are made the proper diameter to break the coal to the size required, and are not adjustable in the frame, thus eliminating all elements that might be sources of weaknesses and

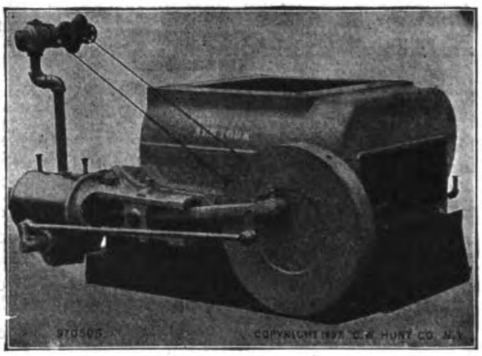

FIG. 2.—HUNT COAL CRACKER, DRIVEN BY DIRECT CONNECTED STEAM ENGINE.

delays. Both the gearing and the rolls are entirely enclosed, each in a separate compartment in a cast-iron frame. This prevents the coal dust from entering either the bearings of the machinery, the gear box, or the room in which the breaker is

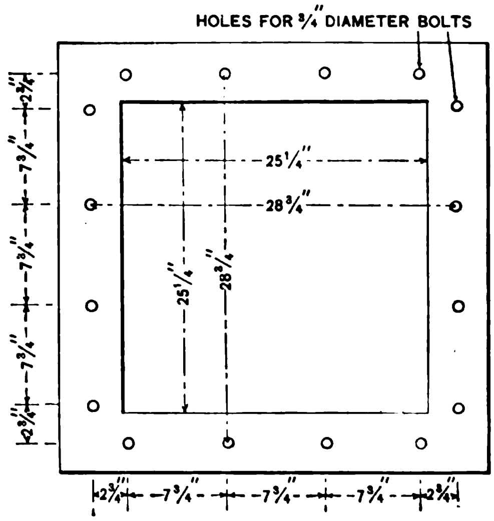

FIG. 4.—LOCATION OF HOLES IN TOP AND BOTTOM FLANGES OF HUNT COAL CRACKER.

located. The gearing is easily accessible, but entirely inclosed and protected from dust while running. The gearing runs in a bath of oil that insures perfect lubrication. The vertical distance between the feeding hopper and the delivery spout is reduced to

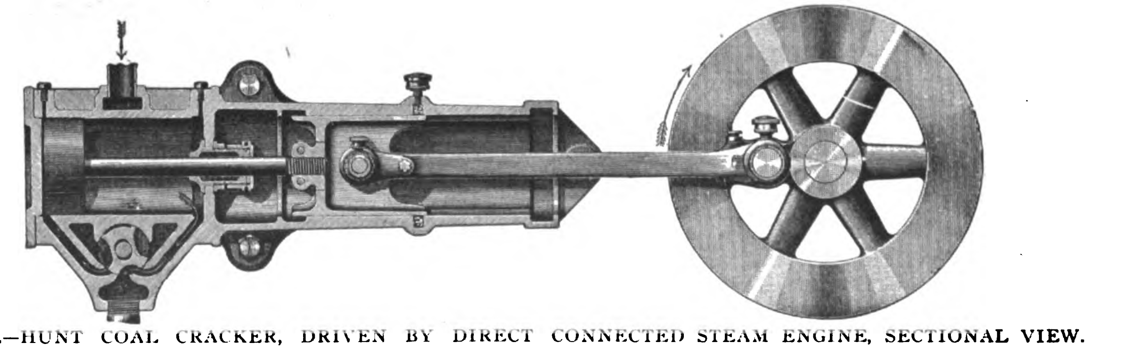

FIG. 3.—HUNT COAL CRACKER, DRIVEN BY DIRECT CONNECTED STEAM ENGINE, SECTIONAL VIEW.

reducing the cylinder condensation. In starting there are no pockets of water to plunge forward and endanger the engine. There is no danger from frost even in zero weather.

The cross-head bearing on the slide is made longer than the stroke of the piston (see Fig. 3), so that it will not uncover a central oil well, packed with an elastic absorbent packing, that keeps the sliding surfaces constantly swabbed with oil. The bearing is unusually wide, so that the bearing on the slide is about four times the area generally used in commercial engines.

a minimum as the space available for the cracker is usually limited. A horizontal spindle governor is adjusted in position and so located as not to interfere with the feeding hopper. The breaker may be placed below the hopper under the railway car track so that the coal feeds directly from the car through the rolls into a conveyer which transports it to the storage bins. When coal is hoisted from a vessel the breaker is usually put under the hopper into which the coal buckets dump.

Fig. 4 shows the exact distance of the bolt holes in both the

top and the bottom flanges of the cracker, which are given here in order that engineers can design and construct the coal hoppers and spouts that will fit the cracker when ordered. The cracker can be bolted directly underneath the lower part of the hopper, or supported on the top of the spout or in any other manner that may be convenient.

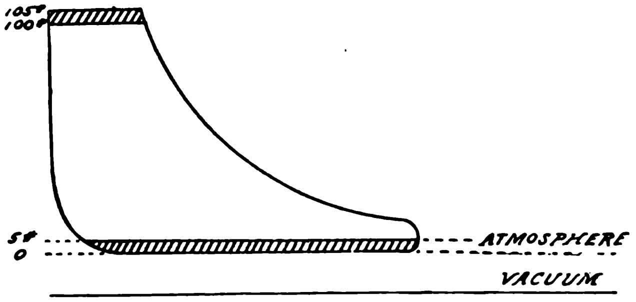
While the average horse power consumed by a coal breaker is small, the necessity for strong and perfect construction of the parts under stress must be evident. The axles in the rolls are of steel, 4⅜ inches in diameter, and the frame is of massive construction to resist the great and sudden strains that may come upon it especially when some foreign substance accidentally falls in the rolls while running. These machines can be used to advantage for breaking other hard substances, the rolls in such cases being made to suit the work. The breaker is self-contained and ready to run when placed in position, thus saving the framing and erecting expenses frequently required with machinery that is not so complete in itself. The breakers are either in stock or in process of construction, and a prompt delivery can be made for standard sizes that break the coal to suit automatic stokers or hand firing. The usual sizes have the rolls 1½ inches, 2½ inches or 3½ inches apart. Rolls will be made to order for other sizes. An electric motor or power from ordinary shafting can be used instead of the steam engine shown in the engravings. The shipping weight is about 7,000 pounds.

Exhaust Steam Heating.

BY GEO. L. THAYER.

THE controversy which has been running in the columns of The Electrical Engineer for the last two months has become interesting from the fact that it has drawn into the discussion some gentlemen who as advocates of two patented systems of steam heating have endeavored to throw all the fog possible upon the question. In plain English it is the "back pressure" versus the "vacuum" systems, the question at issue being the loss of power due to carrying a back pressure of several pounds upon the engine and whether it can be overcome by a corresponding increase in boiler pressure.

Mr. I. H. B., evidently of Lockport, N. Y., throws "theory" to the winds and rests his case upon the statements of the station engineer as to the effect of back pressure upon engine economy. Under actual working conditions for reasons which will be shown later the difference in coal consumption may not be five per cent. either way. On a margin as small as this it is impossible to determine the difference except by an actual test. In an electric light plant it is only during the hour of heavy load that excessive back pressure would cut any figure. The



amount of exhaust is usually greater than the heating system can absorb and part of it will be exhausted into the air. During the hours of light load live steam will have to be supplied to make up for the deficiency, and the amount of back pressure carried will not affect the amount of coal consumed except that due to the increased condensation in the radiators due to the higher temperature of the exhaust steam.

Let us take up the matter of raising the boiler pressure an amount equal to the back pressure carried. Assume the conditions as follows, when the engine is exhausting into the atmosphere.

Boiler pressure	100 pounds.
Point of cut-off	¼.
Back pressure	5 pounds.

Referring to the diagram, the lower shaded area is the area of the indicator card which is cut off when the engine is working under five pounds back pressure. The upper shaded area is that added by increasing the boiler pressure five pounds. As the cut-off occurs at one-fourth the upper shaded area extends only quarter of the way across the diagram, while the lower one extends almost across. Consequently the power developed by the engine at a given cut-off is not regained by increasing the boiler pressure by an amount equal to the back pressure. When working at one-fourth cut-off the boiler pressure must be increased approximately four pounds for each pound of back pressure added. If the boiler pressure cannot be increased the capacity of the engine is reduced and in electric lighting at the very time that the capacity is most needed. But as the cut-off comes later in the stroke the necessary increase in boiler pressure is not so great. At one-half cut-off it requires but double the amount of back pressure to get the same power. If the engine is a compound the maximum cut-off will not be much greater than one-third and the engine capacity suffers accordingly.

The question of the effect of back pressure upon the economy is an entirely different matter. Within the range of reasonable back pressures the amount carried makes no difference in the economy of the engine as long as the demand for exhaust steam is greater than the supply. Possibly an engine builder might make some slight modifications so as to obtain the best compression curve under the new conditions. When, however, the supply of exhaust is greater than the heating system can absorb then the heat wasted is the amount necessary to raise the steam escaping into the air from atmospheric pressure to that of the back pressure carried. With a back pressure of five pounds, steam at 100 pounds, and feed water at 212 degrees, the loss is 18 per cent. of the steam escaping through the exhaust head. This high percentage comes from the fact that the heat necessary to raise one pound of steam from boiling point to say 5 pounds pressure will raise 4.8 pounds through the same range at 100 pounds pressure. At 12 pounds back pressure the loss becomes 25 per cent., and at 31 pounds it becomes 50 per cent. This loss is not as serious as would seem at first thought for not only is it a small portion of the steam generated but the loss will only occur a few hours a day. The cutting down of the reserve capacity of the plant is a far more important thing, for the lighting load comes in the heating season.

In all gravity or back pressure systems an increase of back pressure is a distinct gain in the working of the heating apparatus. The air in the pipes is more thoroughly driven out, radiators heat up quicker, give off slightly more heat, and things work better all around. In central station work, unless the distances are excessive, the back pressure ought not to exceed five pounds except possibly in the coldest weather. When it much exceeds this amount the heating system is likely to prove a serious drag upon the station.

NEWS AND NOTES

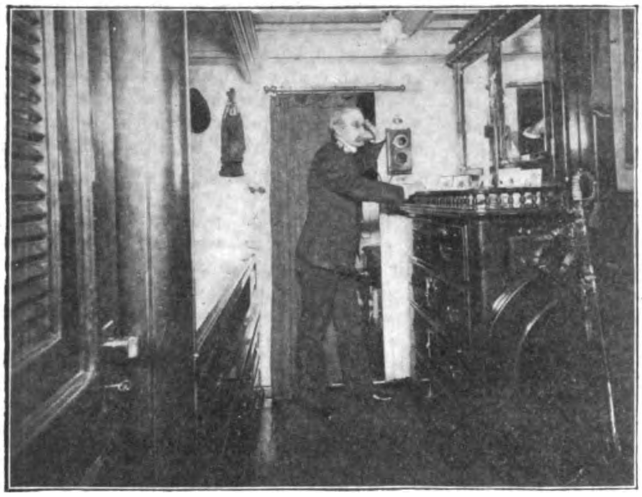
The Electrical Equipment of the Maine.

AT the Bureau of Electrical Equipment of the Navy Department, at Washington, the following facts of interest to electrical engineers, regarding the steam and electrical equipment of the ill-fated battleship "Maine," sunk at Havana, have been obtained. It will be remembered that one suggestion from the Spanish Government to explain the accident, was that the electric light steam plant had exploded. Of this there is said to be absolutely no proof. There were two dynamos and engines directly connected and secured to the same bed plate. The bed plates were made as light as practicable, consistent with necessary strength and rigidity, and had suitable provision for securing tachometers and for catching the waste oil.

The engines were two-cylinder, double-acting, not compounded, and vertical, and were directly connected to the armature shafts by means of flexible couplings, and were capable of driving them at a speed of 500 revolutions per minute when the dynamos were generating their maximum output. The initial steam pressure was 60 pounds; exhaust, either atmospheric or vacuum. The engines were fitted with the most efficient kind of lubricating devices and guards to catch flying oil.

The dynamos were compound wound and self-regulating, producing with 500 revolutions of the armature per minute an electromotive force of 80 volts. Under these conditions each dynamo had a capacity of 25 amperes, and within these limits there was only a variation of 1½ per cent. in speed to produce the required e. m. f. The dynamos were connected to a switchboard from which all of the circuits for incandescent lamps and motors were supplied, and the motors and incandescent lamps could be operated at the same time. A ground detector and two direct reading voltmeters were supplied with the plant. There was no single wire larger than No. 14 B. W. G. used in the wiring, and it had to conform to the naval standards in such cases. The incandescent lamps were arranged in six sections from the switchboard (main). There were three electric motors installed on board, with an aggregate of four horse power. Each motor was directly connected to a countershaft and had a constant speed of 150 revolutions per minute, and were self-regulating and reversible.

There were electrical telegraphs with dials in each engine room and connected to transmitters in the conning tower and in the chart house (or on the bridge), whereby the number of engine revolutions desired could be easily transmitted. These



CAPT. SIGSBEE AT THE TELEPHONE IN HIS QUARTERS ON THE U. S. MAN-OF-WAR MAINE, SUNK IN HAVANA HARBOR.

telegraphs were so constructed that messages could be repeated back from the engine room. There were telegraphs of the same character with repeating dials at all steering wheels and steering engine and connected in the same manner as the engine room instruments, and were so constructed that at all stations the angle was indicated at the same moment. A direct reading rudder transmitter showed the angle of the rudder with the keel and was connected with dials placed on the bridge at the steering engine and in the conning tower. This angle was shown at all stations at the same instant. There were also heeling indicators to show the angle of heel and the angle of roll and were located in the chart house and two other places on the upper deck. The dials of all the telegraphs and indicators were lighted by electricity and the necessary energy was supplied for the instruments from the dynamo circuits. There was a reserve battery for use in case the dynamos were not in operation.

There were in all 237 16 c. p., 151 10 c. p., and 10 32 c. p. incandescent lamps, or a total of 398 lamps; 279 junction boxes, 33 cut-outs, 126 receptacles, 63 switches, and 380 switches. In addition to these there were two large searchlights, one fore and one aft. There were thirty-three voice pipes or telephones on board the ship, eleven buzzers, two bells, two gongs, an automatic water alarm circuit, and twelve 10-inch clockwork alarm gongs with electrical escapements.

Our illustration shows the gallant commander of the "Maine," Captain Sigsbee, using the telephone, located in his apartments on the ship. To remove the suspicion that the explosion might have been caused by defective electrical construction it may be stated that none of the wires was allowed to run near the magazines where the explosives were kept.

Society & Club Notes

American Street Railway Association.

The seventeenth annual convention of the above association will be held at Boston, Mass., on Tuesday, Sept. 6, 1898, continuing in session four days. The exposition, which has always been so important a part of the conventions in the past, will be held in the Massachusetts Charitable Mechanics Association Hall, the largest exposition hall in the country. There will be 60,000 feet of floor space with all the heat, light and power desired. The headquarters of the association will be at the Hotel Brunswick, and the railroads will sell tickets on the certificate plan. All communications should be addressed to T. C. Pennington, Secretary, Chicago City Railway Company, Chicago, Ill.

German Association for Acetylene and Calcium Carbide.

The German Association for Acetylene and Calcium Carbide will hold an exhibition of the recent progress that has been made in this industry, and at the same time a congress to consider the various scientific and practical questions that have arisen in connection with it. The exhibition, which will be held in Berlin from March 6 to March 20, will comprise acetylene generators, lamps, purifiers, and mixing apparatus, acetylene burners, motors, and soldering tools, calcium carbides, electric furnaces, and electrodes, and the different varieties of machinery used in the manufacture of the calcium carbide. Rigorous regulations have been adopted by the Berlin police to prevent any premature explosions, and no generating apparatus using more than about one-half pound of the calcium carbide will be permitted in the main exhibition hall. The use of pure compressed or liquefied acetylene gas will be prohibited, and a limit of 120 pounds pressure has been placed on mixtures of the gas. The use of acetylene gas for illumination is increasing, and the coming exhibition will show how general its application can be made as well as the simplicity with which the gas is generated.

Uses of The Kelvin Quadrant Electrometer.

AT a regular meeting of the Royal Society held on Jan. 27, 1898, Dr. J. Hopkinson, F. R. S., communicated two very exhaustive and interesting papers by Mr. Ernest Wilson. The title of the first paper was "The Kelvin Quadrant Electrometer as a Wattmeter and Voltmeter." The author proves the verification of Clerk Maxwell's formula, that the deflection of the needle of a quadrant electrometer should vary as $(A-B)\left(C-\frac{A+B}{2}\right)$ where C is the potential of the needle, and A and B the potentials of the two pairs of quadrants. The methods of procedure and results of the test were presented in detail by a number of diagrams, curves and tables. The author arrives at the conclusion that the Kelvin quadrant electrometer can be used with accuracy as a wattmeter in the case of alternate currents having any phase relation, and that, as pointed out by Dr. J. Hopkinson, it is necessary to see that within the range of potentials applied, Maxwell's formula is verified. This is, perhaps, best done by applying steady potential differences to the needle and quadrants, and measuring these by Poggendorff's method, employing Clark's standard cell as the unit of comparison. It could also be tested by applying known alternating potentials to the needle and quadrants, the curves being in phase. If it is required to use alternating potentials of high value, such, for instance, as 2,000 volts or more, a suitable transformer could be employed to reduce the potential on the needle. Such unloaded transformer could have the primary and secondary electromotive forces in phase, and of the same wave form, so that no error would be thereby introduced.

The title of the second paper by the same author was "The Magnetic Properties of Almost Pure Iron." Some interesting hysteresis curves are presented in this paper and the author made a thorough investigation of the apparent magnetic instability of the specimens under test. Regarding this property he makes

the following statement: It has already been nцticed, and is well known, that if the magnetizing force be varied from one maximum value through zero to a value equal, say, to the then coercive force of the material, that tapping the specimen will produce a considerable change of induction; or, if the observed kick on a ballistic galvanometer (in circuit with a secondary coil wound on the specimen) due to such change be added to the observed kick when the magnetizing force is raised to the opposite maximum, the sum does not equal the whole kick which would be observed if the force were at once varied from the one maximum to the other. During the interval the magnetism appears to continue to settle down, so that the change which lastly takes place is not so great as it would be if such apparent settling down did not occur.

ELECTRICAL EXHIBITION. FROM MAY-2 TO MAY-31-

Details of The Telegraphic Tournament.

WITH regard to the telegraphic tournament to be held at the Madison Square Garden during the Electrical Exhibition in May, the Telegraph Age announces that the events so far arranged will include:

A message class for receivers, transmission thirty minutes, receivers to use typewriters of their selection.

Novice class, open to persons not having an official record; sending five minutes.

Championship class, open to all, sending five minutes, with prizes for receivers.

Ladies' class, free for all, sending five minutes.

Two-forty-word class, open to those not having an official record of 240 words or better, sending five minutes.

Two-thirty-five-word class, open to all who have not an official record of 235 words or better, sending five minutes.

Two-thirty-word class, open to all who have not an official record of 230 words or better, sending five minutes.

Two-twenty-five-word class, open to all who have not an official record of 225 words or better, sending five minutes.

An entrance fee of $2 will be charged.

Mr. James D. Reid has been asked to present the prizes to the winners. Mr. Thos. A. Edison is taking great interest in this tournament, as he always does in such affairs, and he will make a phonographic record of the best transmissions, noting the exact time of the revolution of the machine so that perfect reproductions can be made at any future time. The contestants will thus be enabled to have an exact record of their own work, which they can listen to whenever they feel so disposed.

Among the judges proposed for the telegraph events are: J. H. Bunnell, telegraph supplies, and an old-time telegrapher; E. A. Leslie, president of an electric light company, and an old-time telegrapher; A. S. Brown, electrical engineer of the Western Union Telegraph Company; A. E. Sink, manager of the Western Union Telegraph Company, 195 Broadway, New York; Francis W. Jones, electrical engineer of the Postal Telegraph-Cable Company; Geo. H. Usher, superintendent of the Postal Telegraph-Cable Company, New York; E. H. Cox, manager of the Associated Press, New York; Thos. J. Smith, electrical supplies, and an old-time telegrapher, and Thos. R. Taltavall, editor of the Electrical World; and as judges of the typewriting contest, Chas. W. Price, editor of the Electrical Review; T. C. Martin, editor of The Electrical Engineer; W. D. Weaver, editor of the American Electrician; J. B. Taltavall, of Telegraph Age, and E. W. H. Cogley, assistant superintendent of telegraphs of the Associated Press, New York.

Those wishing to communicate with Mr. Fred. Catlin, the manager of the tournament, can do so by addressing him, care of Post Office box 2403, New York.

INTERNATIONAL TYPAL TELEGRAPH COMPANY has been formed at Detroit by W. F. Jarvis, T. S. Jerome and W. H. Flynn, with a capital stock of $10,000.

REPORTS OF COMPANIES

New Orleans Traction Co.

The annual exhibit of earnings and expenses is as follows:

	1896.	1897.
Gross earnings	$1,334,276.52	$1,239,256.04
Operating expenses	748,547.77	847,842.86
Net earnings	$585,728.75	$391,423.18
Decrease for 1897		$194,305.57

The operating expenses of the electric lines, which were 55.81 per cent. in 1896, were 68.40 per cent. in 1897. The total operating expenses which were 56.1 per cent. in 1896, were 68.40 per cent. in 1897. The year's fixed charges and other deductions left a net deficit of $80,741.65, against a surplus of $68,448.37 in 1896. The number of passengers carried was 23,998,216, against 25,969,538 in 1896. The net earnings per car mile were 4.29 cents, against 6.35 cents in 1896. The yellow fever epidemic, now past, is responsible for the poor showing of 1897, but the January showing is a remarkably good one.

THE STOCK MARKET

Harping On Cuba.

There can be no question as to the disturbing effect of Cuban affairs on the American market, but it is not so extreme as supposed. For example, last week, while some sixteen railroad securities went down about one point, twenty advanced. It was pretty much the same way all along the line,—erratic but in general wonderfully steady. The present week may see a change, depending on the course of affairs, but it is by no means certain that a declaration of war would send prices lower. The stimulus to trade and transportation of a big extra demand for all manner of supplies might send them up. During last week, on sales of 22,683 shares, Western Union opened at 86⅝ and closed at 86¾. General Electric on sales of 12,270 shares opened at 32 and closed at 31¾. On sales of 850 shares, American Bell Telephone began the week at 251 and closed at 262. Speaking of trade as a whole, Bradstreets says: "Nearly all signs point to an unprecedented volume of business being done or arranged for at the present time."

Copper is up again, being now 11.87½ cents. Steel rail, heavy, is steady at $18.

PATENT NOTES.

Field Rheostats Having Separable Steps.

A patent was issued Feb. 8, 1898, to H. Ward Leonard the claims of which relate to field rheostats in which the insertion of resistance causes a reduction in the current strength, and in which the resistance is composed of separable unit steps and carried by a common support. Mr. Leonard says: "Such rheostats have been placed upon the market by two different concerns. Neither of these concerns are licensed under my patent, and I propose to promptly institute suit against infringers. In addition to the present patent I am the owner of several other patents, the claims of which are also infringed by the field rheostats of the other manufacturers referred to."

A typical claim in the patent issued Feb. 8 to Mr. Leonard which is No. 598,568 is as follows: "Claim No. 3. A rheostat having in combination a number of separable resistance steps, each step of resistance being of practically the same size and design and the ohms of a series of the steps being tapered progressively and a common support for the steps of the resistance, substantially as set forth."

INVENTORS' RECORD

Classified Digest of U. S. Electrical Patents Issued March 1, 1898.

Alarms and Signals:—

APPARATUS FOR VISIBLE SIGNALING. L. Sellner, Vienna, Austria-Hungary, 599,742. Filed March 28, 1896. Relates to improvements in apparatus for visible signaling, more particularly for use at night and in localities, such as ships, the position of which is liable to be changed.

Batteries, Secondary:—

PLATE FOR ACCUMULATORS. W. Majert, Grunau, Germany, 599,-718. Filed August 19, 1897. Comprises the plate or bar having corrugations therein of the shape of the half of a cone when divided on the line of its axis.

Conductors, Conduits and Insulators:—

PNEUMATIC TRAVELER FOR PIPES OR CONDUITS. L. C. Kohler, Milwaukee, Wis., 599,713. Filed June 16, 1897. Adapted under pneumatic pressure to travel through a pipe drawing with it a cord.

FLEXIBLE ELECTRIC CONDUCTORS. A. Bournonville, Philadelphia, Pa., 600,058. Filed November 20, 1897. Improvement in the manufacture of flexible conductors, such as telephone cords.

STRAIN INSULATOR. H. Carmichael, Malden, Mass., 600,063. Filed June 13, 1895. Consists of interlocking metallic members, an interposed body of insulating material incompressible at the temperature and tension of use specified, an enveloping mass of insulating material compressible at the temperature and tension of use, and an inclosing jacket for the compressible insulating material.

TELEGRAPH CABLE. J. J. Hall, Slough, Eng., 600,073. Filed Oct. 4, 1897. Consists of a plurality of conductors each provided with a wrapping of a netted textile fabric secured thereon by a spirally wound textile thread or yarn, the conductors being laid in a bunch in the form of a cable, and a textile cord wound spirally around the whole.

Distribution:—

TRANSFORMATION OF ALTERNATING CURRENTS INTO DIRECT CURRENTS. A. Muller, Hagen, Germany, 599,789. Filed July 30, 1897. An electroreceptive device capable of generating a counter electromotive force substantially equal to the electromotive force of the alternating current.

SYSTEM OF ELECTRICAL DISTRIBUTION. B. G. Lamme, Pittsburg, Pa., 599,943. Filed September 18, 1897. Means for varying the electromotive force of a circuit or feeder automatically in proportion to load.

Dynamos and Motors:

ELECTRIC MOTOR. O. H. Pieper and A. F. Pieper, Rochester, N. Y., 599,791. Filed October 17, 1896. Improved circuit arrangement and switches whereby sparking at the switch is prevented when the current from a line is cut off.

ALTERNATING CURRENT MOTOR. W. Stanley, Pittsfield, Mass., 599,810. Filed May 9, 1896. Relates to a novel type of induction-motor to be operated by phase-differing alternating currents. It is constructed with a single primary element of field magnet structure and a single secondary core wound with closed coils.

VARIPOLAR MOTOR OR DYNAMO. H. H. Wait, Chicago, Ill., 599,815. Filed August 20, 1896. A double set of armature windings connected with separate commutators which are in connection with a switch adapted to connect the windings either in series or parallel to vary the range of the speed of the motor, while by a continued movement of the switch the effective poles of the fields may be varied in number to produce the same result.

ELECTRIC MOTOR. E. McNerney, Pittsfield, Mass., 599,913. Filed May 22, 1897. Reciprocating electric motor.

NON-SYNCHRONOUS ELECTRIC MOTOR. B. G. Lamme, Pittsburg, Pa., 599,940. Filed April 30, 1894. A form of winding for the primary members of rotary field motors which, when supplied with multiphase currents, will produce a rotating field that closely approximates in effect a single pole of uniform strength mechanically rotated.

DIRECT CURRENT ELECTRIC MACHINE. B. G. Lamme, Pittsburg, Pa., 599,941. Filed May 8, 1896. Has field magnets with inwardly projecting pole pieces provided with relatively narrow magnetic pole-shoes which project laterally from the pole-faces and serve to increase the width of the fringe of the magnetic field.

INDUCTOR MOTOR. B. G. Lamme, Pittsburg, Pa., 599,942. Filed July 12, 1897. A magnetizing-coil provided with a magnetic circuit having a relatively wide air-gap and a relatively narrow air-gap, in combination with a set of generating coils adjacent to the wide air-gap.

CURRENT COLLECTOR FOR DYNAMO ELECTRIC MACHINES. G. W. Nell, Philadelphia, Pa., 600,088. Filed February 23, 1897. Intended to overcome the objections which are incident to the commutators and brushes now generally employed in connection with this class of machinery.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. E. P. Warner and H. H. Wait, Chicago, Ill., 599,818. Filed March 16, 1897. Consists of a chimney of insulating material by which the lamp is supported. Ducts therein adapted to receive and protect the feed rod and the conductors leading to the lamp, and a hood adapted to protect the insulating chimney from moisture.

ELECTRIC ARC LAMP. C. Tepel, Bennett, Pa., 599,880. Filed December 31, 1896. An arc lamp provided with an electro-magnet feeding mechanism and a vertically movable slotted tubular holder for the upper carbon, in combination with a mechanical feeding mechanism provided with a slotted tubular holder for the lower carbon, and a positive differential feed, whereby the arc is maintained at the one point.

INCANDESCENT ELECTRIC LAMP. J. T. Lister, Cleveland, Ohio, 599,910. Filed October 2, 1897. Comprises a single lamp bulb with two filaments with means for connecting either filament separately with the lamp circuit through the circuit contacts.

ELECTRIC ARC LAMP. H. P. Davis, Pittsburg, and F. Conrad, Wilkinsburg, Pa., 599,931, Filed August 22, 1896. A feeding and brake mechanism for arc lamps, comprising a supporting-frame, a feed wheel and chain, and a brake wheel geared to the feed wheel.

PORTABLE ELECTRIC LAMP. L. Paget, New York, 599,975. Filed July 8, 1897. Type of portable electric lamp which utilizes batteries as the source of current supply,, such, for instance, as are used in connection with hand lamps or lanterns, bicycles, carriages, and analogous vehicles.

Miscellaneous:—

ELECTRICALLY OPERATED HOISTING MACHINERY. A. J. Shaw, Muskegon, Mich., 600,092. Filed May 6, 1893. An arrangement of electrical circuits and connections as applied to hoisting machinery, and particularly as related to a traveling bridge crane.

Railways and Appliances:—

COLLECTING CURRENT DEVICE. L. Gutmann, Peoria, Ill., 599,-781. Filed April 26, 1897. The combination with a body portion of gauze conductor, of a strip of insulating material, and a superposed stratum of conducting material electrically connected with the gauze at one extremity of the brush.

PNEUMATIC CONTROLLING MECHANISM FOR ELECTRIC RAILWAY CARS. S. H. Short, Cleveland, Ohio, 599,807. Filed November 13, 1897. A system wherein one or more cars throughout the train are equipped with controlling and braking apparatus and may be operated independently when detached from the train or in co-operation with the other cars when connected up in a train.

ELECTRIC RAILWAY. W. M. Brown, Johnstown, Pa., 599,828. Filed October 7, 1897. A traveling magnetic closer having a compound winding comprising a winding receiving a shunt-current from the main circuit, and a second winding receiving a current from the main circuit only when the current is passing to the motors, in combination with an independent source of current supply and means for passing current therefrom through the second winding when the main circuit falls abnormally.

ELECTRIC CAR TROLLEY. W. H. Russell, Newcastle, Canada, 599,-868. Filed April 18, 1896. A trolley wheel bearing that shall make the wheel less liable to be thrown off the trolley wire.

MAGNETIC CLOSER. J. N. Thomas, Johnstown, Pa., 599,881. Filed October 19, 1897. Magnets of that type which are carried by electric vehicles to actuate a current conveyer placed between the bared working conductor and the source of supply.

ELECTRICALLY PROPELLED VEHICLE. P. R. Salberg, Pittsburg, Pa., 599,947. Filed February 5, 1896. Mechanism for operating and controlling railway cars intended for heavy traffic and to be run at high speeds.

SUPPLY SYSTEM FOR ELECTRIC RAILWAYS. D. Urquhart and F. Wynne, London, Eng., 600,101. Filed February 25, 1897. System of wiring for surface contact electric railways.

THIRD RAIL. L. M. Maxham, Boston, Mass., 600,009. Filed June 7, 1897. Electric conductors for railways in which the conductor being located upon the roadbed it is desired to insulate the same from all possible contact with the people or animals crossing the track.

Regulation:—

METHOD OF AND MEANS FOR CONTROLLING ELECTRIC MOTORS. S. H. Short, Cleveland, Ohio, 599,804. Filed May 19, 1897. Consists in maintaining a substantially constant or uniform accelerating current until the desired speed has been attained, and thereafter reducing the current thereby maintaining a uniform speed.

METHOD OF AND MEANS FOR CONTROLLING ELECTRIC MOTORS. S. H. Short, Cleveland, Ohio, 599,805. Filed May 19, 1897. Similar to above.

METHOD OF AND MEANS FOR CONTROLLING ELECTRIC MOTORS. S. H. Short, Cleveland, Ohio, 599,806. Filed May 19, 1897. Similar to No. 599,805.

ELECTRIC REGULATOR FOR DYNAMOS. W. H. Chapman, Portland, Me., 599,892. Filed February 10, 1897. A solenoid having a movable iron core, and composed of four distinct coils of wire arranged to oppose each other and to balance each other's magnetic and mechanical action on the core, and to thereby neutralize each other's effects whenever an even number of them is in action, and to pull the core one way or the other when an odd number of them is in action.

METHOD OF AND APPARATUS FOR REGULATING ELECTRIC MOTORS. B. Frankenfield and D. C. Jackson, Madison, Wis., 599,-932. Filed January 28, 1897. Method of varying the speed of a multipolar motor, which consists in weakening and strengthening the magneto-motive force due to the coil exciting one or more of the poles, while leaving the magneto-motive force due to the coils exciting one or more of the poles unchanged.

Switches, Cut-Outs, Rheostats, Etc.:—

ELECTRIC SWITCH. G. Doyle, Brookline, Mass., 599,692. Filed August 14, 1896. Details of construction.

RHEOSTAT. S. H. Short, Cleveland, Ohio, 599,803. Filed May 14, 1897. Consists of a spider having radial arms adapted to receive the resistance material in spiral convolute layers between them, and means for attaching the motor-circuit terminals to such resistance material.

ELECTRIC CONTACT DEVICE. J. L. Buchanan, Johnstown, Pa., 599,891. Filed February 4, 1897. A frame and a plurality of laterally movable rollers carried thereby and having flanges extending completely over the conductor.

QUICK BREAK SWITCH. H. P. Davis, Pittsburg, Pa., 599,929. Filed July 22, 1897. Comprises two stationary jaw-terminals having laterally yielding resilient sides.

SWITCH FOR ELECTRIC CIRCUITS. H. P. Davis, Pittsburg, Pa., and E. F. Harder, Wilkinsburg, Pa., 599,930. Filed October 28, 1896. Consists of a stationary jaw-terminal and a movable blade having spring plates or washers riveted to its sides, the outer side faces of which make contact with the stationary jaw-terminal.

SWITCH FOR ELECTRIC CIRCUITS. G. Wright, Wilkinsburg, Pa., 599,954. Filed September 18, 1897. A double throw switch, comprising stationary socket terminals, co-operating plungers and a pivoted operating-lever having arms provided with cams for engaging and actuating the plungers alternately in opposite directions.

CENTRIFUGAL RESISTANCE CONTROLLING DEVICE. G. H. Whittingham, Baltimore, Md., 600,051. Filed July 29, 1897. Comprises a revoluble head; resistance coils arranged in circles thereon; a pivoted switch-arm also on the head, and a centrifugally-operated lever connected with the switch-arm.

ELECTRIC SWITCH. J. J. Flint, Denver, Colo., 600,112. Filed Feb. 16, 1897. Details of construction.

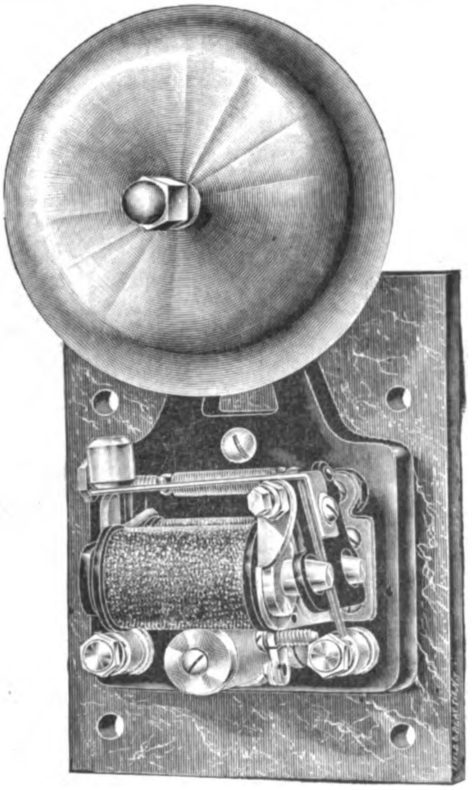
Telephones:—

TELEPHONE TRANSMITTER. J. H. Rogers, Bladensburg, Md., 599,867. Filed March 9, 1897. Consists of a fixed electrode, a movable electrode mounted thereon, and an elastic conical sounding board or target depending from the movable electrode.

TRADE NOTES & NOVELTIES

High Tension Current Bells.

MESSRS. EDWARDS & CO., of 144th street and Fourth avenue, New York, have lately put on the market gongs for use on electric light circuits. The cut illustrates their well known "Vigilant" bell, arranged for this class of work. Any of their bells, either electric or electro mechanical can be furnished to meet the same conditions. This style of bell is mounted on a marbleized slate base and arranged to operate on



"VIGILANT" HIGH TENSION CURRENT BELL.

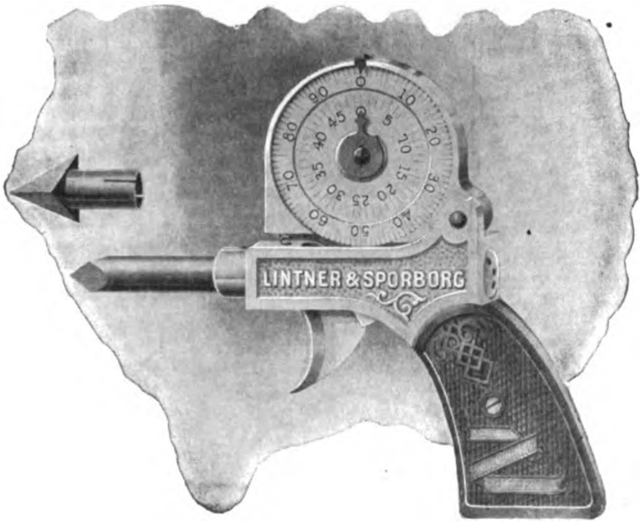
currents up to 500 volts. The new feature of this article is the use of a special resistance substance, which will neither melt nor burn, which is placed in the circuit of the bell. The armature being attracted, shunts the coils of the magnet, leaving the resistance in the circuit so that there is no sparking and the contacts cannot burn out. It is very economical as at no time can more than one-sixth of an ampere pass through the bell.

The Bullock Electric Manufacturing Co.

In about two weeks the Bullock Electric Manufacturing Company will begin the erection of its new plant at Norwood, Ohio, about four miles from Cincinnati. The contract for the steel structural work has been let and bids are now being received on engines, boilers, etc. This plant will consist of large machine shops (300 x 100), brass foundry, pattern and office buildings and power house, and will have a capacity of four or five times the present Bullock plant. The company is now ordering many new machine tools and their shop will contain the finest machinery in the market, as well as the latest electrical apparatus. In nearly all cases each tool will have a motor directly attached to it. Belting and shafting will thus be reduced to a minimum. It is the desire of the company to make this a model plant and the shop will, no doubt, contain many new and interesting features.

The "Paragon" Ball-Bearing Speed Indicator.

THE improved and perfected speed indicator illustrated below is the result of a good deal of experimenting and expenditure of time and money. It has been placed on the market by Lintner & Sporborg, Gloversville, N. Y., and possesses the following admirable features: It has a pistol-form grasp, by which the contact is made, and a trigger-form lever for starting the connecting mechanism, just the form of mechanical appliance to secure accuracy at starting and stopping. Made as it is with ball bearings to take up the end thrust friction, the latter disappears as a defect, and does not interfere with and make an incorrect record and having reversing worm-gears to actuate the dial, the indicator turns in the same direction with opposite revolutions of the shaft, so that its recordings do not have to be



"PARAGON" BALL-BEARING SPEED INDICATOR.

read backwards, when revolutions opposite that shown in the dial are recorded. To the manufacturer using power, the "Paragon Speed Indicator" will prove of great value, for by it the fact can readily be determined as between the revolutions of a main driving shaft where the speed is multiplied therefrom with belt connection to other shafts, and whether the latter are doing their work without intermediate loss and waste of power, and in many cases by being able to determine these and other facts with accuracy, it will in a year save a hundred times its cost.

A Hard Rubber Combination.

A combination for the purpose of regulating and protecting prices has been formed by the three largest hard rubber manufacturers in the country, which are to be consolidated into one concern. They are the India Rubber Comb Company, whose works are located at College Point, N. Y.; the Butler Hard Rubber Company, of Butler, N. J., and the Goodrich Company, of Akron, O. The concern will be incorporated under the laws of New York, and with a capital stock of $2,500,000. Of late years prices have been badly cut, and it is hoped to keep them at a normal level by this consolidation.

New Walker Installations.

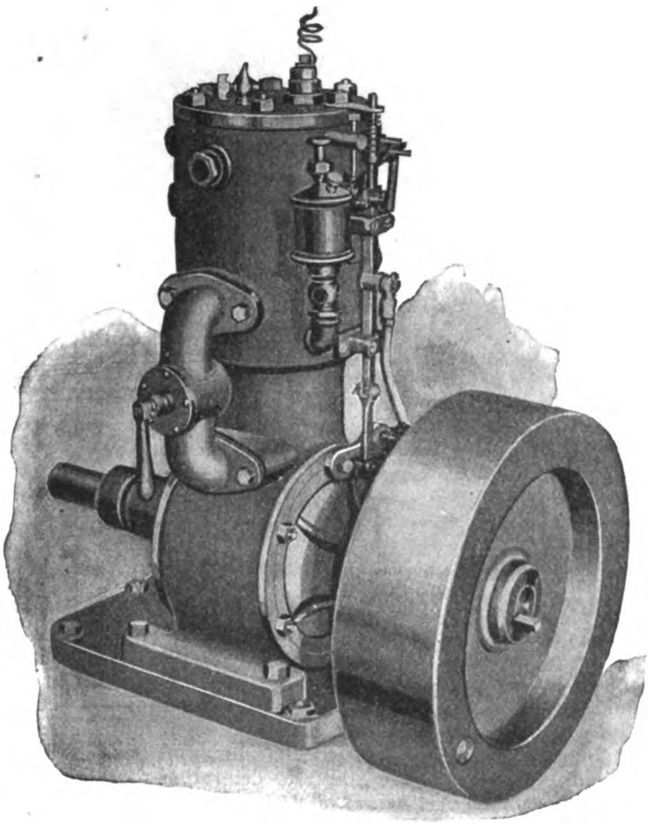
The Walker Company will shortly install two 6-pole 100 kilowatt lighting generators in the Metropolitan Museum of Art in New York. The Presbyterian Hospital has also placed an order with the company for a 100 kilowatt generator and switchboard. A Walker alternator, 3-phase 60 cycle for lighting and power has been purchased by C. Burkhart, of Hudson, Wis., while the Los Angeles Traction Company, of Los Angeles, Cal., has ordered a 500 kilowatt railway generator of the belted type and a generator panel for the switchboard.

Among the electric railway equipments recently ordered may be mentioned 10 double 3 S equipments with type S controllers sold to the Erie Construction Company for the Buffalo Traction Company; 3 double 40 horse-power equipments with S con-

trollers to Isaac A. Walker & Son for the Quakertown (Pa.) Traction Company, and two double 3 S equipments for storage battery motor cars to S. M. Fisher for the Patton Motor Company.

The Mianus Gas and Gasoline Engines.

THE steadily increasing popularity of gas and gasoline power for driving machinery and for propelling boats and vehicles, has led to the perfection of a gas and gasoline engine by the Mianus Electric Company, Mianus, Conn., which is peculiarly fitted to supply the demand, excelling in economy, safety and durability. The company are manufacturers of complete gas or gasoline engines of from one to six horse power, both stationary and marine, and can supply the castings, parts and working drawings for the one horse power and two and one-half horse power engines, for experimental purposes and for those who wish to construct their own engines. The accompanying illustration shows the two and a half horse power "Palmer" marine gasoline engine, built on the two cycle compression type, with an impulse at each revolution of the crank. The company also build them on the four cycle type having an impulse every other revolution. These engines are readily adapted to motor carriages and are also used for running printing presses and dynamos for electric lighting. They occupy but little space and consume a small quantity of gasoline or gas.



"PALMER" MARINE GASOLINE ENGINE.

Electric Motors For The Brooklyn Navy Yard.

The Bullock Electric Company has received orders from the Secretary of the Navy for twelve motors for use in the machine shops in the Brooklyn Navy Yard. The motors range from 5 to 40 h. p., are wound for 220 volts and are either to be direct-connected or belted, and several will be attached to the ceiling. The dustproof starting boxes for these motors were manufactured by the Iron Clad Rheostat Company.

Ball Engine Co.

On account of the great demand for their engines for electric light and power purposes, the works of the Ball Engine Company, Erie, Pa., builders of the Ball engine, have been operated night and day since Sept. 1.

Upton "Midget" Enclosed Arc Lamp.

THE "Midget" enclosed arc lamp, manufactured by the Standard Thermometer and Electric Company, Peabody, Mass., has given so highly satisfactory results that future installations by the company of arc lamps on 6.7 ampere circuits will doubtless be confined largely to the enclosed long burning type. Its advantages over the open arc lamp are many and valuable.

With the "Midget" lamp, shown in Figs. 1 and 2, a variation of from 4½ to 7 amperes does not affect its satisfactory operation; or, if desired, the arc machine can be run constantly at 6 amperes or less, affecting the candle power very slightly, and making a saving of course in fuel. Few types of open or enclosed arc lamps will stand a variation of even one ampere without seriously interfering with their steady operation. The "Midget" lamp burns steadily, without any flicker or shadow, diffusing the light more evenly and at a greater distance from the lamp than the open arc. In the latter, the light is most brilliant directly beneath the lamp, and the diffusion not nearly so efficient.

Actual tests have proven to the satisfaction of users, that the enclosed arc series lamp taking from 65 to 75 volts, (averaging 70) at the arc at 6 7-10 amperes, gives fully as desirable a light as the open arc lamp taking 45 to 50 volts on 9 8-10 ampere circuits. The saving in carbons resulting from trimming the lamp only once in 125 hours instead of every day is considerable. On large installations the saving of labor is also an important item. The arc of the lamp being enclosed is not affected by snow-storms or inclement weather, as in the case of open arc lamps. The cut shown illustrates the indoor type, as well as the mechanism. The lamp is designed to fit standard hanger boards and hoods for street service.

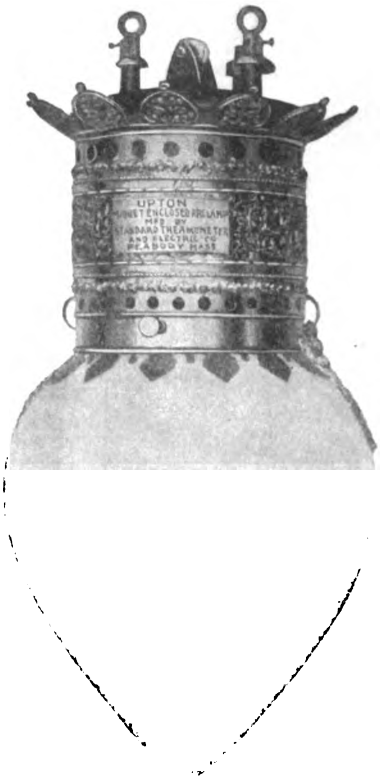


FIG. 1.—MIDGET ENCLOSED ARC LAMP.—EXTERIOR VIEW.

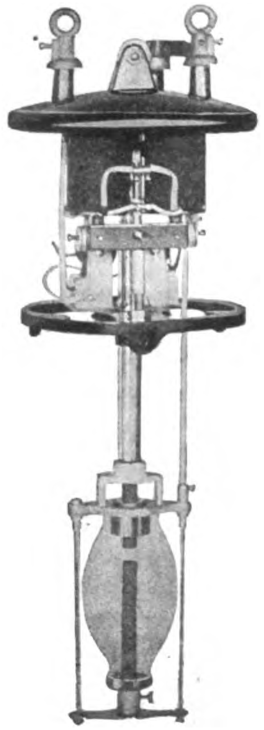

FIG. 2.—MIDGET ENCLOSED ARC LAMP.—INTERIOR MECHANISM.

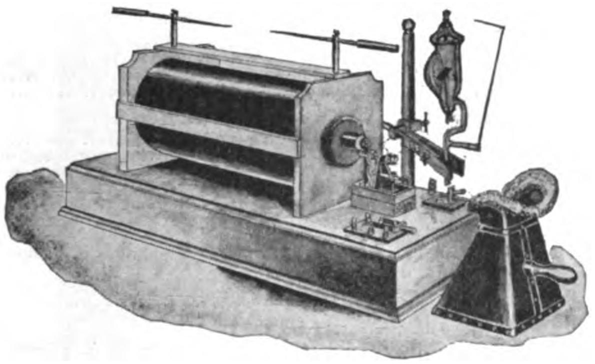
An automatic cut-out is provided with each lamp. It is constructed with an especial view to economical operation. All the energy expended in the lamp is consumed at the arc and not taken up by heavy series coils. It is not a differential lamp, but a plain shunt lamp with a series winding for starting, thus enabling it to operate without injury on circuits varying from 4½ to 7 amperes without readjustment. The candle power of the lamp can also be raised or lowered irrespective of the amperes by a simple method of lengthening or shortening the arc. If for any reason the voltage at the arc goes above 80, the cut-out operates, shunting the current through the series coil and

restarting the lamp. If the carbons are burned out or stuck, the lamp remains out of circuit at a loss of three volts necessary to hold the cut-out. Station managers will find that in this lamp the constantly recurring troubles on account of burnt-out magnets, worn-out clutches, and jammed carbon rods have been overcome. The lamp contains no springs nor dash pots, the absence of which is of especial interest to station managers who have experienced these difficulties. The only moving part of the "Midget" lamp is the magnet core with its clutch. The mechanism is easy of access, and method of trimming the same as in the other "Midget" lamps described in a previous issue.

Williams' New X-Ray Coils.

THE extensive introduction of commercial X-ray apparatus has had the effect of developing and improving it so as to meet all practical conditions. Induction coils, tubes, fluoroscopes, condensers, vibrators and sensitive plates have all received the closest attention of experimenters and this has resulted in placing very efficient apparatus in the market. The coil illustrated below is the result of long study and experimentation by Mr. E. Q. Williams, 316 and 318 East Water street, Syracuse, N. Y. The coils are made in all sizes, giving sparks of from 3 to 15 inches. This length is rated for a continuous spark and not for an exceptionally long flash which may be obtained occasionally. The coils are wound with No. 34 wire,



WILLIAMS' X-RAY COIL.

and with ¾ pound of wire, a one inch spark is obtained which is highly calorific. The coils are insulated by a new and original method, designed by Dr. Eugene Haanel, of the Syracuse University, which insures perfect insulation between the primary and secondary coils and between the sections of the coils themselves. The vibrator is of the latest type and breaks the circuit when the hammer is in full swing, giving a long make and a very short break. A weight is attached to the hammer which can be adjusted so as to change the rate of vibration. The condenser is made in sections and is adjusted by turning the handle shown at the right, which cuts the various sections in and out. The materials used in these coils are all selected to give the highest efficiency and long life. The coils are made for either battery or 110 volt d. c. circuits, with or without the vibrator attached.

An Improved Sand Box.

THE Ham sand box, illustrated herewith and sold by the Electric Appliance Company, of Chicago, is based upon the theory that any box provided with a valve at its bottom is impracticable; and if the valve be made tight enough to prevent the sand from sifting through, it will require great force to operate it, while if the valve be loose enough to work easily, it will allow the sand to sift around it.

In the No. 3 Ham sand box illustrated, all parts are made of bronze metal. It has an opening in the box, under which is a curved shelf. The ends of the shelf extend beyond and above the opening in the box, so the sand cannot escape by gravity. A paddle is reciprocated above the shelf, and the movement of the paddle forces the sand in each direction alternately over the ends of the shelf to the feed spout which leads to the car track. Above the paddle are two fingers which stir the sand. The connecting rod passes forward to the car platform, and is operated by a pin and ball crank lever, or by a hand lever. The working parts are extremely simple and the motions direct. The strokes of the foot or hand may follow each other so rapidly as to practically secure a continuous, but small, stream of sand, a decided advantage in hill climbing. It can be easily seen that waste is impossible in this box, as the sand flows only when the lever is in motion, and the quantity of sand is regulated. Small stones or other small substances will not interfere with the operation of this box, but will pass freely through it. In fact,

HAM SAND BOX COMPLETE AND IN SECTION.

the company recommends coarse in preference to fine sand, even if it contains gravel stones as large as peas, as it is less likely to pack in the box. The manufacturers state that they have unsolicited testimonials favorable to the box, received from prominent railroad men.

CATALOGUES.

Switch Catalogue of Zimdars and Hunt.

A very handsome and useful catalogue has just been issued by Zimdars and Hunt, 127 Fifth avenue, New York, manufacturers of knife switches, switchboard fittings and electric light and power specialties. The apparatus manufactured by this company is of the very best quality, all current carrying parts being made of pure drawn Lake Superior copper of the highest conductivity. Great care has been bestowed on the mechanical points, both in design and construction. Symmetry and beauty of design have also not been neglected and the trimmings are of neat and effective patterns. The catalogue contains illustrations and price lists of all types and sizes of switches, as well as switchboard connections and instruments. The cover of this very artistic catalogue is an imitation of the marbleized slate bases employed by the company.

Lakon Transformers.

The Western Electric Company has recently issued Bulletin No. 25 descriptive of the Lakon transformer. This bulletin illustrates the iron stampings from which the transformers are built up; several different sizes of transformers, and the methods of connecting them to obtain either 50 or 110 volts; also hanging device and special fuse box.

The Lakon transformers are made for long distance transmission for the ordinary 1,000 and 2,000-volt primary and 110 and 50-volt secondary for 3-wire system and for arc light transmission. They are all insulated and can be run either as dry transformers or oil insulated transformers.

The Lakon transformers have no joints on the top or sides the only joint being on the bottom, thus making the case thoroughly weatherproof without the use of cement or other material to fill up the cracks. The larger sizes are placed in either an open case for inside use or in weatherproof case for outside use.

The Harrington System Labor-Saving Appliances.

Edwin Harrington, Son & Company, of Philadelphia, Pa., have issued a very complete catalogue illustrating their well known hoists, tramways, traveling cranes, tools, and special machinery and labor-saving devices. The hoists manufactured by this company were introduced twenty years ago, and have been adopted by the United States Government. It has independent working chains, the load being carried on two distinct chains, each link having a breaking strain greater than the rated capacity of the hoist; this reduces the possibility of accident. Some of the apparatus illustrated in the catalogue are the double hook screw hoist, the twenty thousand pound hoist, the rope winch, combined hoist and electric motor, single track railway, combined hoist and traveler, turn tables, wall and arm cranes, and illustrations showing the use of overhead tramways in storerooms and factories.

NEW YORK NOTES.

DR. DURAND WOODMAN, analyst and chemical expert, has just issued a circular informing his friends and clients that, to meet the increasing demands of his professional work, he has taken additional laboratory and office room, and telephone service, the latter especially being a convenience for out-of-town clients. These additions will facilitate not only the work of the department devoted to commercial analysis, but also the experimental and expert work for inventors, patentees, their attorneys, and solicitors, as well as the technical investigations for manufacturers and others. As in the past, everything pertaining to inventions or manufacturing processes entrusted to Dr. Woodman will be held strictly confidential. Dr. Woodman's offices are at 80 Beaver street; telephone, 1413 Broad, New York.

MR. GEO. T. HANCHETT has opened an office at 123 Liberty street, where he will continue his practice in electrical engineering, and will make a specialty also of electrical and mechanical machine design. He has complete facilities for making drawings and constructing machinery and models under close supervision.

MR. S. B. CONDIT, of the firm of L. A. Chase & Company, Boston, recently visited New York and has made arrangements with Mr. Nisbet, president of the Electrical Appliance Company, 39 to 41 Cortlandt street, to handle their gravity motor controllers for the entire East. Under the new conditions we are informed the Electrical Appliance Company will be obliged to greatly increase the present output of their new factory, located at Hoboken, N. J.

THE DIAMOND STATE TUBE COMPANY, Elsmere, Del., have recently put on the market a waterproof, fireproof tubing for electrical installation which is meeting with ready sale. It is claimed to be superior to anything heretofore used and cheaper. Samples and prices can be had on application.

ADVERTISERS' HINTS

THE AMERICAN RHEOSTAT COMPANY, Milwaukee, Wis., say their rheostats are doing their share to make Milwaukee famous for other things besides beer. The rheostats are good—so is the beer.

THE WORTHINGTON COMPANY, New York, wish it remembered that they make condensing apparatus for all known conditions of service.

WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburgh, Pa., call attention to the transmission of Niagara Falls and the St. Lawrence in which connection they refer to the 5,000 h. p. units installed by them in both plants.

THE C & C ELECTRIC COMPANY, 143 Liberty street, New York, advertise power generators for railway or stationary motor service and illustrate one of their multipolar generators direct connected to an Imperial engine.

THE BOILER EXPURGATOR COMPANY, 115 Dearborn street, Chicago, Ill., cite an instance where the use of their boiler compound prevented the sale of a new battery of boilers as the old one improved so much after its use that the new one was not required.

THE WALKER COMPANY are advertising enclosed arc lamps for incandescent circuits.

THE DELAWARE HARD FIBRE COMPANY, Wilmington, Del., say their name is a guarantee of high quality, reasonable prices, prompt service and polite attention.

THE COLUMBIA INCANDESCENT LAMP COMPANY, St. Louis, Mo., will make special prices on annual contracts where the requirements equal or exceed 1,000 lamps.

BLAKE & WILLIAMS, steam and electrical engineers, 362-4 West Broadway, New York, make a specialty of the manufacture and design of high grade switch and panel boards.

WESTERN ELECTRIC COMPANY, Chicago and New York, have a word to say about "Simplex" friction tape. A sample roll may be obtained free.

HART & HEGEMAN MANUFACTURING COMPANY, Hartford, Conn., claim their switches to be the best and the cheapest.

The Electrical Engineer.

Vol. XXV. MARCH 17, 1898. No. 515.

ELECTRIC LIGHTING

The Dolgeville, N. Y., Electric Light and Power Plant.

THE greatest day in the history of Dolgeville, N. Y., was Saturday, January 15, 1898, when Hon. Timothy L. Woodruff, Lieutenant Governor of New York, turned the wheel which put into operation the power for the generation of electricity to transmit it far and near for lighting, heating and commercial and industrial aggrandizement.

Dolgeville, called "The Beautiful Little City at the Foot of the Adirondacks," is situated nine miles north of Little Falls, Herkimer County, N. Y., and about twenty miles from the city of Utica. This little city, bristling with enterprise and the spirit of industrial progress has now harnessed the rapid waters of the Auskerada, the erstwhile East Canada River, in order to run the looms and spindles in its mills and later perhaps the street car lines at Utica.

The rapid development of the city of Dolgeville is due largely to the efforts of Mr. Alfred Dolge, who controls a steam road between Dolgeville and Little Falls, owns felt factories and has a large interest in all the other various industries of Dolgeville. The population has increased from 200 in 1873 to 2,500 in 1897, and the property in valuation from $30,000 to $2,000,000. The population consists chiefly of Germans who are engaged in the manufacture of felt, piano sounding boards, and felt shoes.

The establishment of an electric plant for lighting and general power purposes greatly increases the efficiency of these various industries, and eliminates the smoke and other disagreeable features common to most manufacturing cities. This was recognized early in the history of Dolgeville, for in October, 1879, Mr. Alfred Dolge, ever and always in the front rank in the march of progress and improvement, at the very inception of incandescent lighting purchased and installed in his factory a 400 light generator, one of the first machines made in the United States, the number two of Thomas A. Edison, at present doing its work in the old power room of the Dolgeville Electric Light and Power Company, with an output of current for 800 lights, double its rated capacity.

As the manufacturing plant of Mr. Dolge increased, other generators were added and the citizens of the village were supplied with a cheap and efficient light service, thus early marked as a progressive community. In the year 1891, the Dolgeville Electric Light and Power Company was incorporated with a capital stock of $25,000, purchasing the plant of Mr. Dolge, and supplementing the light service with a service of power to all the manufacturing establishments of Dolgeville.

FIG. 1.—THE HIGH FALLS DAM WITH A PORTION OF THE FALLS IN THE FORGROUND. THIS PICTURE SHOWS A DEPTH OF 5 FEET OF WATER AT THE OVERFLOW.

Notwithstanding the low rate at which light and power has been dispensed here, a condition due to the small cost of initial power, the water, the company has been a commercial success. The net earnings on the capital stock of the company since its organization have been as follows:

	Per cent.
For the year 1892	10
For the year 1893	15
For the year 1894	22
For the year 1895	18
For the year 1896	22
For the year 1897	21

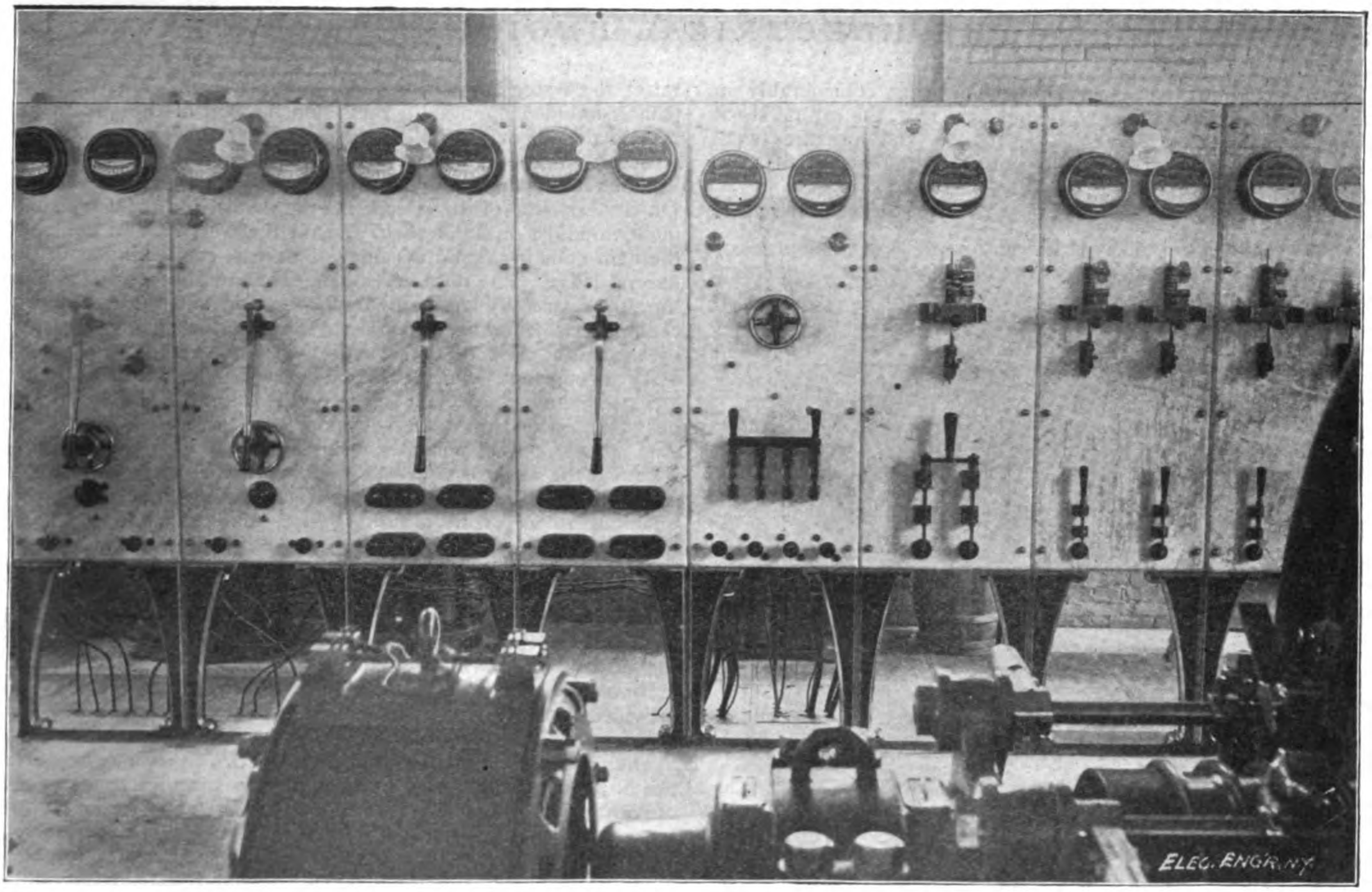

FIG. 5.—MAIN SWITCHBOARD, DOLGEVILLE ELECTRIC LIGHT AND POWER STATION.

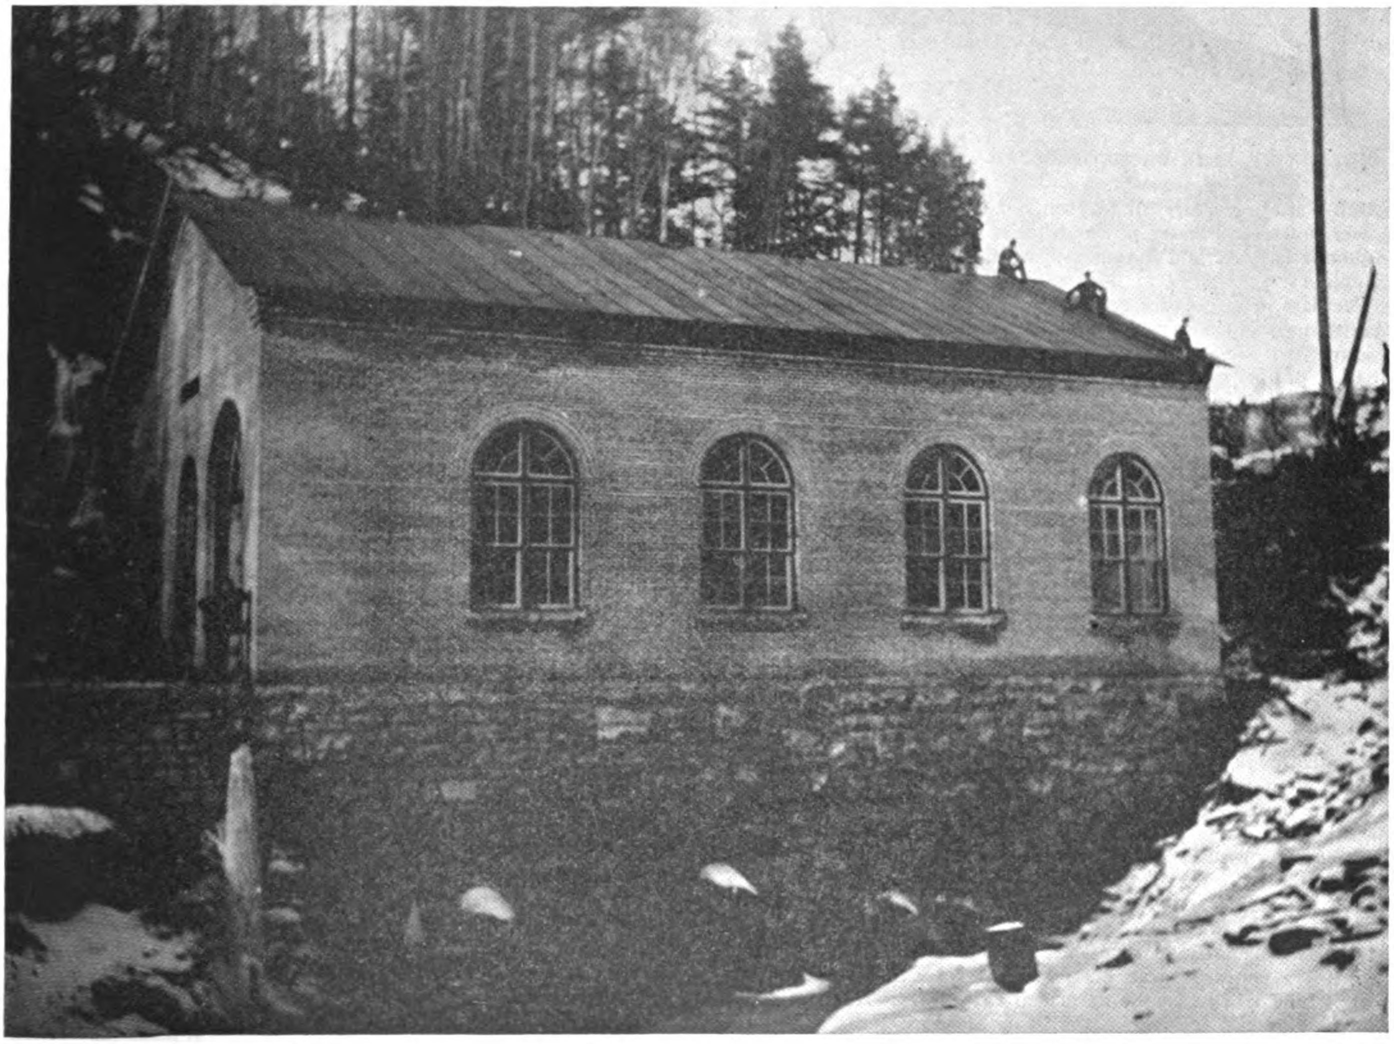

FIG. 2— POWER HOUSE OF THE PLANT OF THE DOLGEVILLE ELECTRIC LIGHT AND POWER CO. AT HIGH FALLS.

The demand for power in Dolgeville being considerably in excess of the ability to supply, in January, 1897, the capital stock of the company was increased to $100,000, and measures were taken to develop the High Falls power to the extent of 1,200 h. p. minimum.

Contract was made in May, 1897, with Stilwell-Bierce &

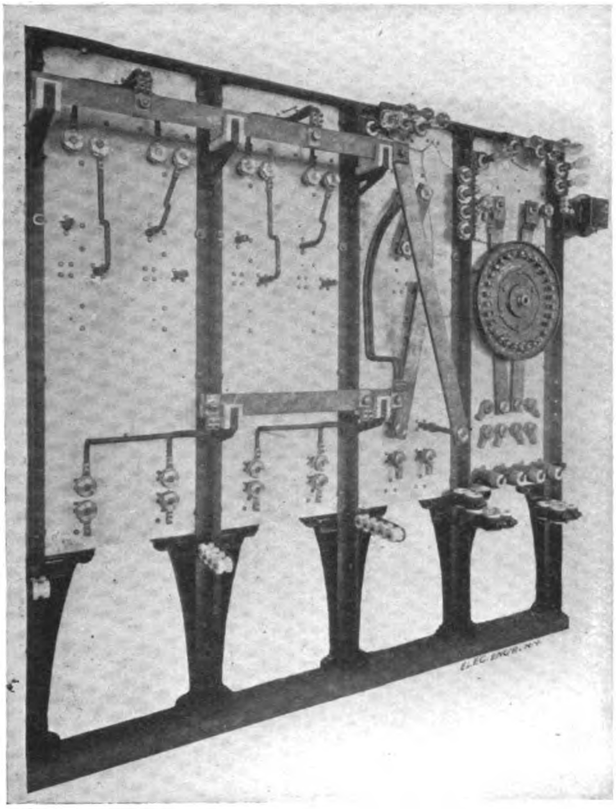

FIG. 6.—ONE END, BACK OF DOLGEVILLE SWITCHBOARD.

Smith-Vaile Company, of Dayton, O., to erect the dam, feeder, power house and water power wheels, etc., and with the Westinghouse Electric and Manufacturing Company for the electrical machinery.

The dam, gates, feeder and water supply, are constructed for a maximum of 3,500 h. p. The water wheels for present minimum use are two Victor wheels of 750 h. p. each, and a small wheel of 50 h. p. operating under a head of 72 feet. The water wheels, controlled by electric governors, are direct connected with two 600 h. p. each Westinghouse two-phase alternating current dynamos, 7,200 alternations 300 r. p. m. generating at 2,400 volts.

Power is transmitted to Little Falls upon three wires at a potential of 10,000 volts, and there reduced to a voltage of 2,200, for supply to motors by converters at any voltage desired.

After giving this brief history of this very interesting power development let us return to the source of power, the High Falls of the Auskerada River. This river takes its rise in the western section of the Adirondacks and is supplied in its course from small lakes, probably numbering nearly a thousand.

The development of a water power of the magnitude of this undertaking called for more careful thought and thorough study than would at first be apparent to the casual observer. Early in 1894 the Dolgeville Electric Light and Power Company, recognizing the high class talent employed by the Stilwell-Bierce & Smith-Vaile Company, arranged to have their Mr. A. C. Rice, chief engineer and general superintendent, make an examination of the proposed development, and to his examination, recommendations, plans and specifications, which have been faithfully followed, the splendid results now in daily evidence, are due.

Active operations were begun in May, 1897, and the work has been constantly prosecuted since that time, under the direction of the engineers of the Stilwell-Bierce & Smith-Vaile Company. The work may be described as follows: At a point approximately 100 feet above the brow of High Falls a masonry dam has been constructed, shown in Fig. 1, the crest of which raises the water 20 feet above its natural level. This masonry dam is founded upon solid rock, and the bed of the stream has been grooved, or dovetailed, in order that the masonry superstructure might not only rest solidly upon the foundations, but that the dam should be absolutely watertight at the base. On the east side of the stream the dam ends in a masonry abutment, founded on solid rock, and on the west side of the river the dam ends in a solid masonry abutment, connecting with the natural ledge. The masonry in the dam and abutment is a blue limestone carefully laid in hydraulic cement, and the recent successful tests from the unexpected floods give strong evidence of the high class of construction that was employed in the work throughout. Out of the abutment on the west side issues a waste gate of sufficient capacity to drain the pond for any necessities which may later develop. To the west of the waste gate a 10-foot steel penstock originates, and it is through this tube that the water is conveyed to the power house, a distance of approximately 500 feet. This penstock is supported at intervals of about 16 feet with masonry piers, founded upon the solid rock bed of the stream.

The power house, shown in Fig. 2, at which point the water is received, is situated in a canyon between two high cliffs and is founded upon solid rock and built substantially of stone and brick, all laid in cement mortar. It is ultimately expected that the power house will be extended beyond its present size, to accommodate the installation of 3,000 h. p. The power house is provided with steel roof and concrete floors, making the building practically fireproof.

The present installation consists of two Victor wheels of 750 h. p. each, which may be seen in Fig. 3, and a small wheel of 50 h. p. operating under a head of 72 feet. The water wheels are controlled by electric governors and are direct connected to the generators without flexible couplings. Each of the turbines is provided with an independent water gate, controlling the admission of the water to the wheel, so that in the event of any accident to either wheel the troubled apparatus can be examined without shutting down the plant.

The electrical equipment was supplied and installed by the

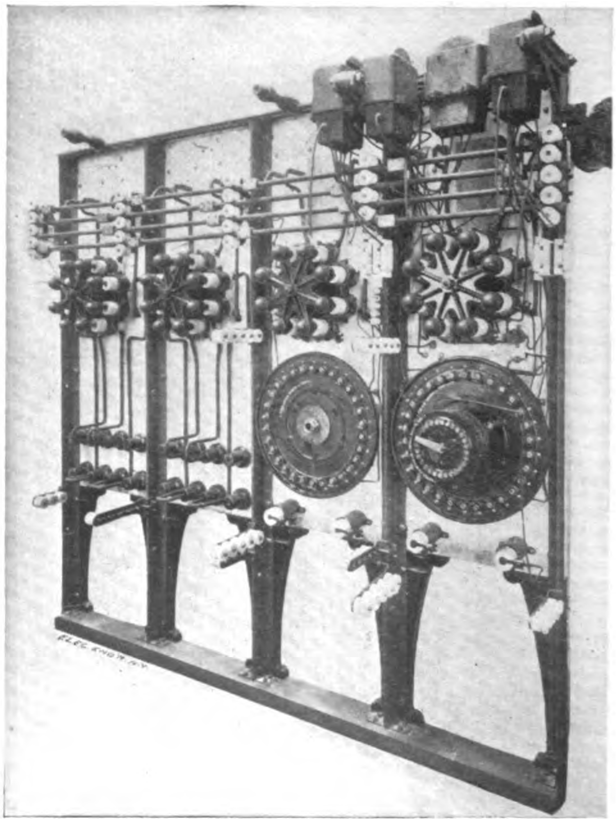

FIG. 7.—ONE END, BACK OF DOLGEVILLE SWITCHBOARD.

Westinghouse Electric and Manufacturing Company, and consists of the following apparatus:

Two 450 k. w. 7,200 alternations, 2,400 volt, 300 r. p. m. two-phase generators, direct connected to the water wheels, shown

in Figs. 3 and 4. One 15 k. w. 100 volt, multipolar exciter, direct connected to the smaller water wheel spoken of above. Two 250 k. w. 10,000 volt raising and two 250 k. w. 10,000 volt lowering transformers. One 250 k. w. revolving rotary transformer, 7,200 alternations, having a maximum potential of 600 volts. Two 150 k. w. lowering transformers and an eight panel switchboard for the generators, feeders and rotary, a front view of which is shown in Fig. 5. The back connections of the right hand direct current portion are shown in Fig. 6, and those of the left or alternating current portion in Fig. 7. In the latter figure will be seen the transformers and also the backs of the new Westinghouse high potential, quick break, plunger type switches, shown in detail in Figs. 8 and 9. These switches were designed and built on the principle that (1) an arc is maintained with difficulty when the circuit is quickly broken, (2) an arc tends to expand, it cannot therefore be readily maintained in a confined space, (3) an arc cannot withstand a strong transverse draft of air. The switches break the circuit quickly and in the case of the heavier currents, at two places in series in each side of the circuit, thus dividing by two the pressure at the breaking points. The break is made in a small enclosed air chamber, thereby limiting the expansion of the arc, and also by means of such expansion creating a strong lateral draft of air through a vent provided for that purpose and thus supplying the third and remaining requisite for a ready suppression of the tendency to arc. Similar switches have been used in the Niagara Power Company's plant in Niagara Falls, and it is claimed that with them it is perfectly practicable to break the lagging current of a 2,200 volt two-phase 5,000 h. p. generator fully loaded and without any sparking or burning of contacts whatever.

The Westinghouse generators are of the inwardly projecting field type, the armature being the revolving element, and are operated in multiple. The machines are excited by one 15 k. w. 100 volt multipolar generator, which is ample for both alternators.

The voltage of the rotary can be raised or lowered from 500 to 600 volts without shutting down the machine. Mechanically the rotaries are of the same general design as the generators, having horizontally split fields, etc. Electrically they consist of a Westinghouse alternating current motor and a Westinghouse direct current generator. A small starting motor is mounted on the end of the shaft.

The two-phase generators, which require four cables for transmission, by conversion into three-phase in the step-up transformers three cables only are required to form the line. This method, known as the Scott two-phase-three-phase system, saves 25 per cent. in copper and the same amount in the number of insulators needed.

The power is transmitted to Little Falls at a potential of 10,000 volts. It is there reduced by step-down transformers to 2,200 volts, and is then distributed to various other reducing transformers conveniently located for power purposes. The power is used for operating two-phase motors in a number of knitting mills and machine shops in Little Falls, and for lighting and operating direct current motors at Dolgeville. It is the intention of the company to equip all new factories with induction motors, and to gradually replace the direct current motors with motors of the induction type. It is further proposed to operate the steam road between Little Falls and Dolgeville by electricity.

In conclusion we venture to say that this is the beginning of an improvement of this locality for power, which is destined to be far reaching in its results to the manufacturing interests of the Mohawk Valley. Within five miles above and below the village is a total fall of 412 feet which can be utilized in seven plants, which when grouped and supplied with electrical machinery will furnish a steady and constant 20,000 h. p.

We are indebted to the "Dolgeville Herald" and the Westinghouse Electric and Manufacturing Company for the above data and illustrative material.

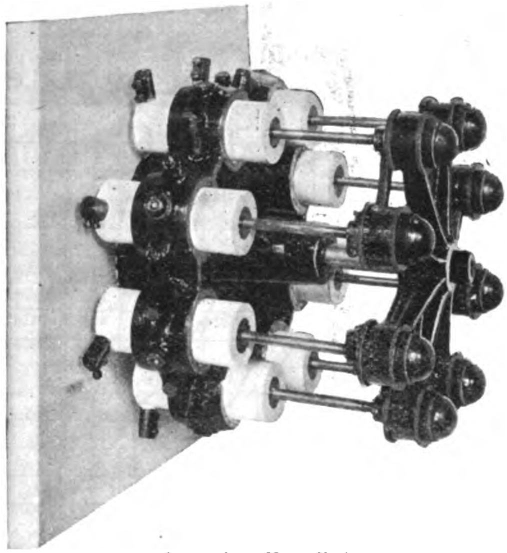

FIG. 9.—BACK VIEW.

FOUR-POLE DOUBLE BREAK SWITCH FOR TWO-PHASE CIRCUITS.

Experiments in Room Illumination.

BY I. C. THOMPSON.

WHEN the query arises as to how well a room is lighted, the answer usually is either brilliantly, very well or poorly, the estimation of each of these gradations being left to the individual judgment alone. It is the same with heating and ventilation. The writer never has seen a specification for any building specifying the foot-candles of illumination, degrees of temperature or the hourly percentage change of air. True, these factors may vary greatly, but not so when standard conditions are also given. There is great room for development in this direction, having for its main object definiteness, so that each room will have the above factors closely specified in definite units just as the steel or cement entering into construction is specified.

It was required to determine whether a small room, Fig. 1, was sufficiently lighted by means of a central, pendant, 16 c. p. incandescent lamp, and the force of the above remarks became at once apparent. One lamp was used in this room and but one was used in rooms twice the size, the former, of course, being the more brilliantly lighted, but not necessarily sufficiently, the latter being the point under determination. According to Siemens, a floor space of five square feet per candle or 80 square feet for the 16 c. p. lamp is sufficient; this room has an area of

$9 \times 14 = 126$ square feet, and would therefore require a 25 candle illumination, such as is given by a five-foot gas burner using New York City gas. Uppenborn gives five to seven square feet, the latter allowing a 112 square foot room. Kermanner and Prausnitz state that 0.73 to 0.83 foot-candles (horizontal) illumination is sufficient for all ordinary purposes, and that 0.90 to 0.95 foot-candles are sufficient for readers and

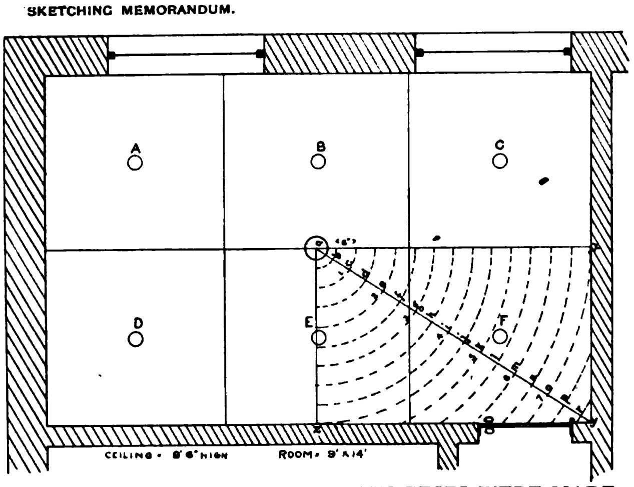

FIG. 1.—PLAN OF ROOM IN WHICH TESTS WERE MADE.

writers, while Cohn recommends about one foot-candle. The latter is seldom attained in practice by means of general illumination, separate lamps being supplied each individual, as in libraries, or private tables and desks, and here the illumination may become twice this amount.

Following the method of blocking out an area to arrive at the average illumination and making the tests at the centre of each square, it was found that the results obtained were undoubtedly too low. These, and all subsequent tests were made with the top of the photometer box horizontal and 30 inches above the floor, the lamps being four feet above this in all cases but two, which are so designated. These were the results obtained with a 16 c. p. lamp:

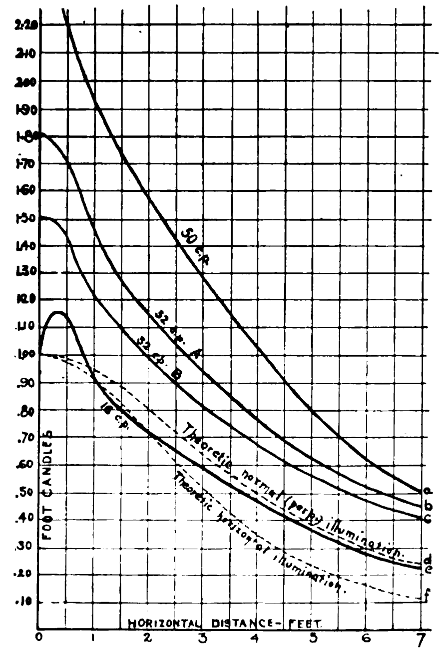

FIG. 3.—CLEAR GLASS BULB.—POSITION I., FIG. 2.

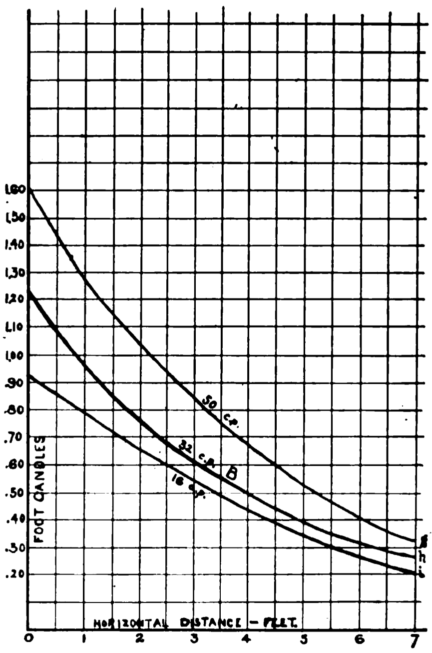

FIG. 4.—CLEAR GLASS BULB.—POSITION II., FIG. 2.

Location of points of observation.	A	B	C	D	E	F	Mean.
Naked bulb	.23	.75	.20	.20	.70	.20	.38
Fluted shade directed downward	.32	1.10	.23	.25	1.10	.25	.54
Fluted shade inverted	.19	.47	.20	.19	.43	.20	.28

As this method was not satisfactory it was decided to construct the theoretic curve giving the illumination at successive horizontal distances, considering first that the effect varied inversely as the square of the distance from a point of light for normal illumination, and directly with the sine of the angle the light ray makes with the horizontal for horizontal illumination. These two curves are shown as d and f, Fig. 3. The effect of inclining surface to the light ray is therefore very marked.

Tests were then made along the lines ax, ay and az, Fig. 1, and the illumination for equal distances found not to vary much

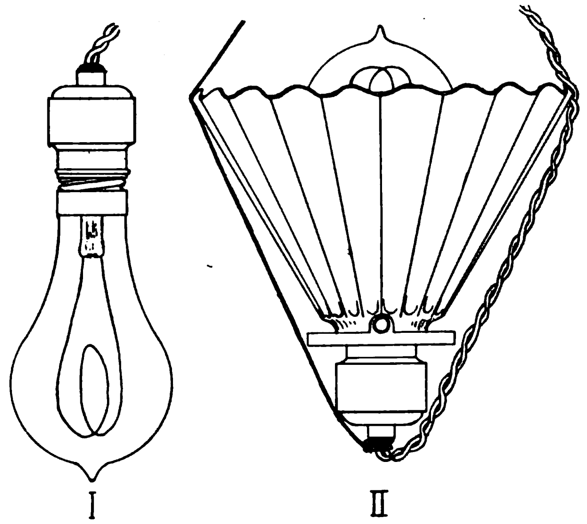

FIG. 2.—POSITION OF LAMP AND SHADE.

except to increase slightly near x and z, on account of wall reflection. All subsequent tests were therefore made along ay. From the results obtained, curves a, b, c and e, Fig. 3, were constructed. Curve a, for example, begins at 2.50 and should theoretically drop to $0.12 \times 25 = .30$, whereas it drops to .50; curve b drops to .45 instead of .22, and curve c to .41 instead of .18. This shows a considerable amount of ceiling reflection. In fact, when the direct rays are screened off in making curve i, Fig. 4, 0.18 came from the ceiling at three feet and 0.16 at six feet distance, while in taking curve m, Fig. 5, the shade being directed downward, but 0.03 foot-candles was obtained from the ceiling alone. The candle-powers of the lamps were those marked upon them by the makers; a crude test showed them to be approximately correctly marked; this point is immaterial, as it was distribution rather than intensity that the tests were made for. Curve c here had an average of 57.8 foot-candles. As the candle power becomes higher the curve becomes more regular, indicating greater diffusion, possibly.

It was suggested by Kermanner and Prausnitz that conical shades be inverted, transmitting part of the light and reflecting the remainder into the ceiling. It was accordingly decided to see what effect this would have upon the curves, as the shade in Fig. 2, position II., was tested with the results seen in the curves of Fig. 4. The illumination was reduced thereby about 33 per cent. for the 50 c. p. lamp; 25 per cent. for the 32 c. p. lamp, and 10 per cent. for the 16 c. p. lamp. The effect, however, was admirable and eminently adapted for room illumination, although the average for 16 c. p. was 0.52 foot-candles; the light was soft and noticeably easy on the eyes, more so than ground glass. Opal shades are, however, made too thick for this purpose, and cut off more light than is necessary. The less difference there is in the brightness of adjacent parts, the easier the light is upon the eyes; this, of course, renders it necessary to screen the light source, and at the same time adjust the light coming through the shade and from the reflecting surfaces, such as a ceiling, so that the brightness shall be as uniform as possible—a solid mass of light. By properly shaped opal reflector-shades the curves in Fig. 4 could be still more flattened, especially if the ceiling is white.

Still other tests, plotted in the curves of Fig. 5, were made which show how great an effect the kind and position of a shade

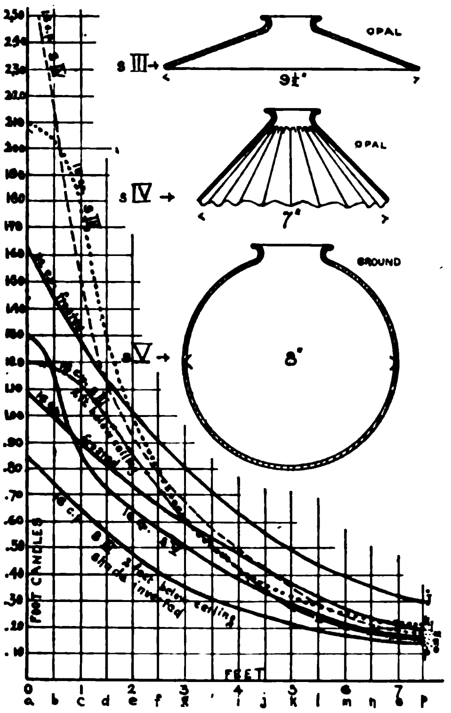

FIG. 5.—CURVES SHOWING THE ILLUMINATION WITH VARIOUS SHADES.

has upon a light. Curve m gives greater illumination than curve i, but it is of an entirely different quality; it is too harsh. The principal advantage of the ground glass shade V., curve n, is its beauty. The light from ground glass does not seem so pleasant as that from opal shades, but the effect of a large sphere of light in a room is decidedly more artistic than a clear glass bulb. For the general illumination of Columbia University Library these spheres, enclosing 16 c. p. lamps, are used both suspended and supported by columns, while a seven-foot sphere suspended in the dome is rendered luminous by the projected rays of eight powerful arc lamps.

Shade s III., Fig. 5, is a good downward reflector, but a poor diffuser, being not nearly so good as the inverted s IV. Shade s V. was suspended from a pulley so that it could be raised to the ceiling out of the line of sight, where it gives .75 foot-candles, or lowered within two feet of the table, giving in the latter case an illumination of 2.6 foot-candles upon the table; thus, when reading or writing are in order, the globe is lowered, and again raised to the ceiling when an intense light is not required. These globes can be stained yellow, orange or rose by colored solutions washed upon their interiors; a rich cream color, however, being preferable. Numerous other combinations will at once suggest themselves.

It does not pay to put up with the discomforts and possible injury to eyes incident upon the use of naked lights of any kind. This is evident with the now popular Welsbach lamps, which are almost invariably inclosed by shades of some sort for interior illumination, and these shades add considerably to the ornamental character of a room. If electric companies would take equal pains to make the incandescent light pleasant and ornamental, the results would no doubt soon be manifest in increased earnings. The fact is, that in the past year, small and large stores have sprung up in every locality which handle Welsbach shades of highly ornamental design, whereas it was only after considerable trouble that a store could be found where the shades used in these tests could be obtained.

It is probable that the best shade for diffused lighting would be an inverted conical glass shade with straight sides, having an angular opening of about 90 degrees, ground on the outside so as to transmit more light than an opal shade, and reflect the remainder up against a light colored or preferably white or slightly tinted ceiling, and of such a size as to conceal the bulb itself. This would probably give the highest results per lamp in comparison with other diffusion methods.

It scarcely pays to use a 32 c. p. lamp or one of higher power. It would seem better to be able to raise and lower the bulb to obtain a desired brilliancy; certainly 2.6 foot-candles is enough for reading, and a mean general illumination of 0.5 foot-candles for other purposes, and both these can be had by raising and lowering a 16 c. p. lamp in a spherical ground glass shade. Ground glass bulbs give good illumination results, but are still quite intense when looked at. The diffusion surface is not large enough.

These tests are relative. There was considerable variation in results at various times, showing that the current varied; the candles differed in quality, and the lamps decreased in intensity. The comparative figures on the same curve, however, are accurate, and it is this point which was to be determined.

TELEPHONY AND TELEGRAPHY

Practical Features of Telephone Work.—I.

BY A. E. DOBBS.

PITFALLS IN STARTING.

THE rapid growth of independent telephone companies in the past two or three years has led to numerous and costly experiences on the part of some of their owners, many of whom having spent their lives in other pursuits, and having but vague and uncertain ideas on the subject of telephone construct.on and management, frequently acquire their knowledge at a price that would build a plant of twice the capacity of the ones they now possess. Many exchanges are equipped without regard to future, or even present needs, an increase of business necessitating a partial or entire rebuilding of the plant, and rebuilding is costly.

As a general thing the building of a new exchange proceeds something after this fashion: A canvass of the town is made to secure the necessary number of subscribers, and sell stock. It is successful. When the capital has been secured, the question comes as to how the plant is to be built. Most of the men who furnish the capital know nothing of the business. They often send a committee off on a junket to visit one or two exchanges built by people as ignorant as themselves, and said committeemen come back with the idea that they know how an exchange should be built. An experienced concern would employ a competent engineer to make plans and estimates and superintend the construction of the work, but a new and inexperienced company with a calm confidence born of ignorance, in nine cases out of ten regard this as a useless expenditure, because there are any number of contractors willing to furnish them all the plans they want free of cost; and the idea is firmly rooted in their minds that the contractor will do the work much cheaper and better than they can do it themselves and in this they are partly right if present needs only are considered. Remember, however, the contractor must have his profits; he has to live. A number of contractors bidding against each other will offer to

put in a certain number of telephones for a certain price, an amount which will probably be less than an engineer's estimates, and lower than really good work at a reasonable profit demands. Now, the successful contractor may be a man who has followed railroad work, or cellar excavations, or electric railroad work, but even a telephone contractor with an ordinary conscience will not do any more work than the plans call for; especially if sharp competition has cut the price down to the last notch.

Well, the exchange starts out in business and if fairly well managed the lower rental charged increases the demand for telephones beyond all expectations, and the plant being totally inadequate to the demand upon it soon has to be practically rebuilt at a cost considerably higher than would have put in the entire plant in the first place. If not rebuilt, poles, lines and switchboard being overcrowded, poor service, constant interruptions and repairs, and in some cases bankruptcy, are the result. I know of two or three exchanges that have been almost entirely rebuilt three times in the last four years.

Nor can the original contractor be blamed for this state of affairs. It is not his place to tell owners what they should do, or what they should not do. Even if his advice was offered, he would probably be suspected of some ulterior motive, and his advice taken like dreams, by contraries. It might be, as sometimes happens, that he is himself a stockholder in which case he probably would do as well as he knew how, but it does not always follow that he knows how. Almost any contractor, however, prefers to get a reputation for first-class work, but if the owners cannot be made to understand what good work requires, he cannot be blamed for carrying out the plans or rather lack of plans, furnished him, and I even know of first-class construction men who have accepted plans under protest and put in work which they knew was inadequate. No real estate man would put up a building without consulting an architect, but a telephone plant which requires as much or more real skill for its construction and operation is often put in without plans or system.

Poor work in a telephone plant shows up worse than in almost any other kind of electrical construction; for where other circuits are numbered by a half a dozen, or even a score, of wires, telephone circuits are numbered by hundreds. There is not, I will venture to say, a power, or lighting pole line in the country carrying ten arms, and the only telegraph line I know of having anything like this capacity extends only a short distance from a Jersey City office. Yet in telephone work, ten or more arms on a pole is so common as to excite no comment whatever. Poles that will do for electric light and power or telegraph work, are of little use on such lines as these, and while it is true that arms and wires are lighter, yet the strain on the wires and poles is considerably greater in the aggregate.

Yet in contract work we often find poles with 4-inch tops carrying from 25 to 50 wires: and a badly buckled and disreputable looking line is the result.

In one plant of nearly 1,000 subscribers, the contractor put all his lightest poles on corners, perhaps under the impression that because two corner poles were close together, they did not need to be so heavy. Unanchored stubs were put down in a yielding clay soil to hold guys for corner and terminal poles carrying from one to two hundred wires. Junction poles were cross-armed in such a way, that the crossing wires became veritable crows' nests, making it almost impossible for a man to get to the top. Poles crossing other wires were not tall enough, and stringing wires along this line involved them in constant trouble with other companies.

Of course this plant has to be rebuilt in parts, and it was so badly mismanaged from the start, that many a contractor would be glad to build a better one at half its cost.

Nothing will drive away customers so quickly as a slouchy and bedraggled looking line, especially if the "old" company has been doing new work around the same town, to furnish a standard for comparison; for whatever may have been the faults of the old company in the past, its present work is done upon knowledge gained by 20 years' experience, and is of the most thorough and substantial character. People have the same prejudice against shabby looking work, that they have against a shabbily dressed man; and the only way to convince them that the "New company" has come to stay is to make the new work equal or superior to that of the older company.

I know of several exchanges that have almost doubled their subscription lists by rebuilding in the proper manner, and while rebuilding is expensive, because the work drags, for everything must be kept working, yet in many cases the added business has made it a profitable undertaking.

A man who engages to superintend the building of an exchange should be familiar with inside as well as outside work for often we will find exchanges equipped with good instruments, and poor outside work, and vice versa. Sometimes a contracting company makes a specialty of switchboards and will sublet the contracts for instruments and outside work. In many cases there is a disposition on the part of managers to look out for bargain counter instruments, though a brief experience is generally sufficient to convince them of this error. Others will try every make of instrument offered them, and get loaded up with all kinds, shapes and sizes, and so many different ways of wiring, that the hapless instrument man is driven to drink or worried into an early grave. The service carried on between bridged telephones and series telephones, high resistance and low resistance coils; bell magnets in series, shunted and cut-out; to say nothing of the different makes of transmitters and quantities of battery, becomes anything but uniform or desirable. But the men to be pitied are those who are loaded up with instruments purchased two or three years ago. It seems hard to have to throw away instruments that have only just begun to pay dividends, but if you are met by sharp opposition it will have to be done. Old instruments can often be worked off on small villages or private lines where they are looking for bargains and where the service is not exacting. Some managers desiring to get the best of everything will erect 40 foot poles where 25's would do just as well, buy heavy copper wire where No. 14 iron would answer every purpose, five cent insulators when those costing two cents would be amply sufficient, and in many other ways incur expense without regard to circumstances. That is simply a waste of money not justified by any prospective earnings; but to crown all, we sometimes see this material put up in a very inferior manner. If readers think this censorious or an overdrawn picture, a trip through the country will convince them that it is short of the actual facts. Of course in a discussion of this kind, names and places cannot be given, but two illustrations of working toll lines will suffice.

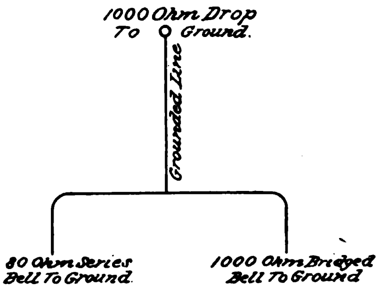

FIG. 1.

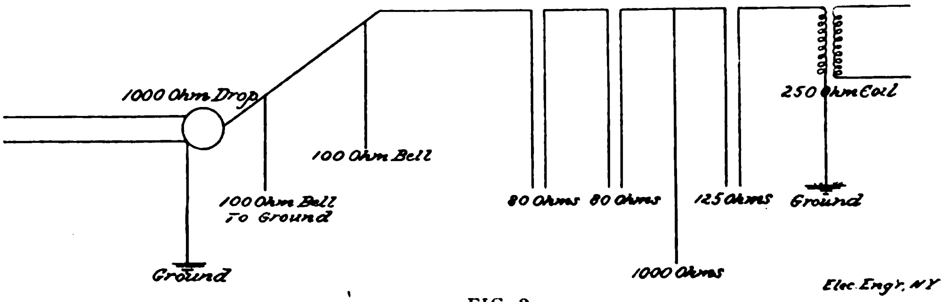

FIG. 2.

Fig. 1. The 1,000 ohm bell could not call "central" or be called from there. After some spirited correspondence with the manufacturer of one of the instruments, a 1,000 ohm bell in place of the one marked 80 ohms remedied the trouble. It does seem though that a manager who had the faintest kind of an idea of telephone work would know better than this.

Fig. 2. This is a diagram of a toll line in use not a thousand miles from Lake Erie, and the more it is studied the worse it appears, and yet these people actually expect to compete with the "old line" company for business in this section. It seems

to me that the Independent Telephone Association should draw up a standard set of specifications for toll line work right away.

In contrast with the above, I submit extracts from a manager of four years' experience which tells its own story. "We have put in one of the new —— —— —— switchboards. We are also buying the —— —— —— which I think is the best transmitter on the market * * * * We expect to build all our long lines full metallic and will use nothing but the best of everything. If the —— —— telephone is the best we can get, that is the one we want and no other, unless we can find a better one. I am all the time looking for improvements, and want this plant as perfect as the experience I have, and what I can buy of others, can make it." This manager will have to throw away quite a number of old instruments, but he has learned his lesson.

Before putting in your plant, employ a competent superintendent, one who has had practical experience in building, or managing exchanges. Give him carte blanche in regard to details; pay him salary enough to make it worth his while to devote all his time to the work, and have all your plans and estimates made before you start. Then, if you decide to let the work by contract, you will have something tangible for contractors to bid upon, and you will be surprised at the uniformity of the bids and obtain a high standard of work.

LETTERS TO THE EDITOR

The Diagrams in Book Form.

I send under separate cover a copy of a little book containing the report of the Chicago Electrical Association Committee on Standard Diagrams. In order to have these in concise and convenient form for the use of electrical draftsmen and patent attorneys, the Chicago Electrical Association has published this report in convenient pocket form, as it was believed that a majority of electrical engineers would wish to have a set of these diagrams for reference. To cover the expense of printing a nominal price of 10 cents each will be charged. Application for copies should be made to the writer. A mention of these facts in your columns would be appreciated by the association.

J. R. CRAVATH,
Secretary Chicago Electrical Association.
825 Monadnock Building, Chicago.

Exhaust Steam Heating.

Is it correct to let steam of 100 pounds and of 105 pounds pressure expand on the same curve when point of cut-off is the same, as in Mr. Thayer's diagram (Elec. Engr., March 10, 1898)?

Is it not correct, according to Zeuner's and Grashof's formula, that if by ¼ cut-off the back pressure is increased by 5 pounds, the steam pressure must be increased $1.7 \times 5 = 8.5$ pounds to get the same number of horse power?

Will not somebody who has an engine that turns out electric current increase its back pressure 5 pounds by a certain point of cut-off, note how much more steam pressure there is needed to carry exactly the same load, and give the result in The Electrical Engineer? J. S.

New York City, March 10, 1898.

The Selection of Electrical Engineering Diagrams.

IN your editorial of February 24 you give considerable credit to Prof. F. B. Crocker for his paper on conventional diagrams, the editorial being in reference to the recent publication of selected diagrams of the Chicago Electrical Association. It is well to give credit to those to whom it is due, and it is not the desire to lessen the importance of Prof. Crocker's work that the following résumé of the work is sent you:

Of the thirty-five diagrams published by Prof. Crocker only nine similar to those have been selected. On February 3, 1897, Mr. D. W. C. Tanner, who is actively engaged in work relating to electrical engineering and patent office affairs, read a paper, which was published by The Engineer. The reading of this paper resulted in the appointment of a committee whose instructions were to compile a set of diagrams which would bring uniformity into the preparing of patent office drawings and drawings of electrical engineering work in general.

With Mr. Tanner's paper as a basis to work upon, the committee examined numerous patent office drawings, submitted the diagrams in pencil to a number of men actively engaged in patent office work, received suggestions from the Patent Office and finally submitted the diagrams as they appeared in your issue of February 24. These diagrams were approved and adopted by the Chicago Electrical Association.

Mr. Tanner's paper gave a list of sixty diagrams, ten of which were duplicates. The diagrams submitted by the committee were fifty-seven, and of these fifty were diagrams representing with some modifications, the same apparatus that appeared in Mr. Tanner's paper; seven were new diagrams, one of which was a duplicate. Mr. Kempster B. Miller, one of the members of the committee, was for some years employed in the patent office and is an engineer of considerable reputation. Mr. C. Wiler is draughtsman and designer of electrical apparatus, and both had exceptional facilities to obtain expert criticism and suggestions for the work—and much credit should be given to these two gentlemen and to Mr. Tanner, as well as to Prof. Crocker.

In order that as much good and as wide circulation of the diagrams be obtained as possible they were given to the electrical papers before being published by the society. Since they have appeared in the various papers, the Chicago Electrical Association has issued them in pamphlet form, in a handy size for the pocket; which the secretary, Mr. J. R. Cravath, 825 Monadnock Building, will mail to any address upon receipt of 10 cents. The pamphlet is 32 pages, having every other page blank and six blank leaves in the back to permit the user either to make memoranda or paste in other diagrams which may interest him.

At the last meeting of the Association the committee were requested to continue the work of compiling standard diagrams, and any criticisms or suggestions or additions to the present list if forwarded to the secretary will be placed in the hands of the committee for action.

These diagrams represent another step towards a desired end, and by the co-operation of all who are interested the work can be further improved.

THOS. G. GRIER,
Chairman of Committee for Standardizing Conventional Diagrams, Chicago Electrical Association.
March 6, 1898.

The Northwestern Convention Trip.

I beg to thank you for the article in your issue of March 10, relative to the convention plan of the Northwestern Electrical Association. You are, however, mistaken in regard to the length of time involved in the trip and I fear that the article may mislead some who might take the trip when they understand that instead of three weeks' time from New York, both conventions could be taken in and return to New York made in about 12 days at the most. A little less than six days is the extent of the trip from Chicago to Duluth and return—three days on the steamer, two days at Duluth and one night returning from Duluth to Chicago. As it is only 24 hours between Chicago and New York, counting three and one-half days convention for the National and five and one-half days for our trip, two days between New York and Chicago coming and returning, this would make eleven days altogether. I think there are a great many people in the East who would take even two weeks' outing for such a trip, but who would probably not consider it if they were obliged to be absent from their business three weeks. J. M. HILL.

Chicago, Ill.

Paris Exposition of 1900.

Regarding the various government grants for the national exhibits at the Paris exhibition of 1900, the following figures may be of interest: The English Parliament has been asked for a preliminary grant of $375,000 to provide for the expenses connected with the British Section. The United States government had made a treasury estimate of $350,000. The German government has sanctioned a grant-in-aid of $1,250,000.

Interior Illumination.

OF equal importance to the economical generation of the electric current and its distribution over the line is its proper utilization in the form of light, heat and power. The attempts to increase the efficiency of the dynamo by a fraction of one per cent.; to reduce the line loss by increasing the cross section of the conductors or by the employment of high potentials, are only too frequently counterbalanced, or their advantages annihilated by inefficient motor service, the use of cheaply constructed or poorly regulating lamps, or the uneconomical distribution of light. This latter fault has frequently had the effect of prejudicing the public against the use of the incandescent lamp, regardless of its numerous benefits, and it is high time that a prejudice, so unfounded and detrimental, should be removed. In making an experimental determination of this problem, the various conditions, which play an important part, such as size and height of room, color of walls and ceiling, the amount of natural light and the use to which the room is to be put, must be clearly stated; and the results may then serve as safe guides in determining the proper distribution. A series of experiments in this direction, of great value, has lately been made by Mr. I. C. Thompson, the data as to which we publish on another page in this issue. He reached the conclusion that a diffused light is by far the most desirable illumination for a room as it does away with the discomforts and possible injury to the eyes incident upon the use of naked lights of any kind. He further adds that the best shade for diffused lighting would be an inverted conical glass shade with straight sides, having an angular opening of about 90 degrees, ground on the outside so as to transmit more light than an opal shade, and reflect the remainder up against a light colored or preferably white or slightly tinted ceiling, and of such a size as to conceal the bulb itself. This would probably give the highest results per lamp in comparison with other diffusion methods. It scarcely pays to use a 32 c. p. lamp or one of higher power. It would seem better to be able to raise and lower the bulb to obtain a desired brilliancy; certainly 2.6 foot-candles is enough for reading, and a mean general illumination of 0.5 foot-candles for other purposes, and both these can be had by raising and lowering a 16 c. p. lamp in a spherical ground glass shade. Ground glass bulbs give good illumination results, but are still quite intense when looked at. The diffusion surface is not large enough.

Another very interesting and valuable investigation of diffused illumination was made lately by Dr. F. Kermanner and Prof. W. Prausnitz and are recorded in the "Progressive Age." While these experiments were made with Auer (Welsbach) gas burners, the results apply equally well to the incandescent electric light, namely: All downward light as well as the direct radiant heat should be cut off and the entire absence of shadows should be aimed at.

All the results seem to show, however, that diffused illumination is the correct and most agreeable method of interior lighting. Other experiments in this direction may further substantiate this assertion and result in the development of an efficient system of highly diffused light distribution. The lighting of the Columbia University library by means of diffused light from a seven foot sphere rendered luminous by the projected rays of eight powerful arc lamps, and its unqualified success, has already been very potent in making this method of illumination gain favor in this country. It devolves upon the manufacturer of globes and lamps to furnish the correct shape of bulb and globe and to produce an efficient lamp. On the other hand, it must remain the duty of every electric supply house to make the electric light pleasant and ornamental, and the results would soon be manifest in increased earnings of central stations.

Regulating Telephone Traffic.

LAST week we had occasion to comment on the grievance of a Washington doctor who had been made to get change for a large bill so that he could pay for a telephone connection, and who was in a great hurry. It was our endeavor to point out that no matter how urgent his case, the doctor would similarly have had to "split a bill" in order to prepay a letter or telegram, or to get a street car or elevated railroad ride. The incident was supposed to furnish an argument against the existing telephone service in Washington. We fail to see in it any thing but common sense business management. Here is another case of the same kind; a letter from "Syntax" in the New York Evening Post: "While telephone matters are under discussion by our lawmakers, it might be well to call their attention to a little method of extortion that might be checked. I refer to the custom of making a charge whenever a person is called up out of town, even if he is not in. For instance, I call for a man in Paterson, N. J. In a moment his office replies, 'Not in.' That ends the conversation, but I am charged 25 cents just as I would be if I had obtained the desired conversation and occupied the prescribed time. Intelligent management ought to put an end to this practice without appeal to the lawmakers." Possibly "Syntax" is a shrewd business man; perhaps he is unfamiliar with history. In the old postal days, of franks, it was a common trick to refuse a letter. Its mere presentation was all the news required by the person to whom it was addressed. Cannot "Syntax" see that it would be very easy to abuse the telephone system in the same way? How do we know that his friend's clerks were not advised that such a telephone call might convey certain information, without any interchange of words? Or how does "Syntax" know that his friend had not ordered his clerks to say in response to a telephone call, that he was not in? We all do it.

"Syntax" evidently expects—if he is honest in his complaint—that a system costing millions of dollars, employing hundreds of people, shall stand ready at his beck and call, and that if he cannot transact his business right off, the company must stand the brunt of it. How preposterous! Would he ask

a street car company to give him back his five cents, or a railroad company his 50 cents, if on getting to his destination, the man he wanted to see was out? Does he entirely forget the gain of time in reaching his Paterson correspondent? Let him go back to the means of the days when there was no telephone, or even let him stick to the telegraph. He would find that communication under such circumstances will be so slow and irksome, that he would soon want the telephone back, and would pay cheerfully twice the little fee asked for the service.

Combustion Efficiency.

IT has for some time been apparent that not a few electric light stations are earning dividends more as the result of small cumulative economies and stoppages of "leaks" than of any increased efficiency of apparatus. Indeed, this applies more to the steam than to the electrical equipment and the result has been that heaters, economizers, etc., are now very properly considered to be indispensable to economical operation. Unfortunately, however, the ratio of the well designed to the badly designed plants is still an appalling one, and any simple manner of bringing the latter up a notch or two will be welcomed. To reduce the coal consumption at its initial point, namely, in the furnace under the boiler, would seem the simplest way out. It is only too well known that much energy escapes in superheated gases which pass up the chimney accompanied by unconsumed gases, having calorific power, such as carbonic oxide, and hydrocarbon gases, not to mention the unconsumed carbon in the ash. To be calmly told, however, that all these losses can be avoided by closing the ashpit doors and drawing the air required for combustion down the chimney, will bring an incredulous smile to the face of most steam users. And yet the fact stands established beyond question that boiler furnaces are now being operated in this manner and with decidedly increased economy, according to reliable tests. The method by which this result is attained is described by the inventor, Mr. P. J. Schlicht, on another page, and will, we are convinced, excite the keenest interest on the part of every one operating a steam-driven electric plant. Whether or not the Schlicht system of combustion, in its present form, can be advantageously applied to every existing steam boiler may be open to discussion; but if the principle is correct, and there seems now to be no doubt on this point,—then it will probably be only a question of devising proper arrangements to apply it to every style of boiler now in use. For the sake of the entire electrical and steam industry, it is to be hoped that such will prove to be the case.

LITERATURE

AMERICAN GAZETTEER OF POWER PLANTS IN THE PRINCIPAL CITIES AND TOWNS OF PENNSYLVANIA FOR THE YEAR 1897. Cleveland, O., 1897. The American Gazetteer Company. 250 pp. 8 x 11 inches. Cloth. Price, $7.50.

This is a directory containing a list of power plants in all Pennsylvania manufacturing towns exceeding 5,000 population, census of 1890, together with the names of the manager, superintendent and chief engineer of each plant and detailed information as to the power used, number, style and horse power of engines and boilers, number of pumps, dynamos, elevators, etc. To this is added a directory of mechanical, electrical and consulting engineers, contractors and supply houses and other information of interest to power users and engineers.

In addition to the purely directorial contents we notice a chapter of "Useful Information, Tables and Suggestions," for power users; and one on "Electricity for Stationary Engineers." Both chapters are from the pen of Mr. E. P. Roberts, M. E., and contain a large amount of information in very compendious form.

ELEKTROTECHNIK. By O. Hoppe. Essen, 1898. G. D. Baedeker. 175 pages. 5½ x 8½ inches. Cloth. Price, $1.60.

This book is intended as an elementary electrical guide in connection with the machine, mining and smelting industry. It is unique in its presentation of the subject and has evidently been prepared with care and discrimination. The book is well adapted for technical as well as lay readers.

SOCIETY & CLUB NOTES

Chicago Electrical Association.

On the evening of March 4, the above Association discussed the Hunter patents issued December 21, 1897, on the use of transmissions employing alternating current transformers, about which so much interest has been aroused lately. Mr. A. Miller Belfield read a paper on the subject and this was followed by a discussion by Mr. W. Clyde Jones. The patents in question are Nos. 596,041, 596,042 and 596,002. The first one of these is a telephone patent in so far as the drawings are concerned. The second shows a constant current generator with interrupted circuit. The third shows an alternating current generator with step-up and step-down transformers. Mr. Belfield gave no opinion as to the validity of the patents but explained that they were as they stand infringed by every plant using transformers. In discussing the paper Mr. Jones threw some light on the commercial aspect of the case. Two of the patents (Nos. 596,042 and 596,002) are assigned to the General Electric Company. The other (596,041) was not and there was some question whether the claims of this latter could not be construed to cover the present field of alternating current transmission by means of step-up or step-down transformers.

Preparations for the Chicago N. E. L. A. Meeting.

In order to make proper plans and preparations for the Chicago meeting of the National Electric Light Association, President Insull called a meeting of representative electrical men of the Western metropolis, last week, to discuss the subject with him.

Announcement was made of the action of the association in naming June 7, 8 and 9 as the time for the meeting and selection of the Auditorium Annex, as headquarters. The fine banqueting hall has been secured for the sessions. Space will be furnished for exhibits in the hotel parlors and basement. There will be no general exhibit. President Insull announced that the plant of the Chicago Edison Company would be open to inspection at all times during the meeting and that every facility would be afforded members to examine the practical workings of the system. He said that the company would also afford facilities for manufacturers to display their apparatus and specialties in actual operation in the Edison station. The Chicago Edison Company will keep open house for the association during the convention, and the street railway companies and the elevated will co-operate with the lighting interests in giving the visitors an idea of the advancement that has been made in the electrical development of Chicago since the last meeting there. A visit to the drainage canal is proposed. Morning and evening sessions will be held, devoting the afternoons to entertainment and sight-seeing. No definite action was taken on any of the plans suggested, as it was deemed expedient to await the result of President Insull's conference with the Eastern officials of the organization. Another meeting of the Chicago committee will be held March 24, at which time the views of the Eastern members will be presented and definite action taken.

MECHANICAL

The Schlicht Method of Combustion.

By P. J. SCHLICHT.

THE progress made in electricity during the last quarter century has enabled many of the water powers of the world heretofore running to waste to be utilized to good advantage. But the fact remains that the limitations of economical transmission must for an indefinite period continue to leave the steam engine in undisputed sway as the prime source of mechanical power. This means, of course, that coal will be used as heretofore, and as statistics show, in constantly increasing amounts.

It is hardly necessary to enter into the discussion of the losses entailed in modern methods of steam generation. It seems, however, that of all the sources of loss that to which least attention has been paid is the loss entailed by the improper burning of the fuel on the grate. These losses may be stated broadly to be first those due to improper oxidation or combustion of the fuel, and, second, those due to the superheated gases escaping at the chimney.

In seeking to reduce and, if possible, entirely avoid one or both of these causes, I was led to the consideration that the prime source of furnace inefficiency was due to the introduction of cold air into the glowing bank of coal, in quantities far in excess of that required for the actual combustion of the fuel. How to introduce just the required quantity of heated air into the furnace was, therefore, the problem which I set before me.

Without going through a vast amount of preliminary work I may state at once that I discovered that a current of air and a current of combustion products will flow in contact without any substantial intermingling, and if a current of air is properly introduced into a chimney or flue through which hot products of combustion are escaping the current of air will flow to the place of combustion in a direction opposite to that of the current of products. The current of air will, however, gradually become hotter, while that of the products of combustion will gradually become colder. The heat thus imparted by the hot escaping gases to the colder entering air is thus utilized to advantage.

The general manner in which the plan above outlined is carried out in practice is illustrated in the accompanying engraving. As will be seen the top of the chimney is provided with a sleeve which extends for a short distance above and below the chimney structure proper. The hot gases pass out through the centre of the sleeve, while the air is drawn in between the inner wall of the chimney and the sleeve. The course of the two currents of inflowing air and escaping products of combustion are indicated by the arrows. Of course it will be understood that with the writer's system the ash-pit doors are kept constantly closed or nearly closed, all air necessary for combustion coming down through the chimney or by way of the chimney flue.

But there is another and most important advantageous feature connected with this method of combustion and that is, that the air supply is automatically regulated to that actually required for the oxidation of the carbon. This automatic regulation is the result of the interdependence of the actions of the chemical operations within the place of combustion and of the inflowing air and outflowing products of combustion. The intensity of combustion and the volume, temperature, density, and general conditions of the current of products of combustion are affected and governed by the like conditions of the air current, and the volume, temperature, density and general conditions of the air current are themselves directly affected and governed by the intensity of combustion and the volume, temperature, density and general conditions of the current of combustion products. The propulsive force is the pressure of the atmosphere, and since this pressure is practically constant the flow of air to the place of combustion will be in all particulars uniform unless there are variations in the general conditions of the column of escaping products of combustion within the stack or duct.

And now as to the practical results obtained with my system of combustion.

Various tests made with stoves convinced me that I had an invention of great value for the combustion of coal in ordinary domestic combustion appliances; many of the tests on stoves and furnaces showed from 33⅓ to 50 per cent. economy in the production of the same number of heat units available for heating or cooking purposes; but what its practical limitations might be when applied to steam boiler furnaces had yet to be ascertained. Such factors as size of chimney, area of grate and of heating surface, and kind of fuel, had all to be taken into account.

The first experimental application of this system to a steam plant was made at the Eastern Brewery, located at Meserole street and Bushwick avenue, Brooklyn. A contract was made on the basis of the saving effected, as shown by decreased consumption of coal per barrel of beer, before and after the application of the system. A careful and accurate account of the coal was kept, and a check was given in payment. Since this application of my method of combustion many improvements

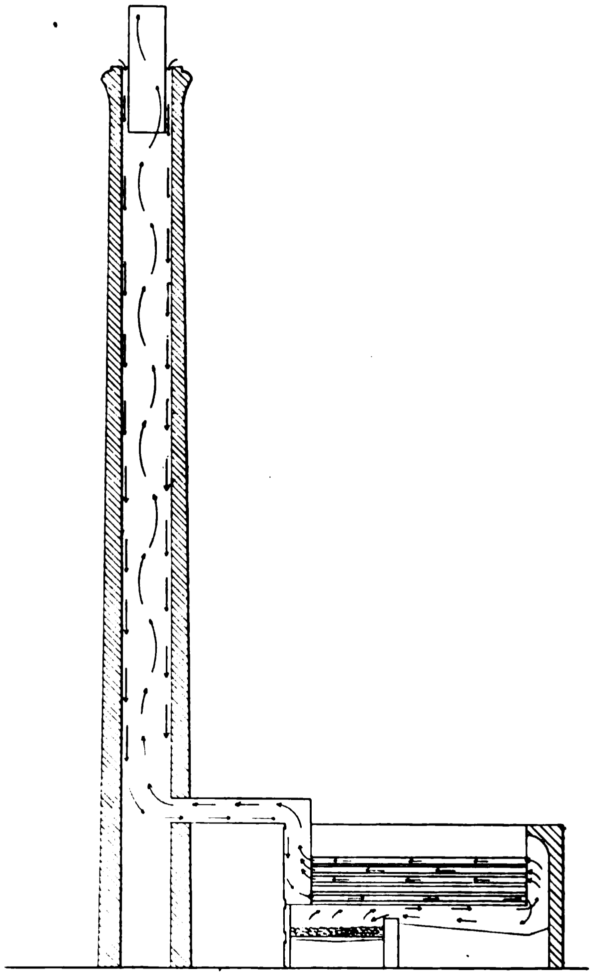

DIAGRAM SHOWING THE SCHLICHT METHOD OF COMBUSTION.

have been made, but the system still operates satisfactorily at this brewery. This was in May, 1896.

Careful evaporative tests were made, under the direction of skilled engineers, for the purpose of determining the real saving shown. The Schlicht Heat, Light and Power Company, that had acquired my patents, decided to carry on for a period of time a series of practical experiments on plants in actual operation, to ascertain the relation of different boilers and different fuels to the system.

Before proceeding any further with the history of the growth of this invention, I would briefly state what I claim to have found to be the salient features of the system, in its application to domestic as well as industrial plants.

First. A saving is made by heating the air by contact with products of combustion after they have passed the sphere of useful work, instead of heating the air at the expense of the fuel.

Second. A saving is made by feeding air heated by the pro-

ducts of combustion on top of the fire in automatically regulated quantities.

Third. A saving is made by excluding the large amount of surplus air fed through the grate bars in ordinary practice.

Fourth. Hydro-carbons and other combustible gases, which frequently escape before they are consumed for lack of oxygen, are wholly consumed in the combustion chamber.

The industrial value of different fuels is usually estimated by the amount of fixed carbon they contain. Our experiments, however, with coals high in volatile matter (which is a characteristic of the coals of the West), show that we are enabled to get a very high efficiency from them.

That calorimeter tests are unreliable in determining the industrial value of coals that have large percentages of hydrogen was shown in a paper read some time ago before the American Society of Mechanical Engineers, by Dr. Chas. E. Emery, in which he cited a coal that showed by calorimeter test some 24,000 heat units, but which in practice was not equal to a good Lehigh coal with half the heat units. Of course the percentage of fixed carbon in the former was quite low.

The results of several carefully conducted tests at Rochester, N. Y., under the direction of H. M. Reichenbach, engineer and chemist, with a coal having about 50 per cent. of volatile matter, showed a gain in evaporation of 44 per cent. This was at the plant of the Photo-Materials Company, which was selected by Mr. Reichenbach because it was a model plant. The significance of this test is obvious when we consider the great chimney wastes in connection with these fuels.

The following evaporative tests will give engineers some idea of the efficiency of the system in practice.

At the plant of the Barber Asphalt Paving Company, Long Island City, several carefully conducted evaporative tests showed the following results in evaporation:

	With Schlicht System.	Without Schlicht System.
Water evap. per lb. of coal from and at 212°.	12.96	10.79

An increase in evaporation of 20.1 per cent.

At the steam plant of the Hon. James B. Baxter, Portland, Maine, several tests were conducted with Pocahontas coal, as also with a mixture of one-quarter Pocahontas and three-quarter anthracite screenings, with the following results:

	With Schlicht System.	Without Schlicht System.
Water evap. per lb. of coal from and at 212°.	12.45	9.48

A gain of 31.3 per cent.

Burning the mixture of Pocahontas and screenings, costing \$2.08 per ton, as against \$3.80 per ton, a gain in evaporation was made of 3.2 per cent. over Pocahontas coal without the Schlicht system, or an economy in cost of coal per horse-power of 47.2 per cent. It was impossible to burn this mixture in this plant without the system unless forced draft were used.

At the Copley Square Hotel, Boston, it was impossible to burn pea coal and produce the required steam for an electric lighting plant that had been installed; consequently it was found necessary to burn Cumberland coal. With my system in use, the burning of three parts anthracite screenings and one part bituminous coal was made possible, with a saving to the proprietor of some \$200 per month.

A test made at Manchester, N. H., under the supervision of Capt. Chas. H. Manning, superintendent of the Amoskeag Mills, on the Manning boiler, using Reynoldsville coal, showed a gain in evaporation of 21.23 per cent. This was at the plant of Crafts & Green, shoe manufacturers.

Capt. Manning then selected the steam plant of the Langdon Mills, having a chimney too small for carrying off the products of combustion, the chimney having been built for two boilers, but to which three boilers more had been added. The tests were conducted by Prof. Lionel S. Marks, under direction of Capt. Manning and showed on a four days' trial an increase of evaporation in pounds of water from and at 212 degs. per pound of dry coal of 4.5 per cent. in favor of the Schlicht method.

Capt. Manning in a letter states that the chimney area was very small and that the plant was showing a very good efficiency before and that he did not expect there would be any beneficial results in this case.

A test taken at the steam plant of the distillery of Fleischmann & Company, showed a gain of 15 per cent. in evaporation, and at a subsequent test for capacity only, the Schlicht method developed a horse-power 8 per cent. in excess of the highest ever previously developed.

The above-mentioned are a few of very many tests that have been taken and are quoted as representative of the various types of boilers upon which the method has been tried.

Various experiments carried on demonstrated the fact that this system of combustion produced more heat than could be converted into useful work by the boilers. It required nearly a year of experimentation to obviate this difficulty.

The illustration given shows only one of the forms of application, as "deflectors" are applied not only at the top of chimneys, but as well in the horizontal flues and uptakes, the mode and place of application being wholly determined by the type and number of boilers, arrangements of flue and chimneys and other characteristics of the plant to be equipped. For house heating and other domestic purposes the flue application is almost exclusively used.

EDUCATIONAL

Electrical Engineering at Columbia University.

GENERAL PLAN OF BUILDINGS.

THE new buildings of Columbia University are located at 116th street, between the Boulevard and Amsterdam avenue, on the highest part of Morningside Heights, midway between Grant's Tomb and the new Episcopal Cathedral, commanding a view of the Hudson on the West and the Harlem River on the East. Thus situated in a great metropolis, the University secures the manifold advantages which that fact gives it, and at the same time is sufficiently lifted above the hurry and noise of the city to have the collegiate atmosphere. This effect is still further increased by the fact that the grounds between the various buildings form a plateau about twenty feet above the level of the grounds and streets outside of the group of buildings. By this arrangement great economy in space is secured, since it gives two more floors to each of the buildings situated around the edge of the plateau, their basements and sub-basements being above the level of the surrounding grounds.

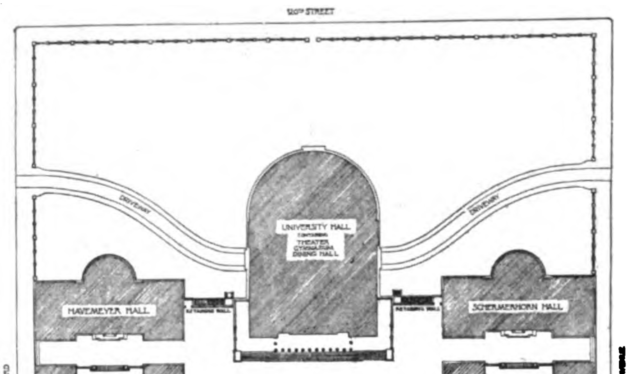

FIG. 1.—PLAN OF BUILDINGS.—COLUMBIA UNIVERSITY.

The raised level between the buildings also enables tunnels to be constructed which connect the various buildings with the central power plant in the University Hall. Through these tunnels all the steam and gas pipes as well as the electrical conductors are carried and the cartage of coal, ashes, and supplies takes place.

In this way these important practical matters are very conveniently carried on below ground as far as the college is concerned, but at the same time above the street level. Each building is provided with an elevator chiefly used for carrying apparatus and supplies to and from the various laboratories, lecture rooms, and museums. Thus it is an easy matter to transport even heavy apparatus from any room in the university to any other room. To still further facilitate this service, the door sills are entirely omitted in most of the rooms, so that a truck can be run about the buildings without jarring that which it carries, enabling apparatus to be arranged in the laboratory for use in the lecture rooms.

ment of Architecture is temporarily housed in the Chemistry Building, which has more than sufficient space for present needs. Schermerhorn Hall, the Natural Science Building, contains the Departments of Geology, Minerology, Biology, etc., and their extensive collections. The Physics Building, which also accommodates the Department of Mechanics and Astronomy, is designed and equipped according to the most modern methods for teaching and investigating physical science.

It is a striking fact, characteristic of modern tendencies, that all four of the new buildings, besides the Library and University Buildings which are used for general purposes, are devoted entirely to science; and three of them are especially important in their relation to Electrical Engineering. Hence the Course in Electrical Engineering at Columbia, which has already gained for itself a prominent position in electrical education in this country, has been materially benefited by the removal of the University to its new site. The principal improvements consist in a considerable extension of space and equipment in the Electrical Engineering laboratories, as well as in those devoted to Mechanical Engineering, Physics, and Chemistry.

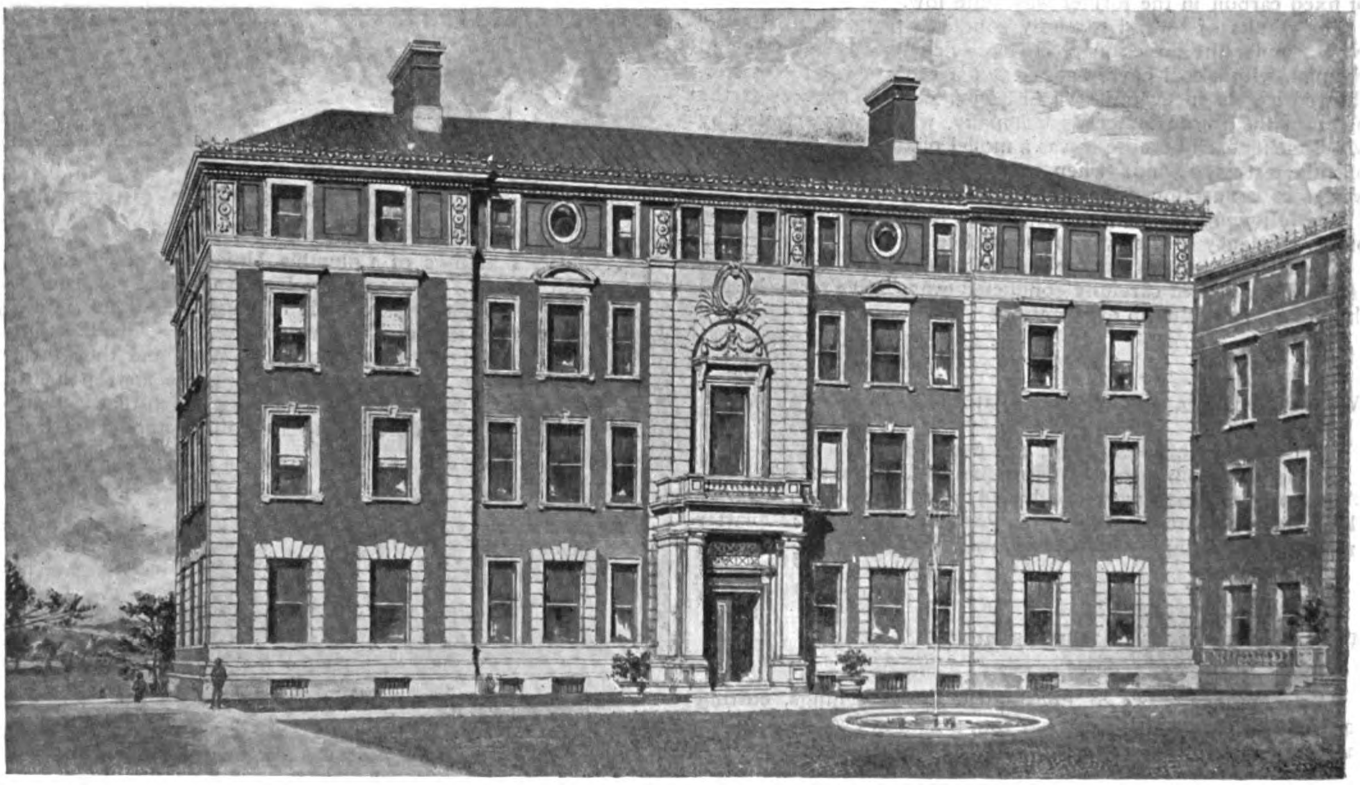

FIG. 2.—ENGINEERING BUILDING, COLUMBIA UNIVERSITY.

The location of the various buildings at the new site is shown in the general plan,[1] Fig. 1, the magnificent Library, presented by President Low, being the central one and easily accessible from all the others.

University Hall is the other general building, containing the power plant, gymnasium, academic theatre, etc. There are also four new buildings, respectively devoted to Engineering, Chemistry, Natural Science and Physics. Two old buildings will be used for the present by the Departments of Ancient and Modern Languages, and Mathematics.

The Schools of Law, Political Science and Philosophy are located in the Library Building, bringing them within convenient reach of the books upon which they are especially dependent. The Medical School will remain at Fifty-ninth street, between Ninth and Tenth avenues, where it is well provided with buildings and equipment. All the other departments of the University, including Barnard College and the Teachers' College which are affiliated with it, have removed to the new site.

The Engineering Building, Fig. 2, with its annex, contains the Departments of Electrical, Mechanical, Civil, and Mining Engineering. Havemeyer Hall, the Chemistry Building is the home of one of the largest and best equipped chemical schools in the world, having been designed by Prof. Chas. F. Chandler and the officers of his department after a careful study of the principal colleges and technical schools in this country and abroad. The Depart-

[1]Only those buildings designated by names are already erected.

THE ELECTRICAL ENGINEERING COURSE.

The regular four-years' course, leading to the degree of Electrical Engineer (E. E.) is designed for the education of professional electrical engineers who intend to devote themselves to the practice of this profession, either as teachers in colleges and scientific schools, or as engineers, managers, or experts in manufacturing or other industrial enterprises.

The course of instruction includes not only all important branches of theoretical and applied electricity, but also the other collateral sciences, which have been found by experience to be required by the electrical engineer, such as mathematics, physics, chemistry, drawing, analytical mechanics, mechanical engineering, including a thorough course in steam and other engines, as well as transmission machinery and shopwork. General engineering, including construction in masonry, iron, steel, and wood, also form part of the course.

Hence the graduate in the course in Electrical Engineering is provided not only with a thorough knowledge of the principles and practice of electricity, but also with such a broad and liberal education in the allied sciences as will prepare him for every demand that is likely to be made upon him in after life in connection with his profession, and will also enable him to become an investigator. The instruction is by lecture, recita-

tion, laboratory, workshop, and drawing room practice, wth periodical examinations. Special attention is given to new methods and forms of apparatus in order that the student may be brought fully abreast of the rapid progress of electrical science and practice. Frequent visits are made to the numerous electrical factories, stations, and other establishments in and about New York.

EQUIPMENT.

The offices, laboratories, lecture and other rooms of the Electrical Engineering Department are in the south end of the Engineering Building. In the sub-basement are located the storage battery and photometer rooms; the former contains a battery of 70 cells, to be used for efficiency and output tests and

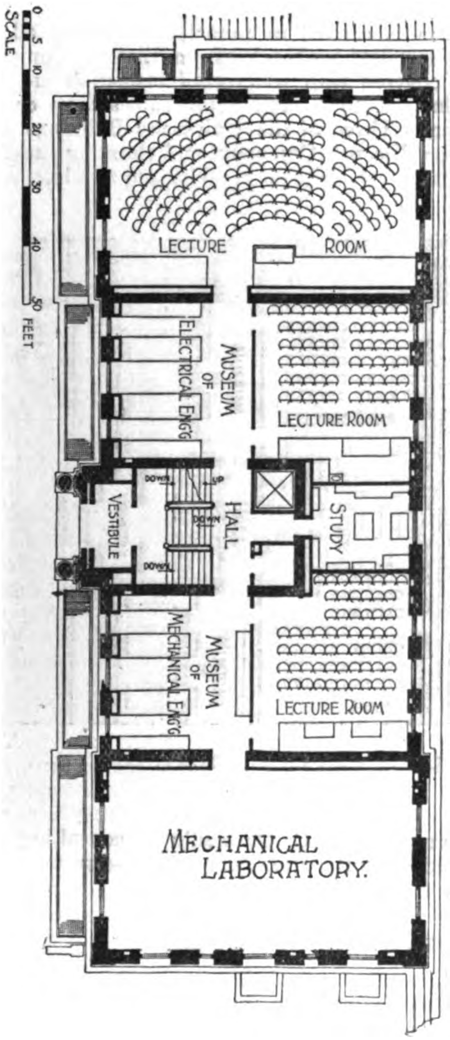

FIG. 3.

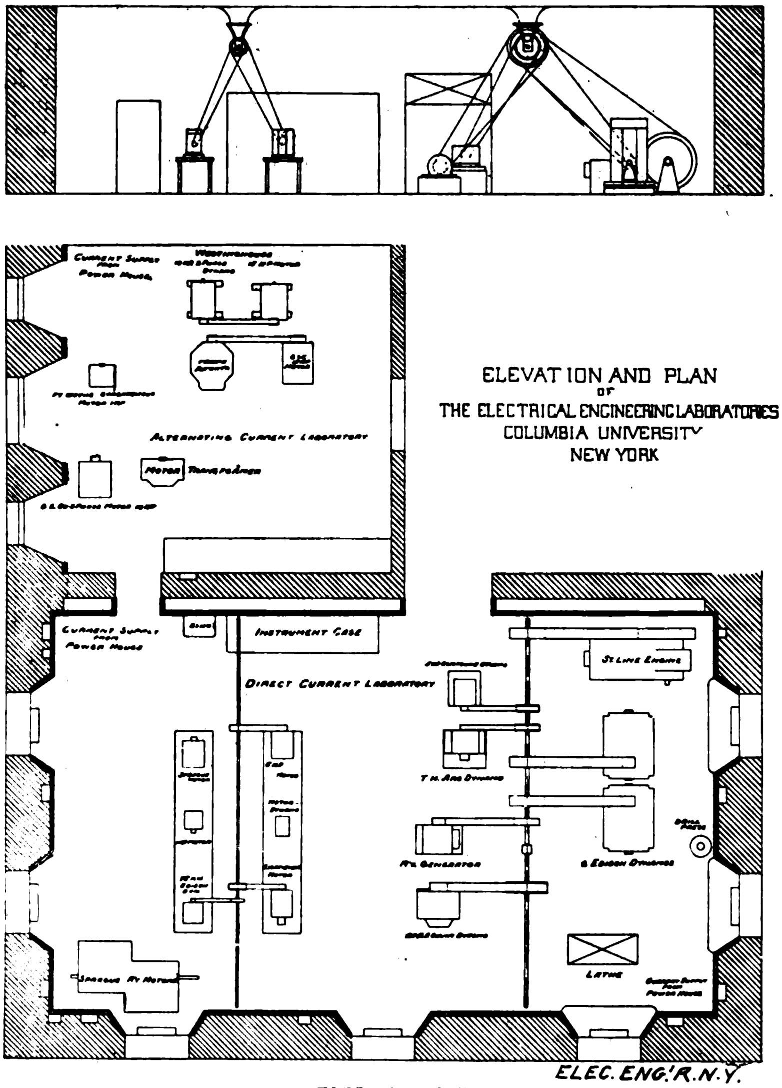


FIGS. 4 and 5.

MECHANICAL AND ELECTRICAL ENGINEERING LABORATORIES.—COLUMBIA UNIVERSITY.

also as a source of steady potential and current. The photometer room is equipped with all necessary apparatus for determining the candle power of arc and incandescent lamps as well as other sources of light. In the basement are situated the two machine laboratories, the larger containing the direct current machinery, while the smaller accommodates the alternating current apparatus. These are shown in cross section and plan in the accompanying illustrations, Fig. 3 and 4. In the former, a 50 h. p. high speed steam engine drives two lines of shafting, carrying pulleys controlled by friction clutches, to which the various machines are belted. The arrangement of the engine and shaft is such that two dynamos of 30 k. w. each can be connected to the engine, or either or both of the two machines may be used as motors to drive the line shaft, the current being obtained from the electric light and power plant of the University. In this way the breaking down of the motive power is rendered almost impossible and an excellent demonstration of the two methods of driving is made.

The various dynamos which are belted to the line shaft include examples of 115, 230 and 500 volt constant potential generators, constant current arc lighting dynamos, and other typical machines. Several types of stationary and railway motors, as well as motor-dynamos are also placed in this room. Machine and hand tools are provided in one corner of this laboratory for making and repairing apparatus, attachments, etc. Complete sets of ampere and volt meters, speed indicators, transmission and absorption dynamometers, etc., are available for testing the various dynamos and motors. The smaller machines are mounted upon two long heavy tables, as represented in the illustrations, which brings them to a convenient height and affords space for instruments, note books, etc.

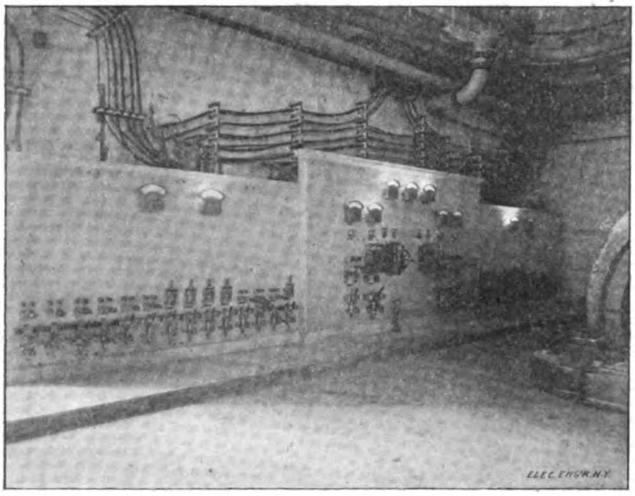
In the other machinery laboratory, the alternating current apparatus is placed, including single and polyphase generators, induction and synchronous motors, as well as various types and sizes of transformers. Each generator is driven by its own electric motor, enabling its speed to be independently regulated.

LECTURE ROOMS AND ELECTRICAL LABORATORIES.

On the first floor, a plan of which is shown in Fig. 5, are situated the smaller lecture room (seating 70), ordinarily used for class work, and the larger lecture room (seating 150) for combined classes. In the Chemical Building, immediately adjoining, a still arger lecture room (seating 350) is available for meetings and public lectures. All of these rooms are provided with an ample supply of electrical energy of different forms as well as gas, water, and other facilities to enable experimental demonstrations to be conveniently and effectively performed. For example, dyanmos, motors, and other apparatus of practical size are shown in actual operation to illustrate the lectures, this being made a special feature of the instruction.

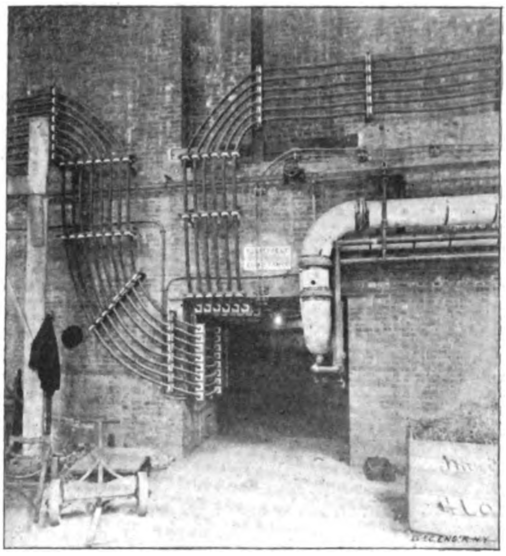
The museum contains cases for the collection of apparatus, models, materials, etc., relating to electrical engineering. This museum adjoins the lecture rooms so that its contents can be conveniently used for illustration.

On the third floor are located the large instrumental laboratory, the research room, and the studies of the officers. The



MAIN SWITCHBOARD, COLUMBIA UNIVERSITY POWER PLANT.

laboratory contains a number of tables on which the instruments are permanently set up ready for use. These include various forms of galvanometers, ampere balances, standard cells and resistances; apparatus for measuring inductance, magnetic permeability, hysteresis, and leakage; laboratory standard volt and amperemeters; telegraph, telephone, and electric signaling systems; thermo-electric and electrical heating devices; Röntgen ray apparatus. The research room is used for special post-



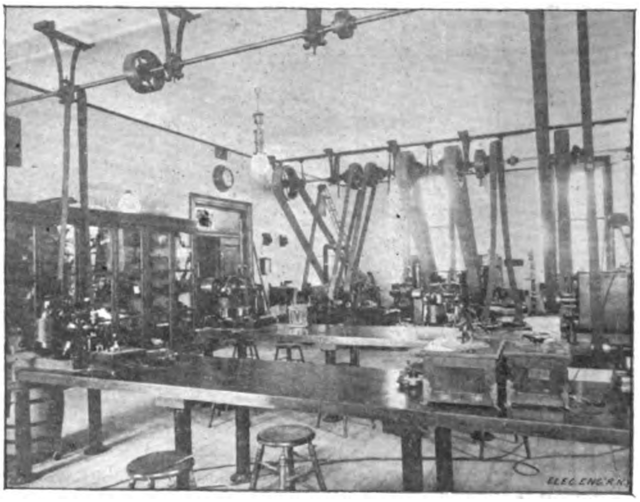
FEEDERS EMERGING FROM TUNNEL, COLUMBIA UNIVERSITY.

graduate and thesis work, and is fitted up according to the lines of investigation that are being followed.

THE POWER PLANT.

A most important facility is the large and reliable supply of electrical current which is afforded by the central power plant of the University. This consists of boilers having an aggregate capacity of 2,000 h. p., two low speed Allis-Corliss engines directly connected to two Crocker-Wheeler dynamos of 100 h. p. each, and two high speed engines directly connected to two Crocker-Wheeler dynamos of 100 h. p. each. Space has been reserved for a fifth machine of 400 k. w. capacity. Running along the east wall of the dynamo room is the switchboard, of white marble. The right hand panel controls the lighting, and the left hand, the power circuits. The centre panel has the generator switches mounted on it. The bus bars on the generator panel are divided into three sections with two bus junction switches so that light and power may be supplied independently of each other. The switchboard was built by the Incandescent Arc Light Company. This electrical generating plant, having a total capacity of 750 h. p., and illustrating the latest practice in electrical engineering, furnishes current for electric lighting and for driving the motors and fans used in ventilating all of the buildings. Special conductors are also laid to convey to all the laboratories as well as lecture rooms of the Electrical Engineering Department an ample supply of current for experimental work.

The feeder system is carried in tunnels connecting all the buildings and was installed by the Western Electric Company. The heavy cables covered with waterproof insulation are supported on porcelain insulators. The figure shows them emerging from the tunnel. Three of the University Buildings were wired by the Tucker Electric Company, and three by the New York Electric Equipment Company. The entire electric in-



VIEW OF ELECTRICAL LABORATORY, COLUMBIA UNIVERSITY.

stallation was planned by M. C. O. Mailloux, consulting electrical engineer, and its installation was carried out under the direct supervision of Mr. C. E. Knox.

THE PHYSICS DEPARTMENT.

The Physical Laboratories and lecture rooms occupy four floors of the Physics Building on the eastern side of the University grounds. The building is supplied with all ordinary conveniences, including electricity for power and light, compressed air, and steam. There is a vertical shaft 95 feet high with gas, electric, and water outlets at every ten feet. In the sub-basement a constant temperature room is placed 12 feet below the surface of the ground. A platform on the roof is available for meteorological observations, an instrument room being directly below. There are two lecture rooms, a library, an apparatus room, and laboratories of various kinds.

The general elementary laboratory includes in its equipment, linear and circular dividing engines of various designs. For measurements of mass there are provided balances with weights, specific gravity apparatus, hydrometers, aerometers, and the various forms of vapor density apparatus. Standard barometers, pendulums, and apparatus for studying elasticity, are provided; also apparatus for the study of sound.

Thermometers and apparatus for their calibration, and determination of zero and boiling points, are supplied; also apparatus for determination of coefficients of expansion, for latent and specific heats and calorimetry.

The optical rooms are furnished with spectrometers of different designs, spectroscopes, telescopes, microscopes, sets of lenses,

prisms and gratings, optical benches, photometers, and apparatus for calorimetry, polarized light, spectroscopy.

In the rooms devoted to electricity are galvanometers of various patterns, high and low resistance, ballistic and damped; electrometers, magnetometers, standard cells, resistances, rheostats, and bridges of all types; condensers, batteries, keys, arc and incandescent lamps, amperemeters and voltmeters.

THE MECHANICAL ENGINEERING DEPARTMENT.

The Mechanical Engineering Department is located in the Engineering Building and in the Annex, the space and equipment provided for it being greatly increased at the new site. This improvement is made not only on account of the importance of this branch in the Electrical, Civil, and Mining Engineering courses, but also because regular courses in Mechanical Engineering have now been opened at Columbia for the first time, the space at the old site not having been adequate for the purpose. The department has the following equipment:

The Wood-working and Machine Shops are located in the Teachers College, 120th street. For wood-working there are carpenter's benches with their kits of tools, speed-lathes, saw-benches and planers. For forge and blacksmith work there are forges with anvils and tools, a Bradley hammer and a Billings & Spencer drop-press. For metal-working there are engine-lathes with swing from twelve inches to twenty inches, planers, shapers, drill-presses, a universal milling machine, universal grinding machines and a Jones & Lamson turret-lathe.

The Testing Laboratory is equipped with high grade testing machines for tensile, transverse, torsion, and compression tests. Their designs are of diverse types to give wide experience in handling, and they are fitted with the best and newest appliances for observing and recording deformations of test-pieces. The Emery testing machine of 150,000 pounds capacity is used as a standard of reference.

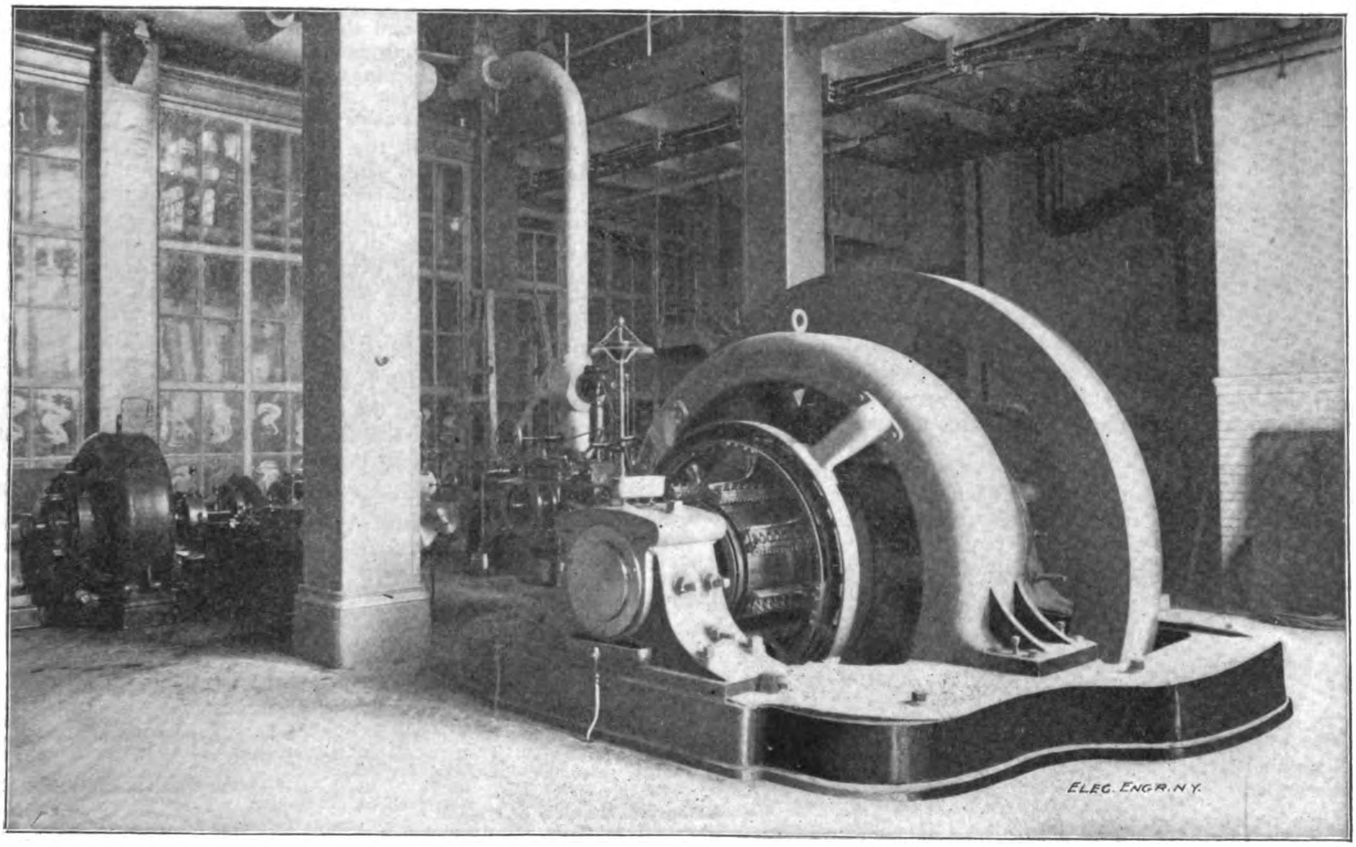
The Mechanical Engineering Laboratory is well supplied with dynamometers of transmission and absorption types, with oil testing appliances, speed recorders, tachometers, weighing and measuring apparatus, anemometers, gauge testers, and the like, and representative machines and mechanisms for calibration and tests of efficiency.

The Steam Engineering and Motive Power Laboratory has an extensive series of indicators, with appliances for calibrating and standardizing them, test gauges, thermometers, calorimeters, pyrometers, and apparatus for boiler and engine tests. A triple expansion steam engine of the Reynolds-Allis-Corliss design is arranged to work as an experimental steam engine by making it a three-stage air compressor, and having all facilities for the accurate measurement of efficiencies. A full line of boiler feed injectors is mounted for display and experiment. Steam engines of various other types, steam pumps, a 10 h. p. De Laval steam turbine, hot air and gas engines are at hand, and surface condensing appliances as well. The department has also a cross compound two-stage air compressor, the cross compound steam end of which with reheater, combined with the cross compound air end with intercooler, makes a most complete example of applications of thermo-dynamic theory to practice. This laboratory is known as the Allis Laboratory, and was founded in memory of the late Edward P. Allis.

The Hydraulic Laboratory contains tanks, weir-notch equipment, gauges, current meters, water meters, and motors for test and experiment. Constant pressure is secured by air pressure upon the water in a closed tank, thus doing away with a standpipe. For heavier pressures, above 100 pounds per square inch, an adjustable accumulator is used. Pumps of large capacity give the necessary quantity of water for orifice tests and drills in hydraulic engineering. The equipment of this laboratory was presented as a gift to the University as a memorial of the late Henry R. Worthington, of New York City.

The Drawing Academies are particularly well lighted and of large extent, and are fitted with the best forms of drawing tables and furniture, as well as extensive collections of patterns, models and illustrative drawings, blue prints, photographs, and prints, which are useful as copies, and for training in design. Sectional models of actual machines and structural material are abundant, and for the study of projection, stone cutting, and warped surfaces, there is a set of the Ollivier models, in which the elements of surfaces are represented by tense threads. In connection with the Drawing Academy is a room for blue printing and other solar work, and a photographic dark room.

The Cabinets or Museum Collections of Mechanical Engineering exhibit models of mechanical movements, mechanisms, and gearing, also material which has failed in service and under test.



DYNAMO ROOM, COLUMBIA UNIVERSITY, NEW YORK, POWER PLANT.

Specimens of apparatus and materials for practice are also included.

The Chemical Department occupies Havemeyer Hall, which is located at the northwestern corner of the group of buildings. It contains several chemical lecture rooms, fully supplied with apparatus and instruments and all modern facilities for the experimental illustration of the different lecture courses. The museum of general inorganic and organic chemistry, and of the chemical arts, contains the elements and all their more important compounds; representative sets of specimens of all classes of compounds, materials, and products, together with models, pictures, and diagrams. The qualitative laboratory is provided with tables, reagents, and all the necessary facilities to enable each student to become familiar with the reactions of the different metals and salts. The student is required to repeat all the experiments of the course of instruction at his own table in this laboratory. The quantitative laboratory is provided with tables, reagents and all the necessary apparatus and instruments to enable the student to actually execute quantitative analyses. There is also a laboratory specially fitted up for electro-chemical work.

The theoretical as well as practical branches of Electrical Engineering are taught by Professors F. B. Crocker and M. I. Pupin, and Messrs. G. F. Sever, W. H. Freedman and S. G. F. Townsend.

Municipal Electric Lighting.[1]—IV.

BY PROF. JOHN R. COMMONS.

FEWER "OUTAGES" UNDER MUNICIPAL OWNERSHIP.

IN the matter of "outages," too, the records for private plants are usually quite imperfect. Deductions are made from the contract price before payment is made by the city; but here is room for the political influence of the companies. The policemen are usually required to report outages, and in Syracuse the convenient practice obtains of reporting to the electrical company, which then reports to the city on their own outages.

For the City of Detroit the following comparison is made by the Public Lighting Commission of the outages under private and under municipal operation.

TABLE IV.

CONTRACTOR OPERATING 1,279 LAMPS, 1893-4.

Month.	No. lamps out.	Hours out.	% Lamps out.	% Hours out.
October	1,319	6,825	3.326	1.500
November	1,372	11,988	3.575	2.455
December	2,710	20,485	6.835	3.867
January	787	4,304	1.985	0.834
February	2,898	17,642	8.092	4.131
March	1,177	5,317	2.943	1.270
April	1,729	8,930	4.506	2.551
May	1,273	4,833	3.211	1.543
June	1,679	6,102	4.375	2.186

CITY PLANT OPERATING 1,483 LAMPS, 1895-6.

Month.	No. lamps out.	Hours out.	% Lamps out.	% Hours out.
October	152	1,040	0.335	0.201
November	95	774	0.266	0.137
December	138	940	0.300	0.154
January	47	372	0.116	0.062
February	42	301	0.098	0.059
March	28	235	0.061	0.048
April	84	350	0.179	0.088
May	63	283	0.138	0.080
June	25	137	0.056	0.042

It is also true that a steady improvement has been shown for the second year of municipal ownership, 1896-7, both in absolute amounts and relatively as well. A comparison of individual months shows the same superiority of public over private ownership. Not only does the city of Detroit get a steadier light but the brilliancy of the same is greater than that obtained from private corporations. The amount of the current used is maintained at 9.6 amperes, and the lamps burn at their full rated candle power.

Such facts as these not only may give us confidence that municipal enterprise does better work than private companies in the field of electric lighting, but they also lead us to look with suspicion upon any statistics favoring private operation which are based upon candle power cost, even if conscientiously compiled.

FAVORABLE COMMENTS OF OPPONENTS.

Turning now to the investigation of Mr. Foster we are at once impressed with its marks of candor and ability. Writing, as he does, under conditions opposed to public ownership, it is a matter of moment that he should publish such statements as these:

"The tone of all communications from those favoring the municipal side seems to have taken it for granted that the results shown would tell that side sufficiently well, and it must be admitted that in quite a number of cases such is the fact." Commenting upon the fact that the average cost per lamp of 2,000 candle power for installing a municipal plant complete is shown to be $249.30, and that this is very close to the price quoted by manufacturing companies to private purchasers, he remarks; "This is seeemingly contrary to the commonly made statement, that municipal plants are not bought as cheaply as private, said to be due in a measure to 'jobs.' Perhaps these 'jobs' may be offset in the purchase of private plants by the commission sometimes paid some member of the company." Again, he says: "In all fairness it may be said that the much-vaunted better management in private hands does not exist. In fact, the men in charge of city plants compare quite favorably with those in charge of private plants of similar size." These statements seem to show that in his own mind, whatever conclusions others may draw from his figures, his careful investigation has not proven what its projectors intended, viz., a demonstration of the greater economy of private electrical lighting; and his figures themselves, as will be shown below, when rightly examined in the light of the facts and of statistical rules, are not only not a disproof of the claims of municipal ownership but a strong testimony in their favor.

THE UNITED STATES AND FOREIGN COUNTRIES CONTRASTED.

Mr. Foster agrees with what I have already stated above with reference to operating costs, i. e., that there is comparatively little disagreement among the returns made by different investigators. In order to show this, he gives the following table from which fixed charges have been excluded.

TABLE V.

COMPARISON OF OPERATING EXPENSES PER K. W.

	Labor per k. w.	Fuel per k. w.	Supplies and offices per k. w.	Total cost per k. w.
14 American municipal stations, street lamps only.	$ .025	$1.0173	$ .0161	$ .0585
5 American municipal stations, incandescent.	.0244	.0226	.0126	.0596
1 American municipal station arc, new..	.0317	.0199	.0069	.0585
6 American private stations, mixed output of 5,300,000 k. w.	.....	.0095	.....	.0473
5 German stations, output 1,807,900 k. w.	.0218	.....	.....	.0469
23 English stations, average, Crompton..	.0144	.0222	.0194	.0560
Ideal English stations, Crompton	.0040	.0054	.0170	.0264
Lowest items in 23 stations, Weaver....	.0074	.0126	.0173	.0373

Mr. Foster says in commenting upon these figures: "Attention must be called to the remarkable agreement of cost in the American municipal stations, and the average of the English stations, and again to that of the six large American stations and the German average; both of the last two are equipped with large units in engines and dynamos, which probably accounts for the cost being lower than in the others." He says also, "The item of labor is the one division of operating expense in which it is claimed the greatest expenditure will be made in municipal plants. If the average here shown may be considered accurate within reason, this belief is largely a myth, for (with the exception of Chicago where labor is 53 per cent. of the operating expenses) the percentage for labor is less than usual in private plants. Either very low wages and very poor help are the rule, or the item has been classed wrongly."

It is when we come to the matter of "fixed charges," including interest, depreciation, insurance and taxes, that we find the widest divergences between the advocates and opponents of municipal ownership. It is here that almost the entire difference

[1] Municipal Affairs, Dec., 1897. A Reply to R. R. Bowker. See Elec Engr.

between the figures of Foster and Parsons is to be found. Mr. Foster estimates interest uniformly upon the entire cost of the plant up to date at the uniform rate of 6 per cent., unless the officials have given him a different rate. As the actual rate is thus given in only sixteen of the thirty-four cities whose returns he has tabulated he has guessed at the rate of eighteen. In every case where I have been able to find the actual rate as against his guess, the rate is 4 per cent. And it may be stated as a general rule that the smaller cities in the East can borrow money without difficulty at 4 per cent., getting a premium on the bonds at this rate, and in the middle West no higher rate than 5 per cent. is paid, rising to six and seven on the Pacific coast. Chicago borrows money at 3 per cent., whereas Mr. Foster's gross interest charge for that city figures out 4.2 per cent. A difference of 2 per cent. on the average investment of $250 per arc light makes a difference of $5 per year per arc in the aggregate cost.

INTEREST COMPUTED ON OUTSTANDING DEBT ONLY.

Prof. Parsons estimates interest not on the total cost of the plant as does Foster, but upon the actual amount of bonds outstanding. Therefore if no debt has been incurred for the electrical plant, or if the debt has been paid, interest entirely disappears from his calculation of cost. In cities without a debt on the plant, therefore, the difference between the total costs of Foster and Parsons would average $15.00 per arc lamp per year.

Parsons' reason for including interest not on the entire cost of the plant, but only on the outstanding debt, is that in municipal ownership the people pay interest to themselves, except where a debt makes a creditor in effect part owner, and therefore, to calculate interest on the total cost in excess of the debt would be only to take out of one pocket and put into another. This reason does not appear sound. Taxpayers and consumers are not the same individuals, except in street plants alone. The true economic principle seems to be as follows:

The taxpayers must pay for street lighting either to a private company or to a municipal plant. If the cost of the lamps operated by the latter, including interest, taxes, and insurance, is less than the amount that would be paid to a company, the difference is a saving to taxpayers which would not occur except with municipal ownership. If, therefore, new construction and payments on the principal of the debt as far as met out of taxes, do not exceed the amount of this saving, such disposition of the taxpayers' money is not an assessment upon them, or an investment made by them upon which interest should be received, because they have no alternative investment and could not have gained interest upon it anyhow, but it is an administrative economy tending to the ultimate extinction of the debt and further lessening of taxes. The city of Detroit paid $175,000 yearly for 1,279 private lights, and now gets 1,716 arc equivalents for $144,000 including interest and lost taxes. The difference of $30,000 yearly, if put into new construction or a sinking fund, is not an increased burden upon the taxpayers, and therefore does not give them a right to charge interest upon it to the consumers.

Municipal Ownership in Glasgow.

Municipal ownership is one of those phrases which, in a certain order of mind, take the place of reasoning, investigation, common sense. It is invested with a magic, a miracle-working, power which makes anything claimed for it credible. The city gas works in Philadelphia were long the substitute for argument in the mouths of advocates of municipal ownership. But their recent abandonment, after confessed losses and scandals, has led the champions of municipal operation of the public lighting and transit services to look more and more abroad for comfort, and Glasgow is the city whence they have derived most of it. So wild have been the romances set afloat about the immense profits derived by Glasgow from its control of public franchises, that the Lord Provost has been compelled to issue the following circular letter:

"The Lord Provost of Glasgow has received communications from all parts of America desiring confirmation of a statement to the effect that the citizens of Glasgow would be free from all taxes or rates in consequence of the profits derivable from their gas, water, electric lighting, and other undertakings of the government. I have accordingly been requested by the Lord Provost to inform you that this statement has no foundation in fact. There is no probability of this city being exempt from taxation.

"JOHN S. SAMUEL, City Chambers."

Thus is the socialistic millennium adjourned again. Taxes are not yet abolished, even by municipal ownership. Yet there is little doubt that if municipal ownership were given free course, it would ultimately make an end of taxes, for it would make an end of property to be taxed.—N. Y. Evening Post.

POWER TRANSMISSION

Electrical Installation in a Wilkesbarre Mine.

IN the mines of the Lehigh Valley Coal Company, four miles north of Wilkesbarre, Pa., an interesting electrical installation has been in operation during the past year. The main workings of the mines are under the Susquehanna River Flats eastward from the shaft toward that river from the Wyoming Hills—the Western outcrop of the anthracite coal belt. As the workings were greatly extended, the problem of handling the constantly increasing volume of water became daily more difficult and the haulage of coal by mules more expensive. A steam plant on the flats was impracticable on account of their

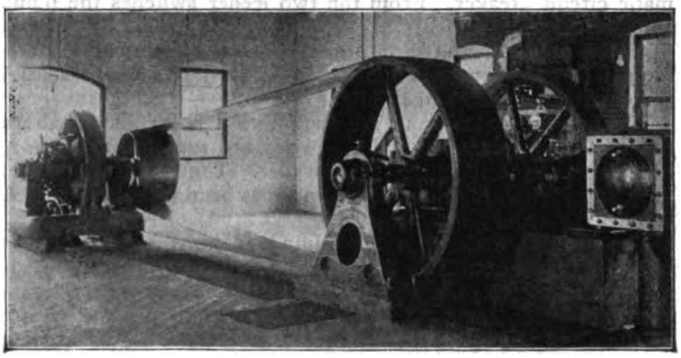


FIG. 1.—INTERIOR OF POWER HOUSE.

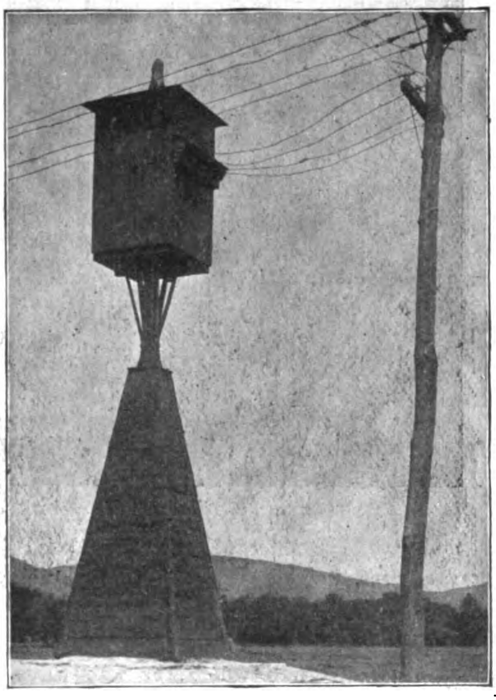

FIG. 2.—POINT OF SUSPENSION OF FEEDERS.

submersion and after careful investigation, the company decided to use electricity for the operation of the mine pump, and an electric cable hoist for the haulage of the coal over an extension of the main gangway.

The power house is placed near the head of the main hoisting shaft and contains the main hoisting engines, the generator and its driving engine. Steam is supplied from a battery of boilers set in another house about 200 feet away. The dynamo shown in Fig. 1 is a General Electric slow speed, 150-kilowatt direct current six-pole machine, driven by a Ball automatic tandem compound non-condensing engine. The speed of the engine is 200 revolutions per minute, that of the generator 400 revolutions per minute. The generator is compound wound for 500 volts at no load and 550 volts at full load. An oak switchboard is placed against the wall of the engine room and current passes from the generator to the switchboard through heavily insulated copper cables suspended on porcelain insulators in a conduit under the floor. The conduit is provided with a removable cover allowing ready access to the cables. The board is provided with two double pole feeder switches for the pump and hoist circuits in addition to the main double-pole station switch. The pump circuit is protected by fuses, the hoist circuit by an automatic circuit breaker. From the two feeder switches the pump and hoist circuits are carried to the pole line. The positive and negative sides of each circuit are connected to suitable lightning arresters to protect the instruments and generators from the destructive effects of lightning.

The pole line runs from the station to a point almost above the center of operations and the wires are run through a bore hole especially drilled for that purpose. The poles are 30 feet long and each carries one four pin cross arm with iron braces, wooden pins and glass insulators.

The positive feeders for the pump and hoist circuits consist of two separate 0000 B & S wires, and two 0000 B & S provide a common return. At about 5,000 feet from the power house two bore holes, each 350 feet deep are driven from the surface of the flats. One is provided with a six-inch iron pipe as a casing for the wires, the other with a 12-inch casing for the pump discharge. The six-inch pipe rises about 18 feet above the surface of the ground. The opening is thus protected against any great rise of water during freshets. A small cable house is supported on this pipe into which the line wires pass and make connection with the cable in the bore hole. The two positive feeders are connected to two separate cables, the two common return wires to one large negative cable. Each cable is heavily insulated with rubber and jute braid and then leaded and armored with iron wire protected from corrosive and electrolytic action by tarred jute. The cables are supported from the top of the stand pipe. The method of suspension of the cables shown in Fig. 2 is unique. Six cast-iron plates 1¼ inches thick and 18 inches square, are drilled with three 2-inch holes close together near the center of the plate. The six plates are placed one above the other on top of the stand pipe and the cables pass through the holes in all of the plates. The six plates are divided into three sets, each two in a set forming a clamp tightened by several small bolts. As one cable passes through the bottom clamping set the iron armored wires are spread out and tightly clamped between the two plates. Another passes through the hole in the first set and is clamped between the plates of the second set, the third armored cable being held between the third set. Each cable is, therefore, supported by its own armor and a separate clamp. Three additional lightning arresters protect the cable and line wires in the cable tower.

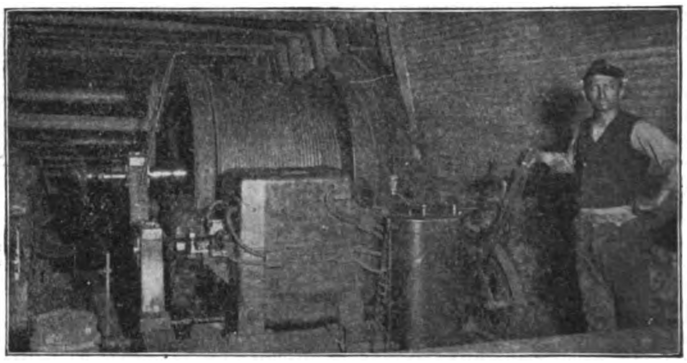

FIG. 4.—110 H. P. HOIST AT HEAD OF SLOPE.

At the bottom of the hole the cables are connected by single pole switches to the circuits operating the hoist and pump 600 feet distant. These underground wires are double rubber covered and are supported on glass insulators fastened to props along the ribs. A wooden switchboard carrying fuse boxes, main switch and starting rheostat for the pump is erected in the pump chamber.

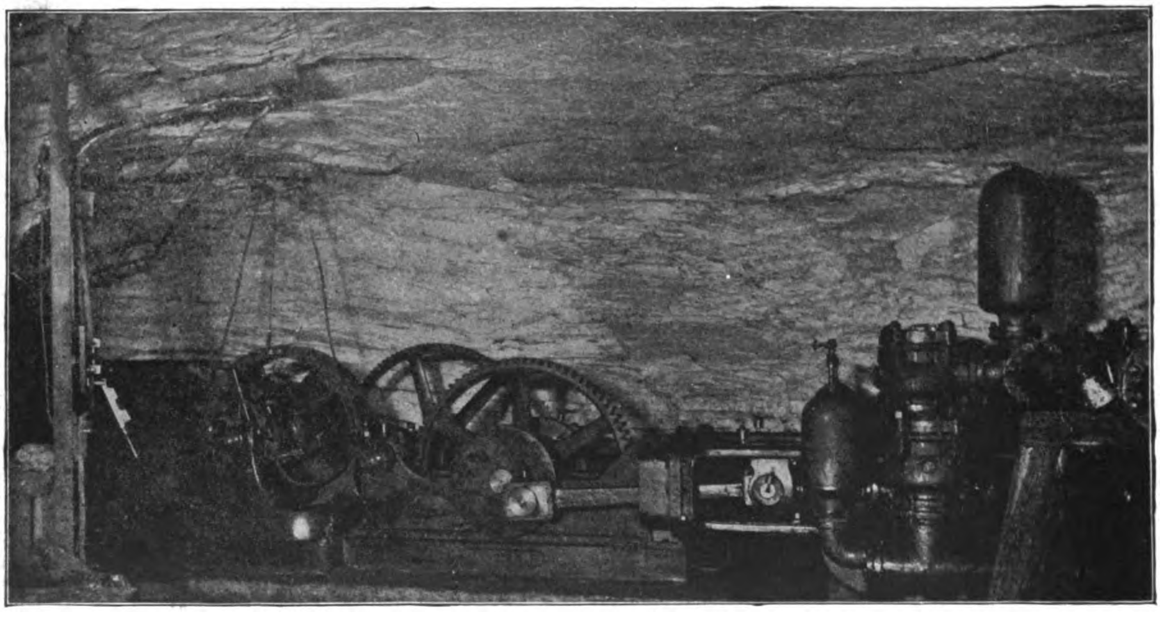

FIG. 3.—10 x 18 PUMP AND 85 H. P. MOTOR.

The motor for this pump, shown in Fig. 3, is mounted on a cast-iron bed plate and is geared by a double reduction gearing to the crank shaft operating the plungers. The motor is a General Electric shunt wound machine, with a capacity of 85 horse power continuously at a speed of 700 revolutions per minute. The pump is a duplex, double acting pot valve pump, manufactured by the Joansville Iron Works, with outside packed and connecting plungers, 10 inches in diameter by 18 inch stroke. The pump capacity at 25 revolutions is 600 gallons per minute, under a head of 360 feet. As with all pumps

operated with shunt wound motors the speed of the gearing is approximately constant—a great advantage where the pump receives little attention and where the pump capacity is limited. Should the pump happen to run on air, there would be no racing as in the case of air and steam pumps and the amount of energy consumed is only that required to overcome the mechanical friction of the rotating parts. The suction pipe drains from a large pump near the pump chamber and the water passes up through the 12-inch bore hole to the surface where a check valve prevents the water returning during any freshets when the pump is not in operation. A small 4 in. x 6 in. triplex plunger pump geared to a 5-horse-power multipolar slow-speed motor, pumps water up the small slope to the large electric pump.

The hoist shown in Fig. 4 is placed at the head of a small slope extending east from the parting at the foot of the main slope. The gangway in which the pump is placed is from 20 to 25 feet high and rather narrow. The hoist is placed on a platform built over the gangway and the operator stands on an auxiliary platform directly behind the hoist where he is not troubled by the vibration of the hoist when running. The motor is of the General Electric Railway type, completely closed to protect the windings from dust and moisture. It is series wound for 500 volts and is capable of developing 110 horse power for the intermittent work it is called upon to perform. The motor and drum are mounted on the same bed plate, and are connected by double reduction gears. The drum is of the friction cone clutch type, manufactured by the Lidgerwood Manufacturing Company, and is provided with two band brakes lined with wood. The clutch and brakes are operated by three levers and quadrants, while the motor is operated by a rheostatic controller to the left of the levers. The controller is provided with a magnetic blow-out. The hoist drum is 48 inches in diameter and 36 inches face and holds about 1,400 feet of one-inch wire rope. Under full load the rope strain on the hoist, at an average speed of 500 feet per minute is rated at 5,000 pounds. The hoist is operated under the single rope system, The empty trips are lowered by gravity and overhaul the rope, while the loaded trips are hauled up out of levels situated at intervals along the slope. The lowest level is about 1,200 feet from the hoist. The slope pitches on an average about 50 with a maximum of 80 at the approach to the knuckle, above which the empty and loaded trips pass on a parting directly under the hoist. The usual load up the slope is four loaded cars per trip at an average speed of 500 feet per minute. Each car weighs about three and a half tons, loaded, and in case of necessity the hoist is capable of hauling six cars per trip.

The installation of this plant was effected by the General Electric Company and since it was started it has operated continuously with satisfactory results.

NEWS AND NOTES

The Current Strength of a Lightning Flash.

To measure the current strength of a lightning flash seems almost impossible, yet it has been determined by noting the amount of permanent magnetism in certain rocks on the surface of the earth. The amount of magnetism in these rocks seemed out of proportion with the ordinary magnetism of the earth, so the proposition was advanced that it was caused by an electric current either passing through them or in the immediate neighborhood. Herr F. Pockels has recently made an investigation of sections of the basaltic rock of the Winterberg in Saxony, which show very irregular magnetism that must have been caused by a current of at least 2,900 amperes passing over the surface of the rock or else in the immediate neighborhood. Some basalt cut near a tree struck by lightning afforded him a better opportunity for estimating the strength of the current, which he has computed to be nearly 6,500 amperes.

MR. MARSDEN J. PERRY, of the Narragansett Electric Lighting Company, Providence, R. I., a well known banker, bought a rose souffle vase at the Dana ceramic sale for $5,000. He has one of the finest collections of porcelain in the country.

ELECTRIC TRANSPORTATION

Electricity on the Central London Underground.

IN our issue of June 30, 1897, we gave a general account of the Central London Underground Railway, the most important of all the undertakings of this nature in the world, with a map showing the route and the positions of the stations. Since that time extensions and alterations have been made, and we are in position to-day to present the following important data and illustrations which Mr. H. F. Parshall has furnished to "Engineering." The map accompanying this article shows the authorized lines of the Central London Railway, and indicates the routes of the city and South London and other electric and cable railways. The positions of the stations, and their distances apart, from centre to centre of the platform, are approximately as follows, starting from the western end of the line:

Shepherd's Bush to Holland Park, 1012 yards; Holland Park to Notting-hill Gate, 683 yards; Notting-hill Gate to Queen's-road, 768 yards; Queen's-road to Westbourne Park, 986 yards; Westbourne Park to Marble Arch, 1,288 yards; Marble Arch to Davies street, 642 yards; Davies street to Oxford-Circus, 699 yards; Oxford-Circus to Tottenham-court Road, 666 yards; Tottenham-court Road to British Museum, 682 yards; British Museum to Chancery-lane, 746 yards; Chancery-lane to Post Office, 1,163 yards; Post Office to Bank, 828 yards. This gives a total of 10,163 yards.

This railway is of especial interest to Americans as the entire

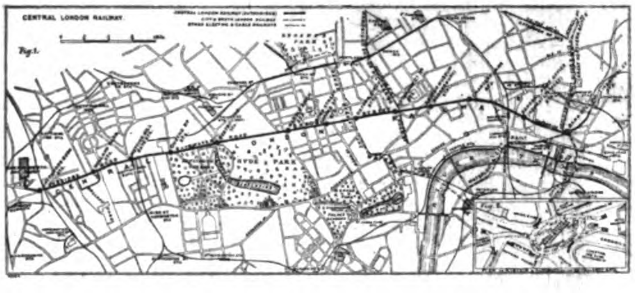

FIG. 1.—MAP SHOWING ROUTES OF THE CENTRAL LONDON AND OTHER RAILWAYS.

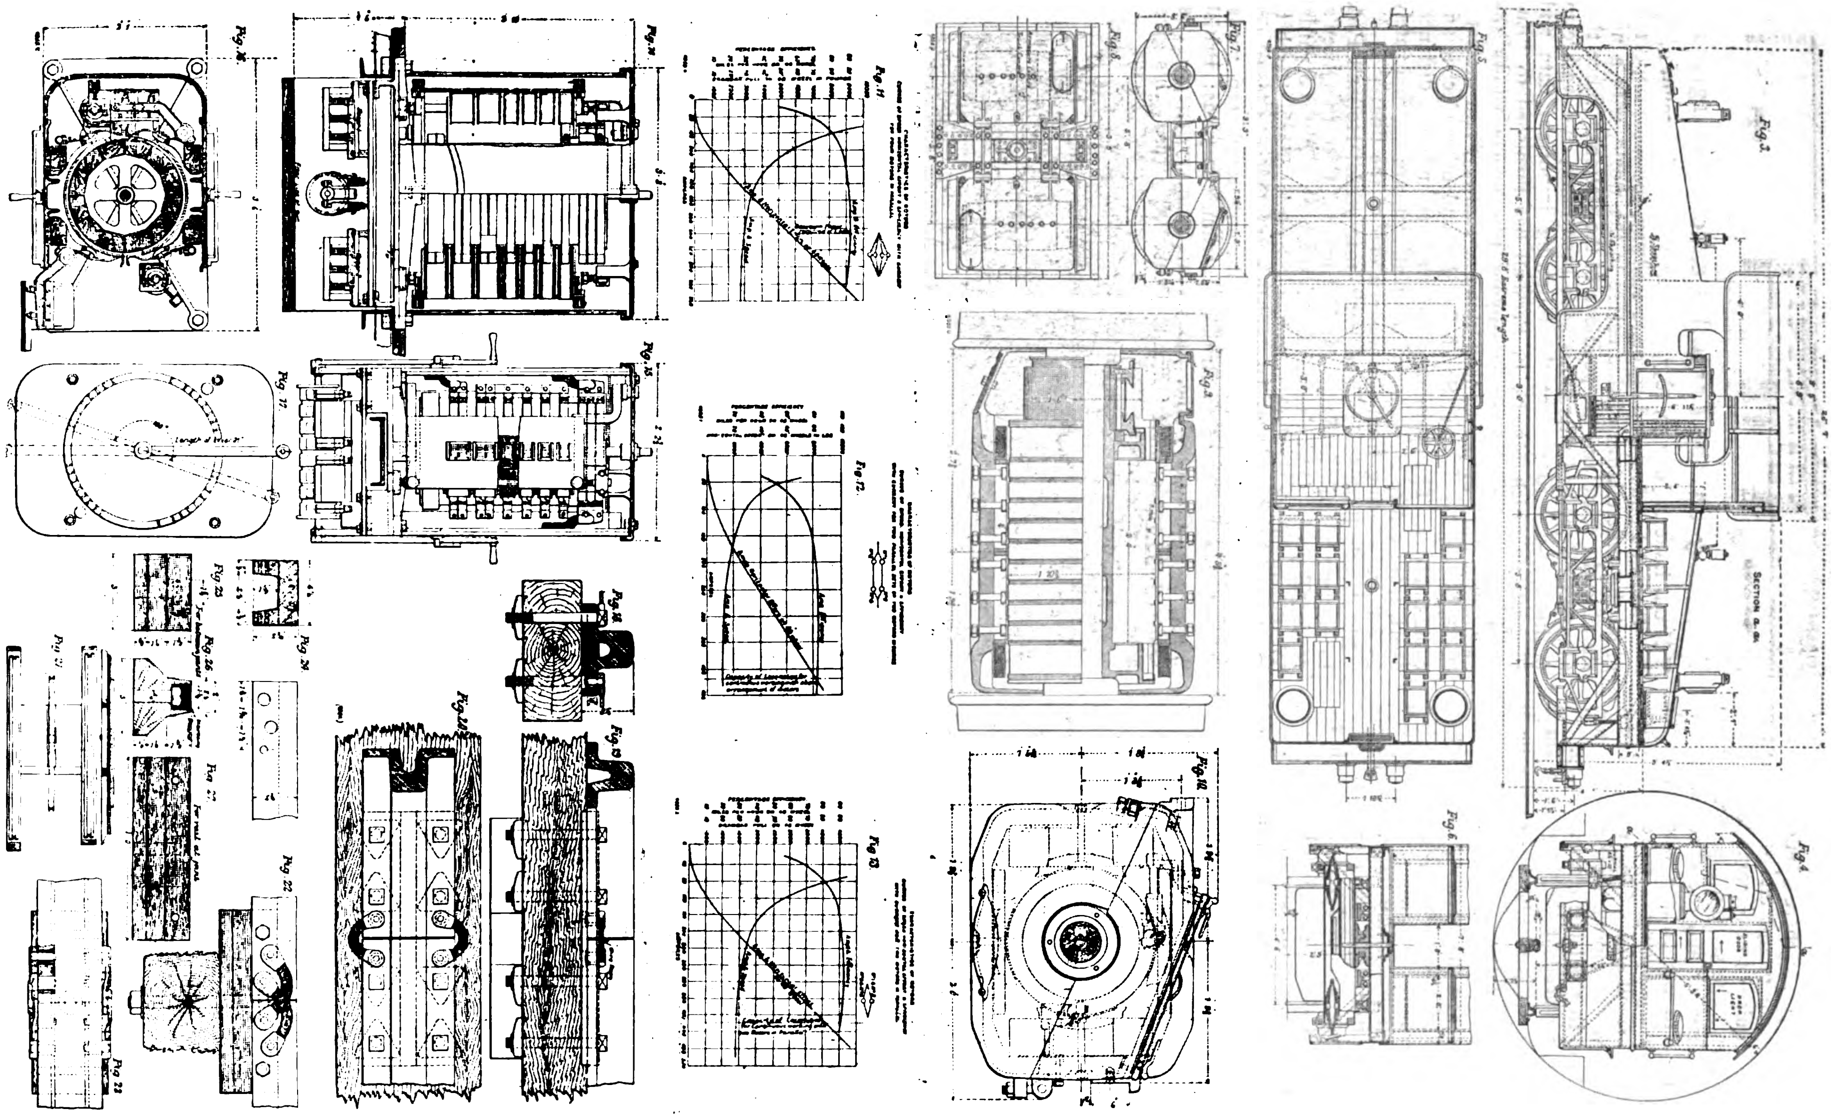
electrical equipment has been designed and manufactured in the United States. With the exception of the elevators, of the famous Sprague make, the entire electrical contract has been assumed by the British Thomson-Houston Company, Limited, representing in Great Britain the General Electric Company, of Schenectady.

The locomotives built by the General Electric Company are shown in Figs. 3 to 6, and the dimensions are given in the following table:

The wheel centres of the truck are	5 feet 8 inches and 6 feet
Distance from centre to centre of trucks	14 feet
Number of driving wheels	8
Total number of wheels	8
Diameter of wheels	3 feet 6 inches
Total wheel-base	20 feet 9 inches
Total length of locomotive	29 feet 8 inches
Total height	9 feet 8½ inches
Weight on each wheel	about 5½ tons
Total weight of locomotive	about 48 tons
Drawbar pull	14,000 pounds (6.2 tons)
Drawbar pull running at 22 miles per hour	8,000 lb (3.5 tons)

The weight of each locomotive will be about 45 tons. There will be four gearless motors on each, that is, one on each axle. The weight of the frame and coils of each motor, with field coils in place, will be 8,500 pounds, while the weight of the armature, complete with sleeve and conductor, will be 3,000 pounds, making a total weight for the motor of 11,500 pounds. The driver's cab is fixed in the centre of the locomotive (Fig. 3), giving him a capital look-out both ahead and astern. In the space over the trucks are fixed resistance coils (Figs. 5 and 6)



FIGS. 3 to 27 Incl.—DETAILS OF LOCOMOTIVE, MOTORS, CONTROLLERS AND TRACK CONSTRUCTION, CENTRAL LONDON RAILWAY.

with a passage way between them, the whole being inclosed by a sheet-iron cover.

The trucks and motors are illustrated in Figs. 7 to 10. The hollow axis of the armature is shipped directly on to the axle, and occupies the whole of the space between the wheels. The whole motor, which has an armature 1 foot 10½ inches in diameter and four field coils, is inclosed in an iron case, access to the interior of which is obtained through a door (Fig. 10). The efficiency of these motors is between 92 and 93 per cent. The temperature will not rise more than 90 degrees Fahrenheit on a two hours' run at full load. The performance of the motors with the 48-inch wheels originally proposed, is shown in Figs. 11, 12, and 13. The size of the wheels has since been reduced to 42 inches, and the power of the motor otherwise augmented considerably, in order that a high average speed may be attained.

Figs. 14 to 17 show the series parallel controller. At starting, the four motors are placed in parallel in pairs, and the two pairs in series. At the same time there is a resistance in series with each motor. Then one pair of motors is progressively short-circuited, and finally all four are placed in parallel. There are,

in all, twenty-two stages in the regulation. Each section of the line comprises two inclines of 1 in 33, joined by a length on the flat, so that the train is greatly accelerated by gravity at starting, and retarded as it approaches a station. It is only by the combination of these circumstances, and by the aid of the powerful motors, that the rapid services promised could be attained.

Figs. 21 to 27 show the third rail by which the current is conveyed to the locomotive. The return current passes through the ordinary rails (Figs. 18 to 20). The third rail is of steel weighing 80 pounds to the yard, and is a channel section. It is supported on creosoted wood insulators, and the joints are bonded with short flexible crown bonds. The track rails are of bridge section, weighing 100 pounds to the yard, and laid on horizontal sleepers. Each joint has two bonds.

It might be of interest to give a few figures of the estimated passenger capacity of the line. It is said that with 2½-minute trains, and all seats occupied, each person traveling the whole distance, about 85 million passengers could be carried in the year; but as everyone, naturally, would not go the whole distance, it has been estimated that 100 million persons would be carried in twelve months; or, rather, that that number of passenger journeys could be made in the time. That may appear a very optimistic view to take of the prospects of the railway. On most suburban lines there is a rush-in in the morning and a rush-out in the evening, at both of which periods seats are at a premium; in the third-class carriages they have sometimes to be shared by double the orthodox number of persons. For the rest of the day, however, traffic is apt to languish and one person to a compartment is not an unusual average, but in the streets on the central railway route there is traffic all day. Omnibuses and cabs are always going and the former if not always full are generally tenanted. The Central London Railway in virtue of its lifts and its continuous service of 2½ minutes will be in many respects as convenient as an omnibus and far more rapid. The stations are so close together that passengers can hardly be landed at a great distance from their destination supposing it to be on the line of route. Mr. Forbes, of the London, Chatham and Dover lines, estimated that there would be $8,000 per mile per week for the local traffic on the Midland Railway. In 1866, Mr. Baker (now Sir Benjamin) gave $4,030 to $5,395 per mile per week as the percentage on the Metropolitan Railway between Paddington and Farringdon street. Between 1867 and 1890, however, the London population has increased 35 per cent., but the number of passengers in public conveyances has grown in much greater proportion, that is from 64,000,000 to 459,000,000. That is to say the ratio of travel has increased twenty times as fast as the growth of population, taking the number of journeys only, irrespective of their length.

The engineers to the Central London Railway are Sir John Fowler, Sir Benjamin Baker, and Mr. Basil Mott (who succeeded Mr. Greathead); Mr. Henry Tennant, late general manager of the North-Eastern Railway, is chairman, and Mr. R. O. Graham, also an old North-Eastern Railwayman, is the secretary. The Electric Traction Company, of which Sir R. Farrant is chairman, has undertaken to construct and equip the line for a lump sum of a little over 15 million dollars, and contracts for the construction have been let to Messrs. Walter Scott & Company, Messrs. John Price & Company, and Mr. John Talbot.

Electricity on Board the "Niagara".

THE Niagara, lately launched at Wilmington, Del., and belonging to Howard Gould, is the largest steam yacht ever built in the United States, and in point of tonnage is only equalled by three or four yachts in the world. Her displacement is about 1,900 tons. She is 272 feet long, 36 feet beam, depth to spar deck 27 feet, draught 16 feet. She is bark rigged, has three decks, a double bottom and twin screws. The yacht, which was built by the Harlan & Hollingsworth Company, is luxuriantly furnished and all comforts are amply provided for. The electric plant of the Niagara will be as complete as has ever been installed on board a ship. It will consist of two dynamos, each capable of furnishing 400 sixteen-candle power lamps, and a storage battery with a capacity of eighty lamps. When desired the dynamos can be made to operate 900 display lights at night, also a powerful searchlight on the bridge. Electricity will be employed in every conceivable way on board the Niagara. There will be electric heaters, curling tongs, smoothing irons, ranges, warming pans and lifts. Electricity will operate the laundry and drying rooms; it will heat chafing dishes and bring out the music of the big orchestrion. The ship will be electrically and steam heated throughout with radiators, coils and pipes in the usual manner.

Sprague Multiple Unit Control and the Adoption of Electricity on the Brooklyn Elevated System.

THE recent news of the adoption of electricity on the system of the Brooklyn Elevated Railroad Company came very much in the nature of a surprise to the public. Attention had been so intently fixed on the Manhattan Elevated, and rumor was so rife with what its managers proposed or did not propose to do, that most people lost sight of the problem and conditions confronting a like road across the Bridge, but also within the borders of Greater New York. Hence, the statement that the Brooklyn concern had done business while the New York road had merely been talking against time, was a startling event, and even now there is much conjecture as to how it all happened. We are glad to be able to give herewith what we understand to be the correct data as to the incidents leading up to the adoption of electricity, at a time when the determination in its favor means very much. It will be seen that credit is due Mr. Frank J. Sprague and the gentlemen associated with him, for this momentous decision.

For about three months, pending the hue and cry on the Manhattan, and realizing that the competitive conditions on the Brooklyn Bridge would require some initial electrical equipment on the Brooklyn road, Mr. Sprague and his friends had been quietly doing effective work. As long ago as May, Mr. George Cornell, chief engineer of the road, stated in a communication to one of the manufacturing companies that he must be able to run individual cars, but despite this fact, it is stated, the companies, other than the Sprague Company, proposed locomotive systems, some with visionary schedules, and another actual schedule determined by test at Schenectady, all requiring the locomotive application, with the suggestion on the part of Mr. Martin, the electrical engineer of the Bridge, of using two locomotives in a train.

Mr. Cornell meanwhile went to Schenectady, and saw the initial trials of the Sprague multiple unit control in August, and publicly stated that that was the only system which would be accepted on the road.

Later, Mr. John Lundie, of Chicago, who made the report for the Illinois Central, was requested to come to New York by Mr. Sprague to make a very thorough investigation of the Brooklyn Elevated Railroad and its problems in all its details. He was put in close touch with Mr. Cornell, and a most elaborate series of investigations was made extending over a number of weeks involving all of the questions of cost of equipment and operation under various schedules and varying accelerations. The results when presented to Mr. Cornell and indorsed by propositions by the Sprague Company, presented through Mr. Shepard and Mr. Sprague, were of such a convincing character that Mr. Cornell absolutely decided on the use of the multiple unit control and specifications were issued calling separately for motors and controls. These were the papers which were stolen from Mr. Sprague's desk recently, and for which a reward of $1,000 is offered.

The Walker Company was the lowest bidder, and received the order for the motors. The Sprague Company bid on the controls, and the motors have to be built to meet their requirements. The whole question of the equipment and the important fact is the abolition of the locomotive and the adoption of the individualized cars with the Sprague multiple unit control.

There has been, it is now stated, no general contract for the road signed, but simply an order placed for 48 motors mounted on trucks, and from there on the equipment is absolutely a Sprague equipment, put in under Sprague advice and under Sprague responsibility to meet the requirements determined upon.

The cars are arranged so that they can be run on a 16½ or 18-mile schedule, depending upon whether two or four motors are used. The very remarkable fact was brought out by Mr. Lundie, considering a given car mileage where high schedules are required, that whatever the schedule required, the total cost of an equipment, including the central station, transmission, storage battery equalizers, trucks, motors and controls, as well as cost of operation, was entirely in favor of the multiple unit

system. In fact, as Mr. Lundie stated, "every reason, commercial, practical and economical, was in favor of the multiple unit system."

Of course, such schedule speeds as are possible with this system, limiting the weights of cars without loads to perhaps 21 to 23 tons, are absolutely impossible to a locomotive system because with the two motor equipment, from 59 to 63 per cent. of the weight of the train is on the drivers, and with the four motor equipment, the entire weight of the train.

With regard to the future of the Brooklyn Elevated, it is probable that the Fifth avenue will be the first one equipped and the multiple unit system will be used, but the make of motor is not yet determined. With the individualized system, high schedule speeds are possible on existing structures; that is, the highest schedule that it is possible to maintain with existing station intervals and grades.

The statement made in various papers some time ago that double an 18-mile schedule could be maintained on an underground railroad, is "simply rot," Mr. Sprague says. Eighteen to nineteen miles is the maximum possible using every wheel in a train where the station stops are only a third of a mile apart. Higher speeds are only possible where the stops are at less frequent intervals, no matter whether overhead or underground.

Asked his views as to the Manhattan situation, Mr. Sprague says, very frankly: "With regard to the Manhattan road, we have had recently no conference whatever with the Manhattan people. They have not so far as I am aware, made any practical investigation of the multiple unit system. All proposals which have been made to them by other companies have been on the locomotive idea, and so far as I can judge, have been attended by a good many misstatements of fact. I hope, as every other engineer should hope, that when the Manhattan people have come to final conclusions in their negotiations with the Rapid Transit Commission about extensions, that they will then invite a comprehensive bid covering every detail of equipment, and if that is done we shall be perfectly prepared to submit such plans to them as cannot but command serious attention.

"I am perfectly certain that the multiple unit system if anything is of more vital importance on the Manhattan road than anything else, not only because of its size and extent, but because of the limitations of strains on the structure, and the tremendous competition that the Metropolitan and Third Avenue roads will afford when projected equipments are put in operation will demand the highest possible schedule speed on the elevated railroad. There is only one way to get it, and that is to make use of the weight of the train on the drivers.

"Other important roads are going to adopt this system, but of these I cannot speak at present. We do not control all methods of operating cars electrically. That is a foolish statement, by whomsoever made, but we do control, and have reduced to practice the only effective method of handling a number of individually equipped cars by what is called the multiple control system."

Caution, Liquidation and Firmness.

With the possibility of war with Spain hanging over their heads, it would indeed be strange if American investors did not husband their resources and speculators take in sail. This country does not want to fight, but if it has to, it will, and it will vote and raise ten times $50,000,000 for the purpose. In the meantime it is hoping and praying for honorable peace, and working just as hard as though no war scare was in the air. There is continued briskness in trade, and almost every line reports an excellent demand. Orders are very large for wheat, flour, pig iron and copper. The advance in copper appears to be thoroughly justified.

During the week, 29,538 shares of Western Union were sold between 85 and 84¼. Of General Electric there were 13,223 shares sold, from 31 down to 30. In Boston, 869 shares of American Bell Telephone exchanged hands at from 262 down to 249½. In Canada, Commercial Cable dropped 8 points to 177, and the price is now 11½ points below the highest of this year. New York Edison is steady at 130.

Copper is 11.87½ cents, and it is safe to say no lower price is looked for. Heavy steel rail, Eastern mill, is a trifle weaker, at $17.50. A copper sale to home consumers of 4,000,000 pounds is rumored.

Amateur Model-Making Competition at the Electrical Exhibition.

A committee consisting of Prof. Morris Loeb, Dr. C. A. Doremus, Dr. W. E. Geyer and Mr. T. C. Martin has drawn up rules and regulations for an amateur model making competition in connection with the Electrical Exhibition. Printed forms can be had from the management, 15 Cortlandt street. The classes are given below, each class having prizes not to exceed $50.00 and bronze medals, the exhibits to be judged by a committee of five well-known men. It is believed that the contest will awaken general interest and elicit some beautiful and interesting apparatus. There are a great many young people and students in and around New York who find pleasure in handiwork of this character. The classes are as follows, and the exhibits must be entered a week before the exhibition begins:

CLASS A.—Working model or actual machine of a dynamo-electric or electro-dynamic type: made by one or more boys under 21, so far as designing, lathe work, assembling and finishing is concerned.

CLASS B.—Instrument of precision, made by amateur or student; including galvanometers, resistance bridges, etc., etc.

CLASS C.—Practical application of electricity to communication, the assembling and finishing to have been the work of a single exhibitor.

CLASS D.—Ingenious application of electrical appliances to domestic, etc., uses by an amateur under 18; none of the apparatus to be necessarily of home manufacture.

CLASS E.—Design or working drawing of an electrical appliance, or installation, made within the past twelve months by a student of a recognized chartered institution, and bearing the instructor's certificate as to its bona fides.

CLASS F.—Design or instrument made by a teacher, below the grade of College Professor, for illustrating some electrical law.

Commercial Cable Co.,

The annual meeting of the Commercial Cable Company was held last week. The revenue from the operations of the cables, after deducting all expenses, amounted to $1,200,155, an increase of $76,502 over the previous year. The net revenue from the land lines, Postal Telegraph, was $645,185. The net revenue from the combined systems was $1,845,340.

Out of this have been met the interest on the first mortgage bonds and debenture stock, dividends of 7 per cent. on the stock, and bonus of 1 per cent. on the capital stock—a total of $1,440,000—leaving the balance of net revenue for the year $405,341.12. The further sum of $250,000 will be set aside and invested in high-class securities, as an addition to the reserve fund, which will then stand at $2,608,329. There have been added to the land line system during the year 933 miles of new pole line and 3,966 miles of wire.

The directors elected for the ensuing year were John W. Mackay, James Gordon Bennett, Gardiner G. Howland, Col.

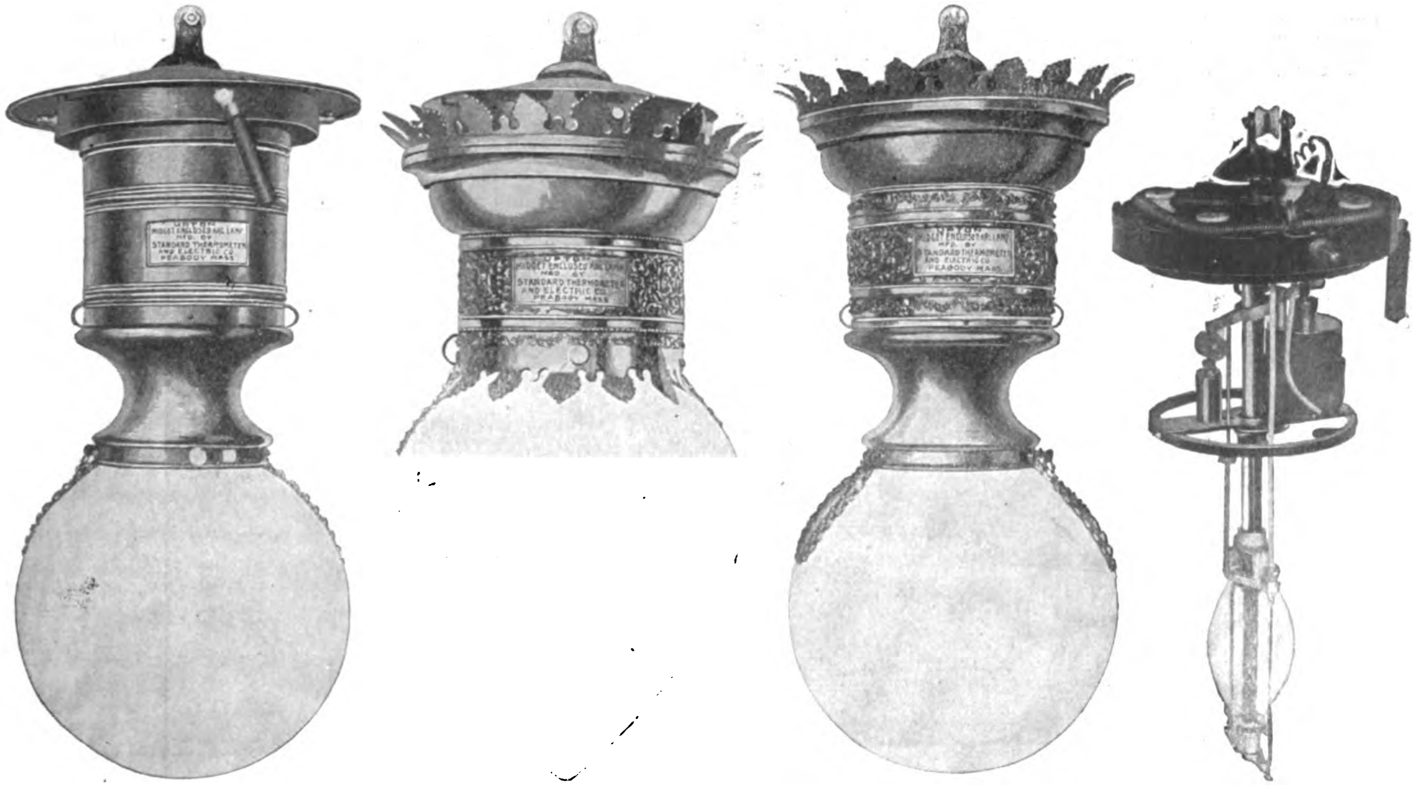
William Jay, George G. Ward, Sir William C. Van Horne, E. C. Platt, the Right Hon. Lord Strathcona and Mount Royal, Charles R. Hosmer, Thomas Skinner, Clarence H. Mackay, Albert B. Chandler and Dumont Clarke.

At the meeting of the directors which followed, the following officers were named: President, J. W. Mackay; vice-president and general manager, G. G. Ward; vice-presidents, C. R. Hosmer, A. B. Chandler and C. H. Mackay; treasurer, E. C. Platt; secretary, Albert Beck; assistant secretary, J. O. Stevens.

TRADE NOTES & NOVELTIES

Covers and Canopy Switch for "Standard" Enclosed Arcs.

THE accompanying cuts illustrate some of the different styles of covers which the Standard Thermometer and Electric Co., of Peabody, Mass., are using on their enclosed arc lamps. These lamps are designed for both indoor and outdoor service, the outdoor lamps being weatherproof and requiring no hood. They burn singly on 110 volt circuits and are provided with a device to adjust the arc for any voltage of line between 100 and 125. A very simple arrangement is also provided with the lamp enabling the user to adjust the lamp to take any number of amperes from three to six as may be desired without change of magnets. It will also be noticed that each lamp is provided with a switch placed in the canopy. If desired, however, these switches can be omitted in cases where the lamps are to be operated from wall switches. The covers of these lamps are finished in any style that may be required. The manufacturers of the Upton Midget Lamp claim that their lamp is the simplest on the market, having the fewest moving parts. A new catalogue has just been issued showing their enclosed arc lamps for all circuits which can be obtained from the main office or any of their agents.



STYLES OF COVER AND CANOPY SWITCH, "STANDARD" ENCLOSED ARC LAMPS.

MR. E. G. BERNARD, of Troy, was in New York City last week on important business.

Ferracute Machine Co.

The Ferracute Machine Company, of Bridgeton, N. J., manufacturers of presses and dies, have been very successful in their business during the last two years, and have kept a full force of workmen running through the dull times. Their foreign trade is increasing and they are constantly shipping machines to England, France and Germany. They have recently sent presses for notching armature discs to France, and also shipped a large double crank press to Budapest. This is the second large machine they have sent to the same factory, and they have supplied a number of the same style to the American factories. They make 120 different styles of double crank presses, with various forms of beds, and also a line of presses for light metal, which are used for cutting smaller discs. The company have recently issued circulars illustrating these machines, and will shortly issue a larger and more expensive catalogue than anything they have sent out heretofore.

Demand for the Willard Storage Battery.

Sipe & Sigler, manufacturers of the Willard storage battery, have been awarded the contract for 900 Willard cells for the city of Chicago, to be used in connection with their various fire alarm circuits. This contract was awarded after a competitive test with all prominent makes of storage batteries. They have delivered 58 cells to the Washburn Memorial Orphan Asylum, Minneapolis, Minn.; 64 cells to the Eclipse Electrical Co., St. Louis, Mo.; 80 cells to the American Incandescent Lamp Co., Warren, Ohio; 50 cells to M. A. Seed, St. Louis, Mo.; 28 cells to Prof. C. H. Wing, Ledger, N. C.; and 38 cells to the Riker Electric Motor Co., Brooklyn, N. Y. These batteries are to be used in connection with isolated plants.

For telegraph and telephone purposes, 100 cells have been sold to the Home Telephone Co., Cleveland, O.; 40 cells to the American District Telegraph Co., Cleveland, O., and several small orders to the Western Union Telegraph Co.

The horseless carriage trade is very brisk, and they have received within the past two weeks orders for 700 horseless carriage cells, among the purchasers being the Riker Electric Motor Co., Brooklyn, N. Y.; The United States Carriage Co., Chicago, Ill.; The C. H. Barrows Co., New York; Montgomery, Ward & Co., Chicago, Ill.; and the Gugler Electric Co., Minneapolis, Minn.

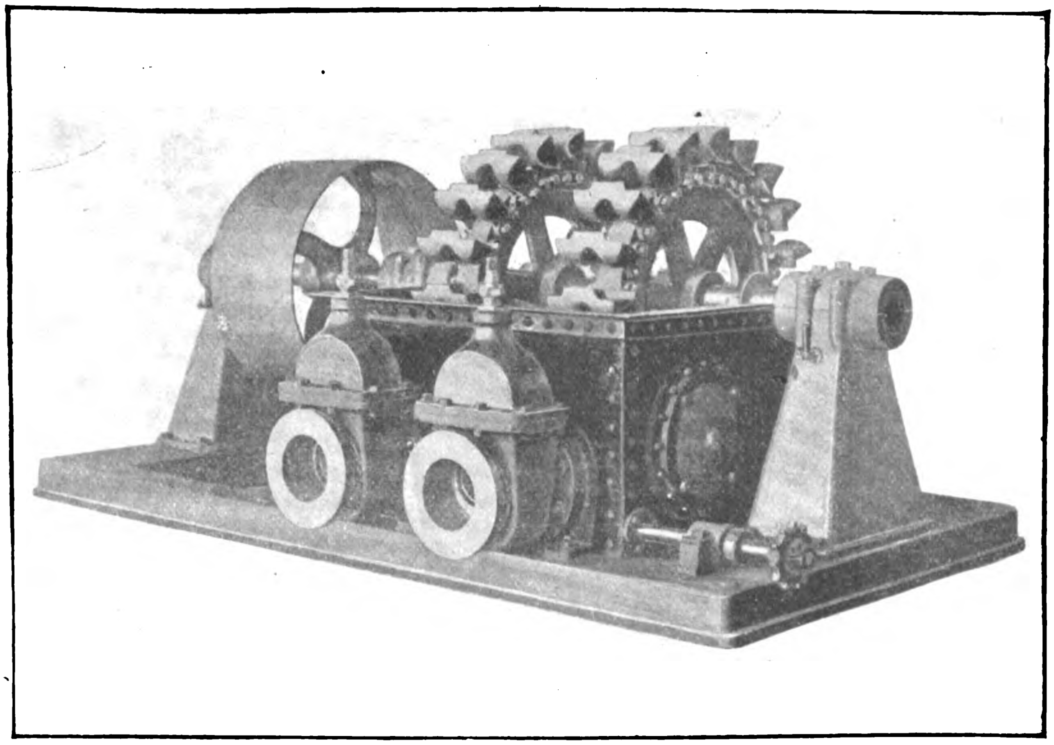
American Impulse Water Wheel in France.

A STRIKING example of the utilization of water power made possible by wheels of the impulse type, is presented in the arrangements recently made for power in the textile goods factory of M. Benoist Cadet Fils, at La Bastide, a town south of Bordeaux, in the Department of Tarn, France. Here a steam engine which formerly was used to furnish the power for the entire factory is now held in reserve for periods of low water, and the greater part of the time power is furnished by a 36-inch twin impulse wheel, working under a head of 128 feet at 285 revolutions per minute, and developing 40 horse power. The use of contracting nozzles makes a high efficiency possible with the varying loads. The accompanying illustration shows the wheel sent to La Bastide, by Messrs. Powell and Colné, export agents, Bowling Green Building, New York. It was furnished them by the American Impulse Wheel Company, 120 Liberty street, New York. The photograph was taken with the top casing removed and the shape of the buckets peculiar to this wheel can be observed. The design has been carefully worked out, and in this wheel as in all others made by the American Impulse Wheel Company, the mechanical perfection attained is of the highest.

The high efficiency of the wheels made by this company is due to the close attention and study which its engineers have given to every detail and to the great care exercised in manufacturing. A prime mover with so low a first cost, and almost negligible expense for repair and requiring little or no attention while running, is an attractive one to large numbers of manufacturers who are at present burdened with heavy expenses in connection with their motive power.

The possibilities of the electrical transmission of energy are now so great that many concerns might at comparatively small expense utilize water powers even though they be located at considerable distance from their establishments.

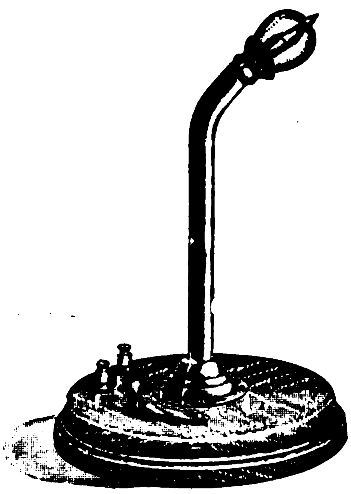
The numerous inquiries on such subjects which the American Impulse Wheel Company receive, have the careful consideration of their engineers, and as full information is sent in reply as the data presented will permit.



AMERICAN IMPULSE WATER WHEEL, AT LA BASTIDE, FRANCE.

AMERICAN RHEOSTAT COMPANY, of Milwaukee, Wis., reports that it is doing a very large business, and has recently shipped some noteworthy orders of rheostats to England, Belgium and Japan. It is also enjoying a large demand for Perfection starters from among the electrical contractors.

Mianus Battery Lamps for Sleeping Rooms.



A very handsome battery lamp has just been brought out by the Mianus Electric Company, Mianus, Conn. The claims in favor of an electric night lamp over an oil lamp which is smoky, emits carbonic acid and consumes the oxygen of the air, are undisputed. This electric lamp, which can be placed near the clock on a table, has a switch attached to its base and can therefore be lighted and extinguished at will. Dry batteries are used for the lamp, which will last a year without attention. The price of the outfit with a 4 c. p. lamp, without battery, is $1.50; with 4 cells of battery in a varnished hinged lid box, $2.50; and with 6 cells, $2.85. This box has binding posts so that wires can be run from posts on the lamp to posts on the box. The lamp may be used as a hall light or in any place where an occasional light is required.

Storage Batteries for Chicago Fire-alarm Service.

In accordance with his scheme to replace about 5,000 gravity cells with storage batteries to furnish current for the fire and police telegraph circuits of the city of Chicago, City Electrician Ellicott received bids on February 26 for 900 cells of secondary battery of 10 ampere hour capacity and 300 cells of 150 ampere hour capacity. The Police Telephone and Signal Company, of Chicago, offered to supply the chloride accumulators of the Electric Storage Battery Company of America for the whole outfit for $4,350; the American Battery Company, of Chicago, tendered the installation complete for $4,500, and Sipe & Sigler, of Cleveland, put in a bid of $1.20 each for the 900 smaller cells. All bids were furnished with the guarantee that the yearly cost of maintenance for the batteries should not exceed 7½ per cent. of the first cost. It is estimated that by replacing the existing primary batteries with storage cells, the city will save at least

$5,000 a year by reducing the expense of keeping up the plant.

The contract for the larger batteries was awarded to the American Battery Company for $3,150 and for the smaller cells to Sipe & Sigler for $1,080, making the total cost $4,230.

The Schlicht Combustion System.

The Schlicht system of combustion as applied to steam boilers, described in another column ought to be attentively studied by all central station men. Mr. P. J. Schlicht, its inventor, has hit upon a most novel plan of increasing coal economy and its simplicity is not its least factor of merit. The Schlicht Heat, Light and Power Company, of 27 William street, New York, have dozens of letters of testimonial as to the efficacy of their system.

"Not the Same."

The Warren Specialty and Electric Company, of Warren, O., write us: "It seems that some company who has a name similar to ours has been unfortunate enough to pass into the hands of a receiver. We, of course, sympathize with our namesake, but desire to inform the trade that while we have troubles, this is not one of them, and that we are still selling anti-trust lamps in large quantities."

A Few Striking Facts About Chloride Accumulators.

A circular has just been issued by the Electric Storage Battery Company as to the use of chloride cells, and we cull a few items:

35,000 h. p. hours are stored daily in chloride accumulators.

It is a significant fact that four of the central stations equipped with chloride accumulators have contracted for duplicate plants.

The largest single batteries in the world consist of 130 chloride accumulators of 9,600 ampere hours capacity operated in the service of the Hartford Electric Light Co., and 160 chloride accumulators of 7,600 ampere hour capacity in the station of the Philadelphia Edison Company.

19,000 chloride accumulators are in operation in telegraph, fire alarm and signal services.

Prices Paid for Electric Lighting.

The Fort Wayne Electric Corporation has rendered a public service by issuing a pamphlet, with the above title, giving full details for each place, inclusive of population, nature of power, cost of fuel, etc., schedule, candle power and number of lamps. It is a remarkably handy and useful little book.

ADVERTISERS' HINTS

THE K. & W. COMPANY, Pittsfield, Mass., manufacturers of the K. & W. commutator brush find that it is proving very popular, as in many places where trouble has been had with commutators the brush has overcome the difficulties most satisfactorily.

THE NATIONAL CONDUIT AND CABLE COMPANY, Times Building, New York, submit another letter attesting the excellence of their cables and cement lined ducts.

THE WORTHINGTON COMPANY, New York, say that it was only a few years ago that the Worthington Duplex pump patent became public property and many of the minor details of construction are still covered by patents belonging to them.

EUGENE MUNSELL & CO., 218 Water street, New York, advertise "Empire" insulated cloths and papers and "M-I-C" compound for armature coils and fields.

WM. E. KLINE & CO., 121 Liberty street, New York, have opened a Chicago office with Mr. W. R. Garton in charge at 414 Ashland Block, for the sale of their miniature and standard incandescent lamp, bicycle lamps and general lighting supplies.

THE CREFELD ELECTRICAL WORKS, 49 Federal street, Boston, Mass., have removed their New York office from 136 Liberty street, to 15 Cortlandt street.

GENERAL INCANDESCENT ARC LIGHT COMPANY, 7 Broadway, New York, advertise the new Bergmann alternating enclosed arc lamp for any frequency and with the same method of trim as the standard "D. C." lamps.

J. JONES & SON, 67 Cortlandt street, New York, advertise their automatic time cut-out for turning out window lights and similar uses.

C. F. SPLITDORF, 25 Vandewater street, New York, is well prepared to supply at short notice X-ray coils, telephone coils, bobbins and electro-magnets.

A. D. FRENCH, 44 Broad street, New York, furnishes octagonal poles, ties, cross-arms, conduit, etc. Prices may be obtained on application.

THE AUTOMATIC SWITCH COMPANY, Baltimore, Md., advertise solenoid, non-reversible, non-magnetic motor starters of which their catalogue contains a full description.

THE STANDARD THERMOMETER AND ELECTRIC COMPANY, Peabody, Mass., call attention to the Upton "Midget" enclosed arc lamp for constant potential circuits at 100 volts. This is but one of their many styles.

WE HARNESS THE LIGHT, say the Wheeler Reflector Co., Boston, Mass. This is by means of their different reflectors for various and special purposes.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, Pittsburg, Pa., point out the noteworthy features of their direct current multipolar generators and motors.

THE GOLD STREET CAR HEATING COMPANY, Frankfort and Cliff streets, New York, illustrate a coil as used in the construction of their standard heaters.

THE ELECTRICAL BROKERAGE COMPANY, Elkhart, Ind., submit a list of bargains in dynamos, arc lamp clutches, pulleys, etc., etc.

THE CENTRAL TELEPHONE AND ELECTRIC CO., 1123 Pine street, St. Louis, Mo., advertise up-to-date telephones and switchboards with prices to suit the times.

THE FULLER COMPANY, Detroit, Mich., are building the mechanical draft fans for the Ypsilanti and Ann Arbor Railroad.

THE RIDGEWAY DYNAMO AND ENGINE CO., Ridgeway, Pa., claim to manufacture the only dynamo in the world which is provided with special coils for balancing armature reaction and securing perfect commutation with absolutely fixed brushes.

THE CRANE COMPANY, Chicago, have equipped over twenty large power houses during the past year with high-pressure gate valves, pipe and fittings.

THE WESTERN ELECTRIC CO., Chicago and New York, advertise no less than thirty varieties of batteries, wet and dry, also carbons, coppers, solutions, and all battery accessories.

THE CENTRAL ELECTRIC CO., Chicago, Ill., carry everything in the line of supplies and will handle orders both wholesale and retail.

K. McLENNAN & CO., 1128 Marquette Building, Chicago, Ill., on receipt of a coupon which may be clipped from their "ad," will send free a sample stick of Gale's commutator compound.

THE 1898 LUNDELL fan motors are now ready and include new styles and new prices which may be obtained by writing the Sprague Electric Co., 20 Broad street, New York.

MIANUS ELECTRIC CO., Mianus, Conn., say that both their telephones and prices talk, and we may add both make themselves heard.

LOMBARD WATER-WHEEL GOVERNOR CO., 61 Hampshire street, Boston, Mass., have installed over 70,000 horse power of their governors which are now in use.

B. F. STURTEVANT CO., Boston, Mass., build direct connected generating sets in capacities ranging up to 75 k. w. Their bulletin "C" contains detailed information.

THE CHARLES E. GREGORY CO., Chicago, publish a revised list of bargains, in which are mentioned many new items.

THE NON-POLARIZING DRY BATTERY CO., 625 Broadway, New York, publish a letter from the Pennsylvania R. R. Co., stating their batteries are all they are represented to be.

THE STEWART ELECTRICAL CO., Cincinnati, Ohio, are in line with a long list of bargains, including dynamos, motors, arc lamps, instruments, switches, carbons, etc.

SIPE & SIGLER, Cleveland, Ohio, give their reasons why the Willard storage battery is superior to all others.

STANLEY & PATTERSON, general electrical equipment supplies, 32 Frankfort street, New York, publish a letter rela-

tive to the excellence of the "Bohemian" coloring enamel and frosting for incandescent lamps.

DIAMOND STATE TUBE COMPANY, Elsmere, Del., manufacture fireproof and waterproof tubing for electric wiring of which they are glad to send samples and prices.

NEW YORK NOTES.

MR. A. D. FRENCH, of Broad street, New York, has placed upon the market a wooden octagonal pole, which is treated against decay by antiseptics, and is practically indestructible by rot. It can be substituted, he states, for iron poles at one-half the cost, and has as long life, while being cheaper to set up. Experiments extending over 35 years have proved its success beyond question. Such poles, even if they only outlast two untreated poles, will pay handsomely in the end, as the cost of labor alone in replacing a decayed pole, will more than offset the slight extra cost. A descriptive circular will be sent free upon application. Mr. French also handles the untreated octagonals, and reports a large trade this spring, but has ample facilities to fill all orders promptly.

MICA. "The rapid growth of our business is the strongest evidence of the superiority of our Mica," appears as a preface to the 1898 catalogue of "Mica" specialties which has been mailed to the electrical trade throughout the United States by Messrs. Eugene Munsell & Co., of New York and Chicago.

THE NATIONAL CONDUIT AND CABLE COMPANY, of New York, have been calling the attention of our readers through our advertising pages to some very interesting letters which they have received from a few of the large power transmission plants which they have recently equipped with their paper insulated underground cables, and which show remarkable tests. Among them are two letters from the St. Anthony Falls Water Power Company, of Minneapolis, mentioning a cable over nine miles long, which carried 18,000 volts alternating current for over eight hours. This cable is now in regular service, transmitting 2,000 h. p. nine miles by the three-phase 12,000 volt system. Another letter is from the Lachine Rapids Hydraulic Land Company, Limited, of Montreal, announcing that the paper insulated cables supplied to them, carrying from four to five thousand volts continually, have proved entirely satisfactory. Part of these cables cross the canal and are therefore lying in water all the time. These tests show the National cables to be of undoubted merit, and should be a source of congratulation to the company. In these days of severe competition between paper and rubber insulation for high tension cable purpose, they are particularly interesting.

MR. T. E. D. RITCHIE has just accepted a position with the Fort Wayne Lamp Company, of Cleveland, O., as Eastern sales agent and will have his headquarters hereafter in the offices of the Fort Wayne Electric Corporation, at 115 Broadway, New York. Mr. Ritchie has been identified with electrical interests for about nine years, during which time he has been connected with the Edison General Electric Company, and the Chicago Edison Company, and has recently been attached to the sales department of Sargent & Lundy, of Chicago.

MR. GEORGE T. HANCHETT, E. E., has established himself at 123 Liberty street, New York City, for the design and construction of electrical machinery and models, as well as for the preparation of engineering drawings, tracings, etc. He makes a specialty of perfecting inventions and apparatus.

FRINK'S CLUSTER AND WINDOW REFLECTORS are meeting with excellent demand throughout the trade. These goods have been known as standard for many years, I. P. Frink being one of the pioneers in the reflector business. The offices and salesrooms of I. P. Frink are located at 551 Pearl street, New York. Book of lights and estimates will be mailed free to any address on application.

NEW ENGLAND NOTES

CLINTON WIRE CLOTH COMPANY, Clinton, Mass., have the call on wire cloth and perforated metals throughout the electrical field. Their goods are used on dynamos and motors, to protect the commutators, for rheostats and for any other purposes throughout the electrical trade.

F. N. MANROSS, Forestville, Conn., reports business very good. Mr. Manross manufactures hairsprings for electric indicating and recording gauges, steam guages, etc., also non-magnetic hairsprings of phosphor bronze and other non-magnetic metals. Mr. Manross is the largest manufacturer of hairsprings in the United States and is in a position to manufacture any special goods to order.

THE K. & W. COMPANY, Pittsfield, Mass., has voted to increase its capital stock, the money to be used in adding to its equipment to meet the demand. The Hardy lamp proves popular and there has been a steadily increasing demand therefor and for the new type of Absolute Cut-Out Hanger Board.

COLUMBUS, O., wants bids up to March 24, on a municipal electric light plant, to include two compound condensing engines of 125 h. p. each, 500 r. p. m., or one 250 compound condensing engine, about 200 r. p. m., with condensers; two water tube boilers, 150 h. p. each, with straight tubes; one 125 lt. 2,000 c. p. arc dynamo; three 160 lt. 1,200 c. p. arc dyanmos; two 100 h. p. impulse or turbine water wheels; ninety 2,000 c. p. arc lamps; 310 1,200 c. p. arc lamps; 1,500 white cedar poles, peeled; 50 miles triple braided weatherproof wire; cross arms, pins, insulators, etc.

Vol. XXV. MARCH 24, 1898. No. 516.

ELECTRIC LIGHTING

Two Commutator Dynamo at Hartman Carpet and Furniture Store, Chicago.

AN interesting isolated plant was started March 1 at the new store of the Hartman Carpet and Furniture Company on Wabash avenue, Chicago. It consists of a 60 k. w. double commutator Western Electric dynamo driven by a 14x14 inch Ball high speed engine. This dynamo, shown in Fig. 1, has a double set of armature windings and two commutators for the purpose of running both 110 and 220 volt circuits from the one machine. Each commutator gives 110 volts, and for lighting purposes the circuits are grouped so as to maintain approximately an equal number of lights on each side of the machine. For running the elevator motors the two 110-volt sides are connected in series to give 220 volts. The connection of the machine to the switchboard and circuits is shown in Fig. 2. The building is not wired on the three-wire plan, but has two independent two-wire circuits and a 220-volt power circuit. By suitable connections it can easily be run from the Edison three-wire street mains during the summer. Each commutator of the machine is connected to a double pole single throw switch which is connected to half of the 110-volt lighting system. Each commutator is also connected as indicated to a three pole single throw switch for the power circuit. When this switch is closed the two commutators are connected in series, but when it is open they are entirely independent. The balancing of the two lighting circuits is accomplished by wiring half of the lights on each floor to one side and half to the other.

The dynamo is compound wound. The shunt coils are run from one commutator, but the series coils are equally divided so

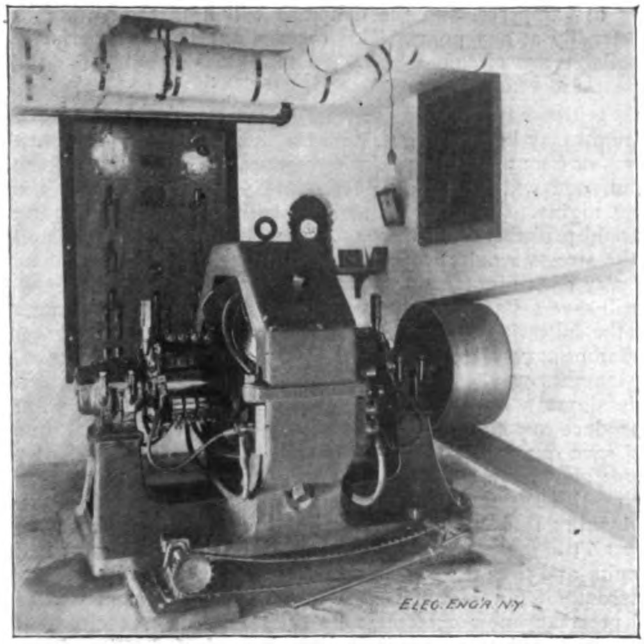

FIG. 1.—DOUBLE COMMUTATOR DYNAMO.

that half are run in the circuit from each commutator. Of course, whatever the machine compounds influences the voltage on both commutators, but with the load about the same on both sides this does not interfere with satisfactory working.

The building is wired for 629 incandescent and 46 Helios enclosed arc lamps. There are two Crane electric elevators, one for passengers and one for freight. The passenger elevator is rated to lift 2,000 pounds 250 feet per minute and the freight to lift 4,000 pounds 100 feet per minute.

The boiler plant consists of two 5x16 feet horizontal return flue boilers. It may be asked how a satisfactory service can be given with electric elevators and lights run from the same dynamo. This is provided for by making the engine somewhat larger than is necessary to drive the dynamo at its rated load.

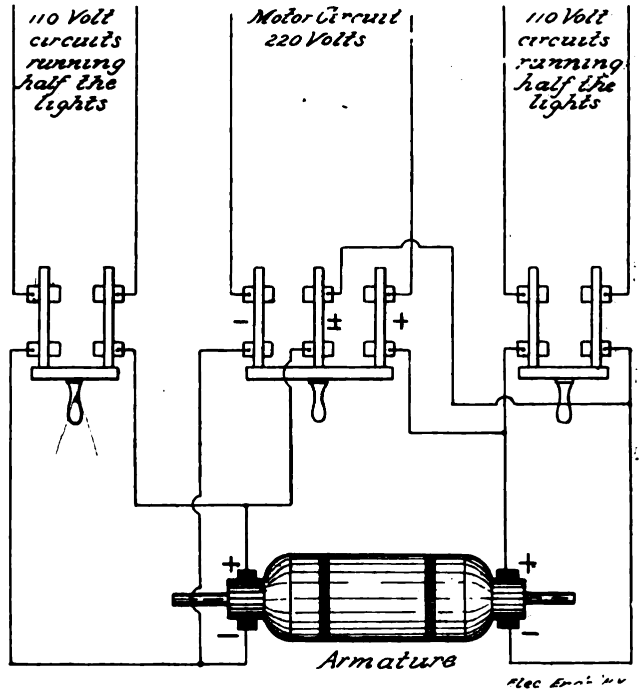

FIG. 2.—DIAGRAM SHOWING CIRCUITS FROM DOUBLE COMMUTATOR DYNAMO.

The engine gives 123 horse power at ¼ cut-off, while the dynamo is only 60 kilowatt.

The dynamo and switchboard were put in by the Western Electric Company, with F. D. Mack as consulting engineer.

High Tension Series Enclosed Arc Systems.

BY J. H. HALLBERG, E. E.

MANY articles have appeared in the pages of this journal describing the enclosed arc lamps and calling attention to their many advantages, but the writer has not seen any particular attention called to the high tension series enclosed arc lamps, which have now been perfected and are manufactured by a few firms. Probably the reason of this silence is that the manufacturers have not met with such success in designing and operating lamps on such circuits as would warrant this recommendation for street and commercial lighting.

I will first take up a few questions as to the requirements of the enclosed arc lamp for high tension series street lighting and commercial circuits. The insulation should consist of mica, lava and porcelain; fibre should never be used in arc lamps, except for switch handles. When testing insulation it is best that one should not depend on the ringing of a magneto bell, but should take one wire from the magneto in operation and connect to the ground, or to the frame of dynamo or cover of lamp; then, the other wire should be attached to a small handle and taken in one hand, while with the other hand touch some connection or bare wire in sure contact with the circuit; to be perfectly sure, the hands should be wet. It is understood, of course, that the operator must be insulated from the ground.

I have found this method to be the surest where no special testing apparatus is at hand, as one will surely feel the current from the magneto if there is a leak. One should never depend on ordinary insulation in high tension series lighting, as the extremely high pressure of the "kicks" caused by flashing of the dynamo or the breaking of a wire will break through any ordinary insulation; consequently, ground lamps and apparatus.

The lamps should be provided with a standard hanger and so designed that they will fit in the majority of hoods with hanger boards now in use. Each lamp should be provided with a cover that is easily removed for inspection. The lamp should be snow, rain and as nearly dust proof as possible and at the same time ventilated. All parts should be easily interchangeable with the use of no other tools than a pair of pliers and a screwdriver.

My experience has been that it is better to use binding posts and connectors than solder, for various reasons, the main one being that a coil can be changed without the use of a troublesome soldering iron. The cut-out should be positive in its action and have a sure adjustment, and its contact points should be easily interchangeable. It is preferable that the clutch should work directly on the carbon, as the wear of the clutch is thus reduced on account of the softness of the carbon. The lamp should be equipped with some device to prevent the slipping of the carbons. In a differential lamp the slipping could only happen during its burning, as the carbons are together during the day or when the lamp is not working. In a shunt wound lamp the device should always be in action, as the carbons in a shunt lamp are always apart except at the moment that the arc is struck. This device may seem unnecessary, but experience has proved that the best of clutches will slip in stormy weather, especially on lamps placed on tall poles, or if they are suspended from poles which also carry one or more trolley wires.

The inner globe should be easily interchangeable, as when trimming a number of lamps it is demonstrated that it is best to exchange the dirty inner globes for clean ones, and bring the dirty globes and what is left of the upper carbon back to the station, where the former are cleaned and the carbons are cut to the right sizes for negative or lower carbons for the next trimming. The lamp could be so designed that it would maintain the same voltage at the terminals and arc, whether the amperes be 4 or 7, varying, or any constant between these two numbers. A lamp designed for 4 amperes should operate on any ampereage between 4 and 7. The arc in the lamp should consume the entire voltage, as measured at hangers, except one volt. This one volt is all that is necessary to hold the cut-out open. When the lamp is cut out by its automatic cut-out not over 4 volts should be expended when the lamp coils are hot. The shunt coil and cut-out should not consume over one-tenth ampere when the lamp is hot.
